The composition of groups should always be ruled by the position they occupy. On the lawn the plants employed should be rich and elegant; in the park, or on the hillside, noble and majestic; near water, partially pendulous; and not only so, but the general aspect of the locality, and the style of house, should also be taken into account, as certain trees are more in unison with wild, and others with sylvan scenery. It is also usually laid down as a rule, that pyramidal forms harmonize best with Grecian and round-headed forms best with Gothic styles of architecture. This rule, however, must be understood as of general rather than minute application, or a most unnatural and monotonous effect will be the result.

Groups may be composed of one or more species or varieties, and, if carefully executed, with equally good results. As a rule, the plants should differ in size, in order that the outline may be more varied; if the group be of irregular form, the larger plants should be placed in its centre and salient curves, it will thus gain in dignity, and be far more natural and pleasing than if faced by a stiff gradation.

Mixed groups should be composed of such trees as harmonize or contrast well with each other. Be it ever remembered there is such a thing as harmonious contrast, and happy is that planter who can produce such effects; he builds for himself a leafy monument that will be admired by succeeding generations. W. WALTERS.

Yew Berries not Poisonous.—There has been some diversity of opinion on this point; but the learned Professor Clos, of Toulouse, has recently investigated the question, and pronounced yew berries, including the kernels, perfectly harmless. The results of his labours are given in the *Bulletin* of the Botanical Society of France.

SOMERLEYTON GARDENS, SUFFOLK.

This fine place lies on the borders of Suffolk, about six miles from Lowestoft. It is mentioned in Domesday Book, and is a place of considerable historical importance. The old mansion was entirely rearranged, extended, and altered by Sir Morton Petro, who formed its grounds, constructed and ornamented its winter garden, and otherwise greatly altered and improved the estate, which he occupied from 1844 until 1862; when it became the property of the late Sir Francis Crossley, Bart., so well known by his magnificent gift to Halifax of a public park. Quint old Fuller ranked Somerleyton amongst the best of the many fine houses in the county of Suffolk, and says that it well deserves its name,—“for there summer is to be seen in the depth of winter”—the grounds being unusually well furnished with evergreens; while the lawns and pleasure grounds in the neighbourhood of the hall are finely undulated, and covered with a thick, velvety carpet of well-kept grass. The park, which is about two hundred acres in extent, contains a large herd of deer and some noble avenues of aged Limes and Elms. Mingled wood and water add to the attractions of the locality, which is purely English-looking, pleasing, and picturesque.

Somerleyton is chiefly remarkable for its conservatories, extensive and well-kept flower gardens and grounds, and excellent forcing and kitchen gardens.

The winter garden, the roof of which is lofty, and dome-shaped to the north side of the hall. In its centre is a noble fountain, supported on rock-work by four dolphins, and surmounted by a marble statue of “The Nymph of the Lily,” from the top of which the water is thrown through a jet to a height of nearly fifty feet. Water is also emitted from a number of small jets and from the mouths of dolphins situated near the base of the rock-work. This fountain is surrounded by a basin some fifty feet in diameter. Cool-house ferns ornament the base of this tasteful display of waterworks, among which we noticed Woodwardia radicans, Scopendriums, &c.; and in this water are Callas, Valisnerias, and other aquatic plants. The roof of this winter garden is supported by light iron columns, all of which are covered with climbers, such as Passifloras, Kennedyas, Fuchsias, Tecomas, Lapagerias, Tacsonias, Mandevillas, &c.; trellises along the sides of the house in front of the glass, and also the rafters, are covered with the same elegant drapery. From the roof are suspended ornamental wire-baskets filled with plants of a suitable character. Marble statues, and vases filled with flowers, stand at regular intervals apart along the passages and other prominent situations. At the middle entrance to the hall are two aviaries, which give life and interest to that part of the building. Surrounding the grand central display of waterworks are beds filled with Camellias, Acacias, Tea Roses, Brugmansias, Hydichiums, and similar plants, planted out, the whole fringed with plants in flower in pots. Palms and tree ferns are, however, what would set this house off to best advantage, and for

which it seems in every way suitable. The corridor between the winter garden and the palm house is elegantly draped with climbers. On the right is a small fern grotto and fountain formed in a recess in the wall, which is covered all over with mosses and dwarf ferns. Standing in the door of the palm house, and looking back towards the winter garden one has a grand view not only of the corridor, but also of portions of the interior of the winter garden, with its fountain, statues, &c., the whole reflected in a large mirror, thus doubling the effect, and rendering it at once grand and imposing. The palm house, situated at the end of this corridor, is square, and not very large though it contains a goodly collection of those noble tropical plants, which are kept in tubs and pots, and have a luxuriant and thriving appearance. Bananas, tall-growing Dracanas, Monsterae, Philodendrons, and vegetation of a similar kind, are also employed in the ornamentation of this house; and along the margins are placed dwarf Ferns, Begonias, and other ornamental-foliaged plants. Iron trellises are erected in front of the glass, as is the case in the winter garden; and these, as well as the supporting pillars, are covered with the finer kinds of tropical Passion Flowers, Thunbergias, Clerodendrons, Hoyas, Stephanotis, Cissus, Allamandas, Jasmines, Bignonias, and others. These are kept neatly pruned and tied, though not too stiffly; on the contrary, they hang down in graceful festoons.

Both the winter garden and palm house are heated by means of a saddle malleable iron boiler, which works with facility the 7,000 feet of four-inch pipes used in warming the two structures. This amount of piping is divided into four flows and four returns; one set works the palm house, another passes round the side of the winter garden next the hall; the third the opposite side,

and a fourth set passes along the centre of the house and around the fountain. No difficulty has hitherto been experienced in keeping up the necessary heat, even in severe weather; but should an unusually hard winter occur, provision is made for assistance by means of an upright tubular boiler placed alongside the other, which can be worked in unison with that always in operation. Plant houses for the production of flowers for cutting, specimen soft-wooded plants for summer conservatory decoration, ferns, orchids, fine-foliaged and flowering stove and greenhouse plants, occupy a place near the kitchen garden. Besides these, there is also a span-roofed house for Oranges, the plants in which are arranged along the centre; they are in tubs, and exhibit a fine fruitful appearance. Along the front of the orange house is a bed containing cocoanut fibre, in which various stove plants are plunged, and in which they are growing finely.

In front of the west side of the hall is the Italian garden; and on a lower level is the principal flower garden, geometrically laid out and embroidered with box. In the centre of this parterre is a noble sun-dial, gilt with gold and supported on a marble pedestal. This parterre, together with the terraces, and, in fact, all throughout the pleasure and ornamental grounds, is enriched by costly marble statues,

Somerleyton Hall.

consisting of single figures and groups, and likewise many vases of handsome form. There are likewise two beautiful statues on each side of the entrance to the winter garden, some idea of the effect produced by which may be obtained from the accompanying illustration.

(To be continued.)

THE SIX OF SPADES.

CHAPTER X.

The President's Lecture—“Rosa Bonheur.”

MY DEAR BROTHER SPADES.—Like a herring-boat astern of the *Great Eastern*, I follow in the wake of grand examples, and commence my essay, as the first essayists of our “times” are wont to do, with a topic very remotely connected with the chief theme of my history. For I have nothing to say concerning that wonderful Frenchwoman, who has painted, to our great surprise and delight “The Horse Fair” and “The Denizens of the Highlands,” and have only borrowed her sweet name to serve as my text and motto—*Rosa Bonheur*, *Rose est Bonheur*, the Rose is Happiness, Felicité Perpetuelle, a thing of beauty and a joy for ever.

I go back in happy retrospect to the sunny days of childhood. I wander once more in bowery lanes, what time there were hedges in the land, and ere the face of nature was so closely shaved by the Meelian razor of improvement. It is the time of roses—wild roses, blooming fresh and fair, from cold soil and thorny stem, like wisdom and hope, from sorrow; wild roses, lighting up the land with their pure starlike glory, and beautifying the gloom of a fallen world; wild roses, on which Adam looks, as he toils with the sweat on his brow, and yearns at heart for Eden. It is the time of roses; we pluck them as we pass, and make a coronal, “mammy” and I, for my little sister’s hair. I see her now, enthroned upon some southward bank, where the oxlip and the violet have watched in their season the slumbers of the fairy queen, smiling through her tears, herself a dewy rosebud; for the briar has pierced her small tender hand, and her spirit has been startled, and has quailed awhile, at the presence and the prescence of pain. Only a moment, for the breeze which gently stirs those golden tendrils, and bears away a crown jewel in that petal which flutters to the ground, is fraught with sweet scents and sounds, with frankincense rising heavenward, and psalms from a thankful quire; and all things young and innocent must needs rejoice, Dear days of sacred gladness, fair hours of guileless love! I never see the wild rose now, but I hear sweet whispers of their “tender grace,” and I am wandering once more through the bowery lanes, with my little sister’s hand in mine.

And next I remember those roses of the garden, which, few and precious, were the delight of my early boyhood; the glorious Provence (that elegant individual, who first called this blushing beauty “Old Cabbage,”) ought to have been imprisoned for treason against the Queen of Flowers, and his diet restricted scrupulously to the humble esculent in

question); the grand Provence, which came to us, as our roses now, from the sunnier clime of France, herald of a great and splendid army, the evening star, which glitters for awhile alone ere all the firmament is thick set with gems. Ah, my brothers, what a sublime astonishment and ecstasy must this rose have caused, when it first arrived in our land! No ambassador, however copper-coloured, no hippopotamus, however far advanced in gestation, could educe such a sensation now. How the French florists must have shouted in exultation, “*magifique*” and “*tres superbe*;” they who love truth and honesty, rejoicing in the justice of their praise, and they who love to magnify and to gull “*ces Anglais*” (a class which, I am informed by buyers of new roses, is not altogether extinct), annoyed by the difficulties of exaggeration, and moaning over their inability to lie. How the writers and singers of romance must have rejoiced in this fair reality! How gaily, with this flower in his cap, must the troubadour have touched his guitar! The brave knight wore it in his helm, I trow, the gift of his lady-love, and while his adversary was gazing with wrapt admiration on it, saw his noble opportunity, and stuck a lance into his ribs. Ah, me! what tender tones, what plaintive heart-music, what hopes and fears have been sighed over this rose of Provence! Beauty hath made for it a second sunshine with her smiles, and Memory has shed upon its leaves her gentle rain of tears. How often hath this sweet messenger been made to tell unto loving hearts a language which they dared not speak! How often by lily hands have its petals been plucked and scattered in the wild hours of mistrust or jealousy, as Guinevere suspecting Lancelot,—

“ Brake from the vast oriel,
embowering vine
Leaf after leaf, and tote,
and cast them off!”

Let us ever, my friends love the Provence rose, not only for its own loveliness and sweetness, not only as the rose *par excellence* of our boyhood, but as having been for more than two centuries the chief grace and glory of our English gardens, the fair favourite (as the rose will

ever be, I trust) in every grade and shire; what time upon holy altars, in the halls of kings, in the grand gardens of the nobility, among the few flowers of the farmstead and cottage, it found a place and throne.

Growing near “the Provence” in our garden I remember next a rose, which came to this country together with it, or shortly afterwards, from Holland; I mean the beautiful Moss; most beautiful, when, like some sweet infant smiling out of its pretty head-gear of lace, or some young girl blushing to show herself before an admiring world, it first displays its loveliness “i’ th’ bud.” You shall infer, if you please, my faithful fondness for this flower from a little incident which occurred to me but a few months ago, and which I will now repeat to you.* I had been a week in London, in the height of the season, and, thoroughly enjoying the pictures and the music and the pleasant society, proposed to remain for a fortnight longer, when one day, as I walked down Regent Street, I was

* I must apologize to those who have read my “Book about Roses” for the repetition of two or three incidents herein recorded.

Entrance to the Winter Garden at Somerleyton.

addressed by an elderly Irishwoman, as a "swate gentleman" (a compliment which I was unable to return), and piously adjured, "for the love," &c., and "for the glory," &c., which, alas! meant only gin, to buy a beautiful nosegay for the girl of my heart. As the locality referred to was not at the time occupied by any young lady in particular, but by a community of beauties, I was about to decline, on account of the quantity required, and the consequent expense to be incurred, when I caught sight of a cluster of Moss Rosebuds, which I had no power to resist. Perhaps their freshness and fragrance were enhanced by contrast with their unhandsome, not to say unpleasant purveyor; at all events, I bought them from her, and they were soon rejoicing in some fresh water, and expressing their gratitude, in the little drawing-room of my lodgings, by the heightened colour of their complexion, and by the unreserved openness and general sweetness of their demeanour. It struck me, as I gazed, how far more beautiful they were than any of the elaborate works of art, for which I had deserted, in mid-summer, the country and the works of Nature; they seemed like messengers gently repriming me as unfaithful to dearest friends; they reminded me of purer pleasures; to be brief, they took me to King's Cross Station, the very day after my purchase, to my own dear roses, and my happy home!

Next in favour to the Provence and the Moss, the sweet little "Fairy" rose (*Rosa Lawrenceana*) gladdened my childhood with its tiny loveliness; and I can see our wax doll, through the powerful telescope of memory, asleep in her miniature crib, with those wee flowerets on her coverlet and pillow. For she was a Royal Princess, you must know, of amazing beauty and of boundless wealth, and rested always on a bed of roses, until she died one day a melancholy death, slowly roasting before the nursery fire by our brother Fred, to spite us. Very pretty are these Pompon roses; and as at the great poultry shows there are special classes for the pert, charming, and consequential family of Bantams, so should I like to see at our exhibitions, a Liliputian box of these mignons, decreasing in circumference from Ernestine de Barente to the Banksia.

And the York and Lancaster, flaunting in its colours, but flimsy in its substance, like some other gaudy "swells!" It was a delight, I remember, to arrange its petals, few as beautiful, upon a bit of newspaper, place over them some broken glass—(once in a desperate dearth of crystal I attacked an attic window with my battledore, and never since, I give you my honour, do I seem to have done anything half so daring)—and to call the consummation a "flower show." I thought of those rose leaves and of the broken pane, when it was my privilege to superintend the third national rose show in the Crystal Palace; and I murmured to myself very thankfully, very happily, and, I am afraid, very proudly, "the child is father to the man." Poor old York and Lancaster, it has succumbed to New Village Maids and Céillets Parfaits, and to Perles des Panachées and Tricolors of all denominations, and nothing remains to remind us of it now but the Lancashire and Yorkshire Railway.

I can but recall, in addition to the varieties I have mentioned, a white rose, whose name I never knew, but which bloomed in beautiful abundance, and much resembled Princesse de Lamballe; the Sweet-briar, whose fragrance we were wont to express, with some precious insight into the perfume business, by crushing its leaves with our small fingers; and the Old Monthly, which looked in at our schoolroom window, and tapped thereon with its buds at times, as though inviting us, like the lover of "Maud," to come into the garden, and be glad. How we used to envy those happy flowers, rejoicing in the sunlight, dancing in the summer breeze, unconscious of potbooks and hangers, emancipated from the thralldom of high-backed chairs, perfectly indifferent as to the orthography of the word *cat*, and not caring one dewdrop when who was king of where, or which was capital of what. The bees and the butterflies, when they came to call upon the rose, used to laugh, I am confident, at our bare little legs, dangling from the uncomfortable sedilia just now alluded to; the saucy sparrows twittered at our state; and the blackbirds, eyeing us from a contiguous Laurel, whistled comic songs at our expense,

They are gone, the roses of my childhood, deposed by fairer flowers. Where those six held dominion absolute, six hundred

distinct varieties have unveiled their beauty to the summer moons. They are gone from our gaze, but from our loving memory they shall never fade. I have a group of them, exquisitely painted by the skilled touch of a vanished hand, in a dear old family scrap-book, which I would not give for anything in the Bodleian Library; and I often turn to them with a tender sorrow, a grief which is almost gladness, having a hope as pure and beautiful as they.

S. R. H.

(To be continued.)

GARDENING ROUND LONDON.

(FOR THE PRESENT WEEK.)

PRIVATE GARDENS.

Indoor Plant Department.—In conservatories Camellias done flowering, and other evergreens not in blossom, receive copious syrings on bright mornings; air is freely admitted, and a slight shading is afforded during bright sunshine. Tying, thinning, staking, and keeping the plants free from insects, receive daily attention. Plants that have been forced are put out into pits or frames, and gradually exposed to the air. Stove plants growing freely, receive plenty of water at the root, and frequent syrings overhead both morning and afternoon. Euphorbia jacquiniiflora and Poinsettias that have been started after a little rest since their flowering period are now pushing freely; some of their young shoots are being taken off with a heel and used as cuttings. Poinsettias raised from cuttings every year are by many preferred to old plants, which are, therefore, thrown away after a good stock of cuttings is obtained. Free-growing plants not repotted this season are assisted with weak manure water. When Justicias, Eranthemums, Franciscas, and some other stove plants are trimmed into shape, the prunings are made into cuttings, and are inserted in pots of light sandy soil under bell-glasses in a brisk heat, and kept closely shaded. In orchid houses both temperature and moisture are being increased, and during bright sunshine slight shading is applied. Slugs, woodlice, and other insects are now being sharply looked after. Ferns growing freely receive abundance of water at the root; some syringe them overhead every warm morning; others do not, but all endeavour to maintain a liberal supply of moisture in the air, shading from direct sunshine. Filmy ferns are frequently sprinkled overhead with the syringe during the day-time, the hand lights under which they are grown being tilted up except at night, and wiped dry every morning. In addition to the ordinary shade of the fernery a piece of thin green material is thrown over them during the brightest part of the day.

Pots and Frames.—Bedding plants continue to be propagated, and such as are rooted, are potted or pricked into boxes; those a little established are gradually inured to the air, and strong well hardened plants are fully exposed, but still shut up at night. Pyrethrums, variegated grasses, Sedums, &c., are generally placed outside on well-sheltered borders, where mats can be thrown over them if necessary. Stocks, Aster, and Marigolds are sown on slight hotbeds, and, as soon as up, they are gradually inured to the air. Those up and fit to handle are pricked off into boxes and pans, and kept near the glass. Auriculas require plenty of water at the root; but great care is taken, to prevent water or drip from coming in contact with their flowers and foliage. Carnations are now sown in cold frames. Established plants are shifted into their flowering pots, and those for outdoor decoration are turned out into beds or borders. Heartsease are being sown, and established plants planted out. Bulbs done blooming are placed in frames, where they are kept rather dry, so as to induce them to ripen.

Flower Garden and Shrubbery.—Evergreen trees and shrubs continue to be transplanted, mulching the roots with litter or leaves, over which an inch or so of soil is placed. From conifers all contending leaders are removed, leaving only the most promising; when there is a deficiency of vigour in the leader, it is encouraged by judiciously removing the points of the side branches, or if necessary thinning them. Hardy ferns wintered in pots are now being planted in ferneries out of doors or in other shady spots. Annuals, such as Mignonette, Saponaria, Candytuft, &c., are sown out of doors, where they are to bloom. American Aloes are planted or plunged outside in beds, or are placed on rockwork, or in vases where they are to remain during summer; in case of frost, a mat will be thrown over them. Edgings of the harder succulents around flower-beds and borders are being made. Hollyhocks, the better kinds of Foxglove, Sweet Williams, and Rockets, are planted out where they are to remain. Gladioli are being planted, Box edgings pruned, and

[APRIL 20, 1872.]

Ivy clipped. The latter should be cut close in to the wall, even though it should be rendered leafless; in a short time it will be covered with the most beautiful bright green young foliage imaginable. Broad grass walks are being trimmed and swept, and lawns are regularly mown and rolled.

Indoor Fruit Department.—Pine suckers as soon as separated are potted. Vines are shut up early in the afternoon. Peaches and Nectarines have their shoots tied in and thinned. Figs ripening are kept drier than those swelling, to which water is abundantly given both at root and overhead. Cherries beginning to colour enjoy a temperature of 55° or 60° at night, and 85° or so by sun heat. Melons are carefully yet plentifully watered, no more than can be helped being allowed to touch the necks of the plants. The foliage is syringed freely, superfluous growths are timely removed, and female flowers fertilized. Cucumbers are treated as Melons, except that they receive abundance of manure water. Pinching is preferred to too much thinning at any one time.

Hardy Fruit and Kitchen Garden Department.—Wall trees, from which a fair crop may yet be obtained, are carefully protected. Protections are removed from Fig trees, from which the autumn set crop of fruit is removed, and the shoots are being nailed; except where too luxuriant, figs are not much pruned. Raspberries are cut back to within a few inches of the soil to encourage them to throw up bearing wood. Fruit bushes when damp are sprinkled with fresh air-slacked lime, as a preventive of insects. Asparagus beds are now in full bearing. Beds are being prepared for Vegetable Marrows, some using old dung frames, now exhausted by being in use for other things; others making them as described under the head of market gardens last week. A second small sowing of Turnips is being made. The main crop of Beet is now sown. French Beans are being put in in warm situations; some are also sown in frames for planting out the first of next month.

NURSERIES.

Indoor Department.—Stove and greenhouse plants continue to be propagated. *Sphaerogyne latifolia* is struck from pieces of the roots, like a *Dracena*, as is also *Yucca californica*. *Nephelaphyllum pulchrum* is increased by placing damp moss on the surface of the pot, and tying down so as to come in contact with the moss into which it strikes root. Each eye can thus be made into a plant. *Dioscorea* is cut up into two or three pieces, which by the end of next autumn produce good sized tubers. Cuttings of hard-wooded plants are inserted in pots half-filled with drainage, over which a little moss is placed, then some light sandy mould to within half or three-fourths of an inch of the surface, which is made up with silver sand, the whole being covered with a bell-glass. They are then plunged in cocoa-nut fibre over a hot-water tank; these are kept closely shaded during the day. As soon as fairly rooted, they are taken out of the bed and placed on side shelves to make room for others. Roses continue to be grafted. The stocks (*Manetti*) are potted in small sixty-sized pots through the winter, and are at present plunged outside in cocoa-nut fibre. In grafting, the stock is cut down to within two or three inches of the surface of the pot, and furnished with scions of the young wood. They are afterwards placed in close frames inside the propagating house. Those of previous workings that are well united are shifted into larger pots, and any producing strong vigorous growths are pruned back, unless the shoots are required for cuttings. By sulphuring the leaves, syringing with water in which sulphur has been mixed, and painting the pipes here and there, red spider and mildew are kept in check. Heaths are now being potted in a mixture of the best peat, leaf-mould, and a good addition of silver sand. Young Azaleas are also being potted. Orange trees are treated as young Azaleas during their period of growth. Tree Carnations that have done flowering have their young shoots cut off for purposes of propagation; these make strong flowering plants by September. *Bouvardia jasminaliflora*, propagated by means of cuttings, will also make good flowering plants by the autumn.

Outdoor Department.—Grafting may be said to be finished, except in the case of such things as ornamental Planes, purple Beeches, &c. Young fruit trees are being pruned, and last year's grafts, unless standards are required, are cut back. Rhododendrons, Laurels, Araucarias, &c., are being pruned into shape. Conifers sown in frames are now fully exposed during the day. When the finer kinds are grown for sale, whilst young they are lifted after their first season's growth in frames, and pricked into store pots, in order that they may be at any time safely removed. Deodar seeds, carefully put in some time ago with the hand, placing the narrow end downwards, are now up and looking well, while a few of the same sown broadcast at the same time have not yet made their appearance. Araucarias are sown in the same way in pits.

MARKEt GARDENS.

FROM Cucumbers in frames, all male flowers are removed, and too many fruits are not permitted to come forward. Some are now being sown for late succession, and others that are up are being potted singly and kept rather close in frames. Wallflowers that have had their bloom all cut for market are pulled up and thrown away, and the ground is being manured and dug for the reception of Brussels Sprouts. Some of the finest Wallflowers have been left uncut, firmly staked, and retained for seed. Blanched Asparagus is now plentifully procured from ridges in the open air, and Green Asparagus from roots planted between Gooseberry bushes and not earthered up. In alleys between four-feet beds of Radishes, Asparagus plants were planted about a fortnight ago, and now the beds have their surface drawn with hoes into the middle and dug over for the reception of Beet. The surface of the Asparagus ridges is loosened with iron rakes, carefully watching not to injure the rising shoots; this loosening allows the "grass" to come up more freely. Between lines of Gooseberry bushes where they are a good distance apart, are rows of Beetroot; the lines are drawn in the morning, left open during the day, and the seed sown in the afternoon. Beds of Cabbages and Turnips coming up are sprinkled with lime. Onions, Carrots, and other seeds sown in lines have the spaces between them run through with a narrow hoe, and all other crops have the surface of the soil about them stirred rather deeply with draw hoes. Spinach is sown thinly broadcast on plantations of young Rhubarb, and other open spaces amongst slower growing crops, so that it may be cut before they require the intermediate space. Strawberries are now being planted between lines of fruit bushes.

THE THAMES EMBANKMENT.

THE *Scotsman* throws some light upon a question much agitated in London, and which has several times occupied the attention of Parliament, but which is only imperfectly understood in the provinces. It says:—

"The history and position of the property created or improved by the Embankment of the Thames have been told before, but their substance admits of being restated with great brevity. When the Embankment was made, at the cost, and for the profit, of the metropolis, the Government, holding for the public certain property on the banks of the river, came to an arrangement by which it gave up to the body of River Conservators certain portions of that property, in consideration of the other portions being improved or increased in value by the embanking operations. The arrangement between the parties was embodied in an Act of Parliament, and each entered into what at first promised to be peaceable possession of its share of the property. It happened, however, that some people in London became of opinion that certain piece of the property left in the possession of the Government would make a very nice garden or garden-plot for the use of London people living in the neighbourhood, and that, just about the same time, the Government became of opinion that that piece of property, so belonging to the public, would be extremely suitable as the site of certain new public offices which are urgently required. Thereupon began a struggle virtually between London, or a portion of London, and all the rest of the nation. On behalf of London, it was said, through all the many whom London can influence, that it was not fitting to cover with buildings an open space in the centre of a crowded city like London. The main reply of the Government was, of course, that the property belonged, not to London, but to the nation, and that, however pleasant a little garden might be to such Londoners as happened to live near it, the little garden could not reasonably or honestly be furnished to Londoners at a great cost to the whole country besides. There were additional replies, either given in name of the Government or contributed from other quarters. Thus, it was pointed out that the very people who demanded from Government—that is, from the nation—a portion of national property, for purely local recreative purposes, had just sold to the highest bidder, to be covered by buildings, portions of their own property, quite as well suited for such purposes; in other words, London and the country, having shared the Embankment property between them, London first sold what it could of its own share for profit, and then turned round and insisted that the most valuable portion of the country's share should be reserved for pleasure, which, of course, means for the pleasure of London, or some fragment of London. Again, the corner which it is thus proposed to appropriate is not in a part of the metropolis where air and space are scarce, but is within three minutes' walk of St. James's Park; whilst, on the other hand, the corner affords a site for public offices more convenient than can be obtained anywhere else even at the most enormous cost. It is also worthy of note that, whilst other great English cities provide parks and other recreation grounds for themselves, either through the munificence of individual citizens, or by means of local taxation, London, already enjoying the free use of the magnificent parks belonging to the Crown, is here, and not for the first time—still less, if successful, for the last time—calling out that she should be provided with additional recreation ground at the expense of the country at large. And that expense is out of all proportion to the object—the garden would be very small, and its cost, measured as it must be by the cost of the sites for public offices which would require to be provided somewhere, probably be the greatest ever expended in this world upon so few yards of land."

THE GARDEN IN THE HOUSE.

BOUQUETS FOR THE HAND.

BOUQUETS for the hand should be made of the choicest flowers, gracefully arranged; heavy solid flowers or massive arrangements should be as much as possible avoided. Such bouquets are necessarily brought under the closest inspection of the eye, and should be composed of flowers of delicate structure, or great variety, or exquisite fragrance. The present style of immense size, composed of solid flowers, scarcely if at all relieved by foliage, is only suggestive of some enormous variegated or pied fungus hung with silk frings or put up in lace paper. When carried at evening entertainments, they frequently appear to be a burden to their fair possessors. For successful effect in floral decoration, much depends upon the judicious arrangement of colour; violent contrasts are also to be avoided, as is also the sameness produced by having too much of one colour. In producing harmonious contrasts of colours it should be remembered that there are only three primary colours—red, blue, and yellow. From these arise what are called the binary, or secondary colours, namely, orange, composed of yellow and red; purple, composed of blue and red; and green, composed of yellow and blue. These form contrasting colours to the primary three, with which they are in harmonious opposition, as the orange with blue, purple with yellow, and green with red. From the combination of these secondary colours arise three tertiary colours—olive, from purple and green; citron, from green and orange; and russet, from orange and purple. These tertiary colours harmonise with the primaries, as they stand in the relation of neutral tints to them, but are in harmonious opposition to the secondaries, from which they are combined. Red, blue, and yellow harmonize with each other, and they may be placed in juxtaposition, but purple should not be near red or blue, as it is composed of these two colours; for the same reason, orange should not be placed next to yellow or red, the rule being that no primary colour should be brought into contact with a secondary colour of which itself is a component part, nor any secondary colour brought into contact with a tertiary colour of which it is a component part. Another rule is that the secondary and tertiary colours, and the neutral hues arising from combinations of the primaries, such as brown, maroon, puce, slate, lavender, &c., should be used in the greatest quantities, and the primary colours used in smaller quantity for heightening the effect. If you lack the proper shades for producing the necessary harmonies, and find that two colours do not harmonise well, separate them by a white flower. Again, always place the brightest colours in the centre of your design, and gradually decrease the intensity of the tints as you approach the exterior; and avoid spottiness or patchiness by using as much as possible one prevailing colour.—*Lady's Own Paper.*

HEARTSEASE AS BOUQUET FLOWERS.

The first time I exhibited in the class for table decorations was at the Crystal Palace, June 6, 1869, when I took a prize for the floral decoration of a wedding breakfast-table. There were five stands, a centre and four corner pieces or bouquets, one of which was formed of white flowers, blue Forget-me-Nots, large dark Heartsease, and different kinds of Ferns and Mosses. It was a pretty little stand; and though some might think that blue and purple would not look well together, I can assure them that they do; the blue of the Forget-me-Not is so bright and pure, and the purple of the Heartsease so dark and velvet-like, that one sets the other off. The Heartsease which I used were nearly black.

The following season, May 1870, I also took a prize at the same place for a bridesmaid's bouquet, made up in much the same style, except that there was no blue in it. In the centre was a large white Camellia; the other white flowers were Azaleas, Stephanotis, Moss Rose-buds, and Lily of the Valley; then I worked my Heartsease into a pattern—they were purple, not very dark, just a rich purple; the only Fern I used was Maiden-hair, and I had plenty of this; it formed quite a lacework round the edge, and I also ran it through the bouquet, as I always like to see plenty of green, which sets off the colours in a way which nothing else does so well. Heartsease, certainly, as one of your correspondents remarks, looks well in bouquets or in stands on the dinner-table, but it must be by daylight, as nothing has a worse appearance by gas or under any artificial light than purple or violet flowers of any kind.

The worst of Heartsease is they are such difficult flowers to work up well in a hand bouquet, their heads being too large for their stems, and when they wither in the least they acquire such a curled and shrivelled look; but if they are only wanted to last for a few hours, and to be used by daylight, nothing has a better appearance if mixed with white and green than purple Heartsease.—A. H., Upper Norwood.

SOCIETIES, EXHIBITIONS, &c.

MANCHESTER BOTANICAL SOCIETY.

(APRIL 9TH.)

Roses and Orchids constituted the chief features of this meeting, the former principally from Messrs. Veitch, whose bushes were covered with flowers of every possible shade. The same nurserymen also showed the new Clomatis, Albert Victor (one of Messrs. Jackman's hybrids), a deep but rather dull purple flower, three inches across, every petal with a singular central streak of brown that produces the effect of a great star. In addition to Orchids, Messrs. Veitch also had some charming representatives of that good old-fashioned plant, the Primula cortusoides, long laid aside; but now, in its new Japanese forms, restored to favour. The beauty azurina, of which they had a very handsome specimen, has of late become tolerably familiar. Not so the variety lilacina, which in its class was unquestionably one of the prettiest things exhibited. The nearest idea we can give of it is that of a lilac-blue Polyanthus; but its texture and complexion far more delicate. From Mr. Linden came the beautiful Masdevallia Lindenii. Nothing could be finer in this way than Mr. Wrigley's contributions of Orchids, a class of plants which were also shown in great variety and beauty, by Messrs. James, Brooke & Co.

Mr. R. S. Yates had an Odontoglossum Alexandria, from underneath the charming flower-spikes of which peeped forth the azure-flowered Forget-me-Not. Nothing could well be prettier than the combination thus produced between the dainty and peerless Orchid of New Granada and the simple beauty of our European woodlands. Mr. John Shaw showed some nice Orchids, and a specimen of the new Primula japonica, the magenta-coloured flowers of which grow in successive tiers up the stem—the most remarkable known plant of its race. From Mrs. E. Cole & Son, came some beautifully bloomed Ixoras and other plants. Mr. W. Bury, of Accrington, sent the snow-white Lady's Slipper, Cypripedium niveum, with a couple of expanded flowers, one of the choicest things in the show. Mr. Toll sent some good Orchids, including Ada aurantiaca and Oncidium sarcodes. Dr. Ainsworth had a new white fragrant Dendrobium, not yet named; and Mr. Stevenson, of Timperley, a plant of the remarkable Cymbidium pendulum purpureum, very attractive from the singularity of its half dozen pendulous racemes, two feet long, of reddish brown flowers. The gardens at Old Trafford supplied a capital display of succulents, all rare and curious; also an Arancrum sesquipedale, and some other Orchids.

This closed the series of spring shows, and gave assurance that with their renewal next autumn the support they deserve will be even more cordially awarded.

ROYAL HORTICULTURAL SOCIETY.

(APRIL 17TH.)

The chief features of this meeting were Azaleas, Rhododendrons, Auriculas, and other spring flowers; miscellaneous plants were also furnished in good condition, as were likewise Orchids, especially a collection from Mr. Denning, gardener to Lord Londesborough, at Grimston Park, Tadcaster. Fruit and vegetables were but sparingly exhibited.

Azaleas were shown mostly in the form of pyramids, though there were a few dwarf standards with compact heads of flowers. In a group from M. Louis Van Houtte, of Ghent, were many of fine form and quality. First-class certificates were awarded to John Gould Veitch, Mille. Marie Van Houtte, and S. Rucker. Some specimens with flowers of good form and distinct in colour were exhibited in Messrs. Veitch's miscellaneous collection of plants. Of Azaleas for competition nice collections came from Messrs. Lane, Lee, and Turner; and among groups from amateurs were also some good plants.

Rhododendrons in pots, in excellent condition, were shown by Messrs. Lane, who also staged a fine box of cut trusses of bold well formed flowers of the same useful shrub. We missed the presence at this meeting of one of the best features of spring shows, viz., Roses in pots; but blooms were, however, shown in boxes, one of which, from Messrs. Kelway & Son, was wholly filled with Maréchal Niel. To this an extra prize was awarded. There were seventy blooms all from one plant, from which last week four hundred blooms had been cut for market, besides a goodly number earlier in the season. Auriculas were in admirable condition, both show kinds and alpines being equally good. Amongst the best, which came from Mr. Turner, of Slough, were Miss Giddings, Smiling Beauty, Competitor, Incomparable, Cantab, Maria Chapman, Catherine, Colonel Champeyne, Metropolitan, Alderman Wisbey, and Alderman Charles Brown. This section was well represented by amateurs. Heartsease in pots and also in the form of cut blooms were exhibited by Messrs. James, Hooper, and Ware, the last of whom also showed some good Auriculas and hardy spring flowers. Amongst the latter we noticed the beautiful Cypripedium Calceolus.

Fine groups of well-bloomed Clematises in pots were exhibited by Messrs. Veitch and Mr. Noble. Palms, Dracenas, variegated Pandanus, and other plants, came from Mr. Bull and Mr. Winscott.

Amongst Orchids four Masdevallias were brought under notice, viz., M. Lindenii, Veitchii, Harryana, and ignea, all extremely interesting and beautiful, and from the fact of their being cool-house Orchids and easily grown, they are very desirable plants, especially for amateurs. Besides these there were many others, conspicuous among which was Arthropodium giganteum, a fine plant bearing fourteen spikes of lovely blossoms. To Odontoglossum Phalaenopsis a special medal was awarded.

Dark-coloured fern-leaved Maples were amongst the most noticeable plants in the miscellaneous collections. These withhold, it is said, fully better than most plants the atmosphere of our smoky cities.

Amongst other things were excellent plants of Anthurium Scherzerianum with large well formed flowers. Interesting collections of cut blooms of Narcissi were exhibited by Messrs. Barr & Sugden, Messrs. Backhouse & Son, York, and by the Rev. Mr. Berkeley.

First-class certificates were awarded to Croton lacteum from Messrs. Veitch, with a fine broad-leaved species, with the midrib and side veins boldly marked with pale yellow; to a pretty little compact green-leaved Ivy named Hedera conglomerata, from Messrs. Ivory; to a nicely variegated form of a hardy British evergreen fern called Polystichum angulare confertum variegatum; to the Erica Neitneriana, noticed last week, from Messrs. Rollinson; and likewise to a graceful species of Rhopalà, called elegansissima, which promises to be a grand addition to our stock of decorative table plants. This came from Mr. B. S. Williams, Holloway.

Forced vegetables consisted of Asparagus, Seakale, Green Peas, French Beans, New Potatoes, Cucumbers, Mint, Cauliflowers, Young Carrots, and Mushrooms; these were shown by Mr. Clarke, gardener to J. C. Brown, Esq., Horsham, Sussex, and by Mr. T. Batters, gardener to J. W. Fleming, Esq., Mushroom Spaw, and also a boxful of excellent Mushrooms gathered from beds five months in good bearing, were shown by Mr. E. Bland, Gordon House, Isleworth. A basket of new grapes (Black Hamburg) in good condition was shown by Mr. Baldwin, Streatham. Kestrel Seedling Strawberries came from Mr. Miller, Workshops; Lemons, Limes, and preserved Chestnuts were contributed by Mr. Domenico Piccirillo.

THE BOTANIC GARDENS IN THE REGENT'S PARK.

They are arranged, says the *Telegraph*, as completely as possible in opposition to the Italian style; and we can imagine no prettier picture than an early spring fête day at the Regent's Park. Once inside the gate, you are lost in the mazes of a miniature park. No tall houses frown at you on three sides of a complete square. Stucco and brick, mortar and chimney-pots, are carefully and completely hidden from the eye. Flirtations are not carried on in a scorched Sahara, and lovers are relieved from the comments of domestic servants in the attics of fashionable mansions. It may be in London; but, at any rate, this is a true garden. No stern laws or stern gardener warn you off the grass; for all the pleasure of the fete consists in strolling along the yielding turf, sitting about, and listening to the Life Guards' band. Here are trees and mounds, and nooks and peaceful retreats. Mount where you will, a house or a chimney-pot cannot be found. Primrose Hill will be discovered at one turn, and the rise of Hampstead farther on. Here is a lake with wild fowl and rustic bridges, and there serpentine paths winding among trees in blossom, and bushes white with may. It is for this old love of ours we would plead an excuse for fickleness. Knowing the pleasure of the horticultural fêtes, and appreciating the stern art of the garden at South Kensington—valuing, as we all must, the peace and beauty of the stately terraces at Sydenham—we would still confess to a guilty retrogression as we wander in the spring-time about these old gardens in the Regent's Park.

NIGHTINGALES IN GARDENS.

THE cuckoo is usually said to be "turned down" in this neighbourhood on the 14th of April, and the nightingales will arrive about the end of this week. Our hedges and copses in the proper season abound with nightingales, which like our pure air. They cannot endure smoke. Before London overran the pleasant Thames side westward, nightingales were nowhere more numerous than in the market gardens at Mortlake and Barnes. They appeared to court the society of a suburban audience, wherever the neighbourhood was not thickly sprinkled with chimneys. But the plantations of fruit trees which sheltered them have been cut down, and crossed by railways, and the air is no longer pure enough in many spots for the inspiration of nightingales. It is not so very long ago (May 28, 1667) that Pepys, Addison, and Sir Roger de Coverley heard the nightingale at Vauxhall and Ranelagh Gardens; and on the 20th May 1712 the same sweet songster and a "chorus of birds were heard upon the trees" in the same fashionable place of resort. The gardens at Kew, and even Kensington Gardens, will doubtless presently be joyous with the song of the nightingale.

Hellingly, Sussex.

H. NEWLANDS.

Succulents.—In my enumeration of Cacti at Kew, I only mentioned five genera. Had I given all, the collection at Kew would have been 344, against 592 introduced, exclusive of hybrid varieties of Epiphyllum and Phyllocactus. Mr. Scott sets Prince Salem, of Dyke's collection at about 800; but, on reference to his catalogue of 1849, the number enumerated is only 412. The Bedford collection is now very poor, and contains old plants under new names. I also think that Mr. Scott has set the Canary Island Sempervivums too high. I have studied them at Mr. Wilson Saunders's after the importations of Dr. Bally, and at other

places, and I have only detected twenty species. Mesembryanthemums, when at their best, at Mr. Saunders's amounted to 234, with twelve not described. London enumerates 291—among which there are, however, many synonyms. After studying them closely for twelve years, I am of opinion that, when well named, 220 would include the whole. Kew possesses 157 Aloës of all sections. Names, I am of opinion, have often been given to introduced plants that would not have been applied had the authors studied the plants instead of consulted books. If Mr. Scott could put me in the way of finding more Sempervivums than are mentioned in my list, I should be obliged.—J. CROUCHER.

Repotting Agaves.—I have noticed for some time that Agaves lose their roots about this season every year, and that they make new ones, which begin to grow in June. As the old roots do more harm than good, and as by the mode which I adopt, a pot costing—say twenty shillings—is saved, I can, with confidence, recommend my plan as safe and useful. Where a collection of Succulents has to be repotted, it is not always practicable to wait for a bright morning in May. Roots of Succulents, I repeat, may be cut off or shortened when repotting with advantage. If your correspondent, "Sempervivum," will examine one of his plants three months after potting, I think he will find the roots which had been shortened dead.—J. CROUCHER.

"Fennemore and Others v. Spice."—We observe in your impression of last Saturday a report of the trial of this cause, taken from the *Times*. The result of that trial was not, as stated by you, the withdrawal of a juror, but a verdict for the defendant. The *Times* subsequently has acknowledged the error.—WILKINS, BLYTH, & MARSLAND, Attorneys for the Defendant.

ANSWERS TO CORRESPONDENTS.*

RICHMOND (our notices of Kew are delayed a little to enable us to complete full-page illustrations of the nobler structures there)—S. S. (the tender little carrots you allude to are grown in the market gardens round Paris, and imported for Covent Garden).—T. WARD (there are at least a dozen species and varieties of Scilla well worth a place in a choice collection of hardy plants).—R. A. P. (*Sedum reflexum monstrum*).

COVENT GARDEN MARKET.—April 19th.

Flowers.—Plants in pots consist chiefly of Pelargoniums, Heaths, Pinks, Fuchsias, Tea and other Roses, Azaleas, Cyrtisus, Gardenias, Orange Trees, and others; together with a great variety of hardy spring flowers. Amongst cut flowers, in addition to those of the plants already named, are Golden-rayed Lily, Stephanotis, Orchids, Heliotropes, Imantophyllums, Spiraea, Rhododendrons, Narcissi, &c. Of Ferns, too, there is no scarcity. Bouquets have invariably as a centre flower a white Rose or Camelia, around which are placed Stephanotis, Pelargoniums, Mignonette, Azaleas (mostly white), spring Heaths, blue Cinerarias, &c.; the whole enlivened by sprays of white Bouvardias, Lily of the Valley, Orchids, and Maiden-hair Ferns.

All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

Readers who may find it difficult to procure THE GARDEN regularly through the newsagents, may have the numbers sent direct from the office, at 19s. 6d. per annum 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsagents, at the railway book-stalls, and from the office.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

NOTICE.

The Conductor of THE GARDEN will shortly commence a tour of observation through the Gardens of England, beginning with the counties of Warwick, Worcester, and Stafford. Correspondents will greatly oblige by forwarding to him, at THE GARDEN Office, 37, Southampton Street, Covent Garden, London, W.C., information as to interesting gardens, remarkable trees, and other objects of horticultural interest in any of these counties.

HOME LANDSCAPES.

GARDEN BEAUTY IN APRIL.

(AT BELVOIR CASTLE.)

REAT advances have generally been made in spring vegetation as we approach mid-April. The garden begins to assume a more varied and, in many respects, richer aspect than in March, though the eye is no longer gladdened with the gold and purple cohorts of the Crocus tribe, and the brilliant yellow of the wind-defying Daffodils is somewhat dimmed. But we have gained equivalents, and more than equivalents, in the far greater variety of floral beauty rife in April; for in addition to many of the fine March flowers that still continue to delight us with profuse bloom we have a whole host of novelty bursting into luxuriant blossom, which was only in embryo during the less congenial temperature of March.

The March garden which I most enjoyed, and which I attempted to describe in the last number of THE GARDEN, formed the surrounding of the suburban retreat of one of the wealthy industrials of the great Warwickshire metropolis. It was a modest but very delightful specimen of home landscape-making, but on a very small scale; and in that respect a striking contrast to the extensive flower gardens and ornamental woods at Belvoir Castle, the present aspect of which I have adopted as a type of garden beauty which is attainable in April. The sheltered glades and flower gardens of Belvoir occupy a charming site for spring gardening, and clothe with beauty a large portion of the noble slopes, upon the highest crests of which the castle is situated.

As our party drove over from the station at Grafton, the first near glimpse of the castle, seated on the very crown of the hill, is very grand and imposing; and although I prefer the architectural aspect of several others which I could name among our baronial halls, I know of none that can compete with Belvoir in nobleness of site. The castellated facade and flanking towers rise far above the loftiest trees that clothe the steep sides of the hill to right and left, and present a sky-line, as the architects have it in their expressive jargon, which is artistically fine in a very high degree.

But it is with the lovely flower gardens, nestling among the shrubs and trees of the undulating slopes that our interest chiefly lay; and we hastened to claim as our guide the Duke's head gardener, Mr. Ingram, who responded to our call with the alacrity of a true lover of his art. Under his guidance we advanced for some distance along shrub-sheltered walks, now rising, now falling, according to the sinuosities of these charming slopes, catching at every turn enchanting glimpses of the more distant landscape between the lichen covered trunks or great gnarled branches of the forest trees, whose bases were far below us, while their crests rose high above our heads. Sometimes these glimpses were enriched with groups of wild cherry in full bloom, and sometimes with dark green masses of Yews and Pines; while the Elms were beginning to be covered with a bead-work of tender buds "as green as emerald."

At last great masses of vivid colour began to appear in front of our path, gleaming brightly between the shrubs by which they were still partially concealed. The sky, April fashion, was dark and leaden between the short gusty storms of rain and sleet, but those masses of bright flowers seemed positively shining with a light of their own in the mid-day twilight of that stormy April day. They were not like the young German lover when he compared himself to a prisoned gem, as he sighed in his love-verse,—

"I am the gem, in gloomy place,
No splendours round me clinging;
Thou art the sunshine on my face
Bright hues from darkness bringing."

These grand patches of flower colour, on the contrary, were not of the kind requiring sunshine to set them off, for they seemed to emit a light of their own—a very bright and glowing one—in the dulness of the louring April weather.

Among the thickly-wooded slopes, the first group of beds of the forest flower-garden of Belvoir formed richly glowing spaces, delightful to look upon; while similar constellations of flower-light, seemingly as beautiful, glimmered through shrubby interruptions at every turn of the path, to right, to left, both above and below. Nothing can be imagined more charming than this series of picturesque flower gardens among the wild slopes, to the different and capricious levels of which rocky stairways lead in many directions; while masses of rock lie in front of the shrubberies or within them, covered with golden Stonecrop and many other alpine plants, not omitting, of course, the great yellow Wallflower, for which the gardens of Belvoir are celebrated.

It is difficult by words to convey any sort of idea of the charming effect produced by these varied and picturesque flower beds, which are literally crammed to repletion with plants in luxuriant bloom, just as we sometimes see Primroses in some sheltered lane covering a bank that exactly suits them so closely that neither space nor speck is left uncovered; or as Wood Anemones often make a closely packed crowd of beauty in some lonely dingle, of which they have long claimed and held undivided possession.

The only way to describe these masses of fair spring flowers so as to give some slight idea of their charm, will be to resort to individual portraiture. Happy contrast of colour has been, above all things, well considered in the distribution of the plants, and we therefore get effects of the following kind:—A large mass of Alyssum, for instance, forming a compact mass of bright yellow blossom, is placed in close juxtaposition with a still larger patch of purple Aubretia; and beyond, there is a group of deep orange Oxlips, telling out against a clump of deep blue Wallflowers, the whole composition blended and united by means of pretty plants in which delicate green foliage predominates over their flowers.

In another bed, crimson Daisies with variegated leaves are the chief feature, relieved by the great lilac flower-bunches of Saxifraga cordifolia, whose large heart-shaped and fleshy leaves give it the aspect of some tropical plant that ought to require a southern sun to bring its massive beauties of flower and foliage to perfection.

In another bed, masses of Myosotis sylvatica make a carpet of celestial blue, mingling their soft hues with double white and double yellow Primroses; the whole blended together by the deep green of mossy Saxifrage dotted sparsely over, with its sparkling white flowers that shun like little stars.

Another set of combinations consists of wide-spreading tufts of the lovely Omphalodes verna, with its flowers as blue and as pretty as Forget-me-Nots, peeping out thickly from its dwarf forest of deep-green leaves. These masses are divided by great tufts of Arabis albida, with flowers of dazzling white, that well deserve the popular name of Mountain Snow, by which the plant is known in some parts of England. To vary the height of the plants, a few specimens of the taller-growing Fleabane are introduced, whose composite flowers of ochreous yellow, balanced on their slender branching stems, have a graceful effect; while, to complete the composition, a touch or two judiciously introduced of some deep-flowered Polyanthus, or a tuft or two of the lovely Scilla verna, with delicately tender tones of azure, are made to form the climax of colour.

In some of the beds the gold-leaved variety of the common Lamium maculatum, is made to form telling patches of a peculiar orange tone, varied by others of the yellow-leaved Feverfew; among which plants of blue, purple, and tricolored Pansies form conspicuous touches of magnificent and effective colour; variegated here and there by three or four flowers, in groups, of an early dwarf Iris, the blooms, which are pearly white, blotched at the tips of the petals with a single broad mark of the deepest purple. These are but a few among the hundred combinations in this fairy-like flower garden; each one seeming more successful than the last; and then, a number of other flowers are profusely introduced, the mere names

of which would convey no definite idea to those unacquainted with the plants themselves; yet one or two beds, formed principally of varieties of *Epimedium*, should not be passed over without note, for the peculiarity and elegance of the flowers, especially that of *Epimedium rubicunda*, is so remarkable, and the plant is so hardy, that it ought to be in more general cultivation as one of the very choicest of our early spring flowers.

Then there are in the shrubberies the large yellow bunches of *Berberis* flowers, of several species; and *Rhododendrons* already threatening to burst into bloom on the slightest invitation from a more genial temperature; and the double flowering Peach is in full flower in sheltered places, where its blooms look like miniature Roses. But at Belvoir, in April, it is the flower beds among the woody dells that make the garden beauty of the place. A beautiful display of bloom has been enjoyed there from the beginning of February, and all from hardy denizens of our gardens that the poorest cottage may grow.

NOËL HUMPHREYS.

NOTES OF THE WEEK.

— WE are glad to hear that exertions are being made for the preservation of Clapham Common. We hope it may share the fate of Wimbledon, and be secured to the public for ever.

— THE *Australasian* reports that gardeners in Victoria, for the best situations near town, get from 45s. to 55s. per week; ditto, for the country, 45s. to 50s.; inferior hands for the country, 12s. 6d. to 18s. per week with rates.

— THE *Manchester Examiner and Times* of April 2nd gives along account of a grand marine aquarium which it is proposed to build at Manchester, and which shows the interest which is felt in scientific studies in the northern capital.

— At the first annual meeting of the British Gardener's Mutual and Self-Supporting Society held recently at Bristol, it was reported that 105 members had been enrolled during the past year, and that there was a balance of £22. 6s. 6d. in hand. Officers and members of the committee for the ensuing year were appointed.

— THE Markets Committee have reported to the Court of Common Council, recommending that the Farringdon Fruit and Flower Market should be reconstructed as proposed, at a cost not exceeding £150,000. The rents, it is anticipated, will be increased from an average of £712 a year to £9,592, and the tolls and casual lettings from £507 to £4,000. The council have adopted the report, and given the committee authority to apply to Parliament for the requisite powers, and to raise the necessary sum.

— We have just received from Mr. Richard Nisbet, Aswarby Park Gardens, Falkingham, a magnificent sample of Lady Downe's Seedling grape, six months cut from the vine, and preserved in bottles of water ever since. Surely, this, among other recent examples in the same way, proves more than ever was claimed for the system. If grapes can be kept in perfect condition for six months after being cut, no grape-grower need allow his houses to be encumbered and his time lost by preserving his grapes through the winter hanging on the vines.

— Two years ago, says F. Barillet, in *Revue Horticole*, one of my friends, who was suffering from toothache, thought he would try the effect of cutting a piece of the stem of the *Araucaria imbricata*; and taking some of the sap (resin), which has the appearance of a white paste, and which is compact, he made a little ball of it, which he placed in the hollow of the tooth. Some hours afterwards the pain ceased, and the substance which still remained in the tooth answered all the purposes of the best stopping. Since that time the sap (resin) has become very hard, not only has it never moved, but my friend has not since experienced the last pain.

— THE Wimbledon Common Committee having by the passing of the Act fully accomplished the purposes for which it was formed, viz., the securing in perpetuity for the public enjoyment the whole of Wimbledon Common, Putney Heath, and Putney Lower Common, open and unenclosed, Mr. John Murray, on Wednesday evening, to celebrate the event, entertained the following members at dinner in Albemarle Street:—Mr. Alderman Besley, the Rev. Dr. Huntingford, Messrs. Benecke, Barrell, Devas, Dryden, Du Buisson, Du Cane, Hardwicke, Hussey, Jackson, Peek, Pollock, Reeves, and Williams. In the course of the evening the committee presented to Mr. Peek a silver cup and cover of most elaborate workmanship, bearing the following inscription:—“Presented by the Committee for the Preservation of Wimbledon and Putney Commons, to Henry William Peek, Esq., M.P., their chairman, as a mark of their sense of his zeal, energy, and liberality, which effectually contributed to the successful termination of a long and obstinate struggle, and thereby secured the use of the commons, free and open, to the public for ever. 1871.”

— YESTERDAY we had the pleasure of seeing a meadow to the north of London dotted over with the gracefully suspended bells of the snakeshead *Fritillaria Meleagris*, one of our most beautiful native plants. In a cultivated state it may be often seen in cottage gardens, but it is far too often absent from large places. In its several varieties we know of no more beautiful ornament of spring, and, in consequence of the pendulous character of the flower, it does not suffer from bad weather, as many other spring flowers do.

— THE opening of the People's Gardens (pleasantly situated at Old Oak Common, near Willesden Junction, and upwards of fifty acres in extent), for their third season, is announced to take place on Saturday, the 4th of May. During the winter several important improvements, both in the buildings and gardens, have been carried out, which will add greatly to the comfort and accommodation of visitors; while the train accommodation is also largely increased, trains continually arriving at the Willesden Junction from all stations on the Metropolitan and district lines, and also from the Euston and Broad Street stations of the North-Western line.

— THE Duchy of Brunswick, M. Koch informs us in his “Wachenschrift,” intends to publish statistics of the gardens in that part of Germany. The information that will be furnished will be, first, the name of the present proprietor and that of his predecessor; second, the date at which the garden was made; third, the name of the gardener who traced and put into execution the plan of the garden; fourth, the extent of the land cultivated; fifth, the number and extent of its glass houses of all kinds; sixth, minute details as to trees and rare shrubs, as well as their approximate dimensions, ages, and origins; seventh, information of another kind of which it is impossible as yet to give an idea.

— ONE of the most agreeable promenades of Paris, combining at the same time science and amusement, is without exception that of the Garden of Acclimatisation in the Bois de Boulogne. The late events caused it to be closed, but it is again open to the public at the same hours and regulations as before. A great part of the damage done has been repaired, and already there are many animals in the park. The ornamental and horticultural part has not been neglected, and the work is being actively carried on, so that in a short time all will be again in order. Amongst the greatest novelties lately introduced, and one which merits particular attention, is the *Cerasus Lannesiana*, lately sent from Japan by M. Lannes de Montebello.—*Revue Horticole*.

— THE authorities of California have engaged a professional arboriculturist, at a salary of 15,000 dollars per year, to attend to the setting out of forest trees in different parts of the State. They never, says the *Rochester Express*, did a wiser thing. Our forefathers found two fancied enemies when they landed on this continent—the Indians and the forests. They at once proceeded to exterminate both, and their fury, transmitted to their children, has been nearly successful. We may never regard the Indian as a friend, but our feelings towards the forests have changed. We want trees judiciously distributed everywhere—on the mountain side, in the fields, along country roads, in front of city residences, in parks and gardens; everywhere some, nowhere too many.

— “NATURE” records the death of *facile princeps* the most eminent of vegetable physiologists, Professor Hugo von Mohl, which took place on April 1st, at Tübingen. Von Mohl was born at Stuttgart in 1805, and in 1835 was appointed professor of botany and director of the Botanic Gardens at Tübingen, a position he has held ever since. Conjointly with Schlechtendal, and since his death with Professor de Bary, formerly one of his pupils, he has been editor of the weekly “Botanische Zeitung” since its commencement in 1843. He was one of the foreign members of the Linnaean Society, having been elected as long ago as 1837. Von Mohl has been a copious and most accurate writer on subjects connected with vegetable anatomy and physiology.

— THE Neil Bequest—in the gift of the Council of the Royal Caledonian Horticultural Society for the time being—has been voted to Mr. Andrew Turnbull, gardener to the Earl of Home, Bothwell Castle. We believe it amounted to the sum of £65. The late Dr. Neil bequeathed the sum of £500 to be invested, and the interest to be voted either biennially or triennially to a distinguished horticulturist or botanist. Scotch gardeners have long known and appreciated the worth of Mr. Turnbull as a man, and his abilities as a practical gardener. His success as a cultivator of heaths, and as the raiser of some of the most valuable and decorative among them—chief among which are *Bothwelliana alba*, *Marnockiana*, *Turnbullii*, &c.—entitle him to the highest honours which it is in the power of horticulturists to grant. He has been upwards of forty years in the service of the Bothwell Castle family, and is in every way well worthy of the mark of distinction thus conferred on him.

THE FLOWER GARDEN.

THE ALPINE GARDEN.
(Continued from p. 464.)

In numbers of gardens an attempt at "rockwork" of some sort has been made; but in nine cases out of ten, the result is simply ridiculous; not because it is puny when compared with Nature's work in this way, but because it is generally so arranged that rock plants cannot exist upon it. The idea of rockwork arose at first from a desire to imitate those natural croppings out of rocks which in temperate and cold countries are frequently covered with a dwarf but beautiful vegetation. It is strange that the conditions which surround these, and their texture and position, should rarely be taken into account by those who make rockwork in gardens. Numerous places occur in every county in which a sort of sloping stone or burr wall passes as "rockwork," a dust of soil being shaken in between the stones, and the whole so arranged that, if you do cover it with suitable plants, they perish speedily. In others, made upon a better plan as regards the base, the "rocks" are

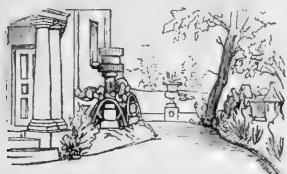

Alpine Plants growing on the level ground.

all stuck up on their ends, and so close that soil, or room for a plant to root, is out of the question. The best thing that usually happens to a structure of this sort is that its nakedness gets covered by a Cotoneaster, or some friendly climbing shrub, or some rampant weed; of course to the exclusion of true rock plants; but in most cases the rockwork is a standing eyesore.

In moist and elevated districts, where frequent rains and showers keep porous stone in a continually humid state, this straight-sided, stone-wall-like rockwork may manage to support a few plants; but in by far the larger portion of the British isles it is quite useless, and always ugly. It is not alone because the mountain air is pure and clear and moist that the Gentians and like plants prefer it, but because the elevation is unsuitable to the coarser-growing vegetation; and our alpines have it all to themselves. Take a healthy patch of *Silene acaulis*, by which the summits of some of our highest mountains are sheeted over with rosy crimson of various shades, and plant it two thousand feet lower down in suitable soil, keeping it moist enough and free from weeds, and you may grow it to perfection; but leave it to nature in the same neighbourhood, and soon the strong grasses and herbage will run through and cover it, excluding the light, and finally and quickly killing the hardy and vigorous but diminutive Moss Campion.

Although hundreds of brilliant alpine flowers may be grown without a particle of rock near them, yet the slight elevation

"Rockwork" against a House at York. Sketched 1871.

given by rockwork is very congenial to numbers of the most valuable kinds. The effect of a tastefully disposed rock-garden is very desirable in garden scenery. It furnishes a home for many pretty native and other interesting plants, which may not safely be put elsewhere; and therefore it is most important that the most essential principle to be borne in mind, when making it, should be generally known.

The chief mistake generally made is that of not providing a feeding-place for the roots of the plants that are to embellish the rockwork. On ordinary rockwork even the coarsest British weeds cannot find a resting-place, simply because there is no motherly body of soil or matter into which the descending roots may penetrate, and find nourishment sufficient to keep the plant fresh and bright and well in all weathers. It is not

Alpine Plants growing in level sandy border. June 1871.

only those who make their "rockwork" out of spoilt bricks, cement, and perhaps clinkers, that err in this respect, but the designers of some of the most expensive works in the country. At Chatsworth, for instance, and also to some extent at the Crystal Palace, you see rockwork not offensive so far as regards its distant effect in the landscape; but, when examined closely, it might well be imagined that rockwork and rock plants were never intended for each other's company, so bare are many of these large works of their proper and best ornaments. They are generally pavements of small stones, huge masses of rock, or imitation rock formed by laying cement over brickwork, and in none of these cases are they adapted for the cultivation of high mountain plants.

It is quite possible to combine the most picturesque effects of which rockwork is capable with all the requirements for

Properly formed Rockwork, suited for bold and luxuriant types of Vegetation.

plant-growing; but, in the case of extensive rockwork-making for the sake of its picturesque effect, the owner must either call to his aid a landscape gardener of some skill in this way, or possess much taste and knowledge of the work himself. It is easy to use the largest stones and make the boldest prominences, and leave at the same time rather level intervening spaces of rocky ground in which rock plants may luxuriate.

(To be continued.)

A PROTEST AND A SUGGESTION.

Who is an ardent amateur, and has not suffered from the insatiate appetite for gathering garden flowers which possesses most of the fair sex?

Whilom he was wandering among his favourites, here prostrating himself on hands and knees before a precious alpine unveiling its beauties for the first time in his possession, or there tending to the wants of some more stately foreigner; his heart fails beneath his dusty waistcoat to hear the ominous click of the garden wicket, and enter—in broad-brimmed hat and tan gloves, with gaping basket and hungry scissors—the fair form of the destroyer. If it is in the warm spring season, he shall endure the crueler pangs; for snip, snip, snip, goes the ruthless steel among the fair spring

flowers. See how the tender blue of that favourite clump of Grape Hyacinths disappears before her; bright Tulips fall apace; even the humble Dog's-tooth Violet is not spared. All, all are ravished to linger out a few dark hours in the dry twilight of the sitting-room or the greasy steam of the dining-room. It is in vain he tremblingly hints that they are far more beautiful springing from their native mould, rife by the bees, than languishing in a gaudy jar among the incongruous ornaments of a modern drawing-room. "Oh, you grizzly bear! how can you be so selfish?" or some such affectionate reproach makes him feel as if he were the evil-doer; he sighingly turns away, and dares no more. If it be summertime, he rejoices to see how long she lingers among the gaudy bedding-plants; he cares little how many of them she takes—"tis their vacation, Hal." But see, she turns her steps this way. No, no, unhappy man! in vain you interpose your portly form between that new bright Larkspur and her brighter eyes; it is in vain you hurry past you opening Rose, and try to withdraw her from the corner where your last investment in Lilies fills the air with fragrance. If, indeed, you are fortunate in exacting a tardy assent to let them blow a little more, you know too well that when next she goes on a raid you may not be there to stay her hand.

"But are we to have no flowers in the house?" will rise to the lips of any lady who has read thus far. So you shall, so you ought; but instead of having nothing but dying bouquets, let some of them be living. Some flowers seem made for cutting, and are better thus than otherwise; and all are better for cutting in moderation. Who would willingly forego bunches of Violets, Primroses, and Wallflowers in spring? or vases of Roses in summer? But, oh, for a little judgment, a little moderation, a little of the real love of flowers which makes the hand pause in time, and when it does cut offers a half apology for the assault.

And here is a simple plan, which will prove a boon to the owners of small gardens, and be to some extent a substitute for cut flowers, especially in spring, when flowers are so short-lived. It is this: Arrange now in pots the roots of spring flowering plants, so that they may flower together, and may be moved into the house for a few days when in the height of their beauty. They will require no protection in winter; only let the pots be plunged to the rim in sand or cinders to prevent them cracking in frost. If this is carefully done, if those plants which flower together are carefully grouped, charming living bouquets may be produced, and a succession be kept up for a constant supply to the house. Thus, for a February pot we may have a variegated Arabis in the centre, surrounded by purple Crocus, winter Aconite, pink and white Dog's-tooth Violet, and a carpet of the golden-tipped Stonecrop. A month later we may have a pot of Canadian Bloodroot, Grape Hyacinths, yellow Alyssum, alpine and other Primroses, and Erica carnea. The combinations are endless, and of endless interest and beauty; and, by substituting hardy Stonecrop for Lycopod or Selaginella, might well be adapted for the mode of table decoration recently proposed.

So may we have fresh garden flowers in any quantity in the house, without spoiling the beauty of the beds.

SMONICEPS.

THE ROSE SECRET.

As the Rector of Caunton has vowed not to divulge his secret relating to the propagation of roses, we may now make a selection from the articles that have appeared in THE GARDEN on the subject, as to the mode that is likely to suit amateurs and gardeners best. Nurserymen and gardeners, who have plenty of glass erections with bottom heat, can doubtless strike and grow great quantities of roses from buds or cuttings; but for amateurs and others without glass, the plan of striking rose cuttings in October in the open border will be found to answer best. The extract from a French work on a way to propagate roses from cuttings, given by Mr. T. A. C. Firminger in THE GARDEN (page 457), points out a new way of inserting the cuttings in the ground, and may be tried by those fond of experiments. I never, however, find any difficulty in striking rose cuttings without their shrinking or dying away, if properly made and inserted pretty deeply in a light sandy soil in October, and protected a little from severe frosts during the winter and spring months. With regard to the limited quantity of rose cuttings I generally strike every year to grow

on their own roots, I find the following mode answers best:—From six to eight cuttings are inserted in pots in October, and the pots are kept in a cold frame till the spring, or are placed at the bottom of a wall, where they can be covered over with some litter in severe weather. When they have made shoots two or three inches in length, and all danger from frost is over, they are planted out of the pots with their balls entire in well-prepared soil. This prevents their roots, which are very young and brittle, from being broken off, and in the summer they spread them all round from the old ball of earth and form fine strong plants, which are lifted singly in the autumn for potting or planting out as desired. It may not be generally known to amateur gardeners that they may strike roots of young apple and pear trees from cuttings like roses by putting them in October in the open border in rows. If a small heel of the old wood is attached to each cutting, it will strike sooner and make the stronger plant. Some kinds of apples of the "Burr" variety will grow when large branches are planted and will bear a crop in the second year after being planted.

WILLIAM TILLEERY.

[Mr. Hole has not the nurseryman's permission to make public the new mode of rapidly striking roses. Of "Y.'s" secret we cannot speak; but we are authorised to say that none of our correspondents who have sent so many excellent hints as to various modes of striking roses, have touched upon the mode in question.]

SPRING FLOWER GARDENING.

I HAVE thought many times lately that it would not be a bad idea if, now that one's spring beds are at the height of their beauty, every gardener who has such beds would furnish you with an account of what combinations and arrangement of colour and beauty had been most attractive and most admired with him. We should thus hear of many things with which some of us are at present unacquainted, and all of us would learn something to our advantage about our favourite pursuit.

I will begin by describing, as best I can, a few of my beds. Two corner beds here have been for a month past a blaze of beauty. They are round, and seven feet in diameter. There is a nine-inch wide ring next the grass of Cerastium tomentosum; next a nine-inch wide ring of purple Aubrieta; then the body of the bed is of the common Primrose and scarlet Duc Van Thol Tulip, plant for plant, with a yellow Pottsbakker Tulip in the centre. Bright and beautiful indeed they have been, and are. The two next beds to them are round ones, the same width in diameter, and are drawn out in pentagons. In the centre, which consists of Pansies and Golden Prince Tulip, is one plant of Vermilion Brilliant Tulip. The lines of the pentagon are marked out by means of variegated Arabis—two very neat and pretty beds. The next bed has the centre much raised; the edge begins with a ring of Sempervivum californicum (too dull in colour, its brown tips being too much the colour of the soil, for effect); next a ring of Golden Feather Pyrethrum; then the body of the bed is carpeted with Purple Aubrieta and Proserpine Tulip, growing through all over it. Inside the ring of Golden Feather is a ring of Grand Vainqueur Hyacinth. This combination and arrangement makes up a very striking bed. One bed here has an edging of the most beautiful mixture of colours imaginable, obtained by means of two common flower-garden plants—purple Aubrieta and variegated Arabis planted alternately; these make the most charming edging to a large bed which it is possible to conceive. The centre of this bed is rather a failure; it is too cold. Next the edging is a line of Viola lutea, and common Duc Van Thol Tulip, plant for plant; then the body of the bed consists of Cliveden Blue Pansy and White Snow Tulip. This arrangement is too cold. There ought to have been some scarlet alternated with the Blue Pansy and White Tulip. We have another long bed which is rather difficult to describe. It forms the segment of a circle, backed up by evergreens, in front of which are red Wallflowers. The bed itself is vandyked and carpeted with Myosotis dissitiflora and with Sedum acre aurum, through which grow Golden Prince Tulip, and Roi Cramoiso (scarlet), and the edge next the grass is double red Daisies.

N. H. P.

SPRING MIXTURES.

My best mixture for spring beds is an irregular combination of something approaching to plant for plant of the common Primrose and the lovely Myosotis dissitiflora. I call it irregular, because it is actually so; no exactness as to distance being aimed at. But the varying sizes of the plants render it still more irregular. It is, however, none the less beautiful on that account. Here a long path of Forget-me-Not spreads out and predominates over the Primrose; and anon a fine Primrose, with a head all flowers, has the

mastery over the blue. Neither is the mixture the worse for a dash of a third colour; reminding one of the flavour of hyson in a cup of souchong. Many of the early flowers of the *Myosotis* have a dash of purple, which merges finally into blue. This purple gives a certain piquancy to the pale tint of the Primrose on its first appearance, and finally merges into blue, leaving but two colours in the mixture.

These two common hardy plants are admirably adapted for balancing each other, and bringing one another out into higher beauty. The relative proportions of each may be varied in various ways. For instance, the ground may be covered with Forget-me-Not, and the Primrose dropped in regularly or irregularly, in single plants or grouplets, for effect. Or the relative position of the two may be reversed, which, however, is hardly so striking. Or, again, irregular masses of each may be placed side by side, or be made to run out and in amongst each other, as if an erratic March wind had scattered them out of its guinea-a-bushel dust measure.

It is astonishing what magnificence and grandeur come of the massing of common things, on the principles of harmony or contrast, or by the massing alone. And such an aggregation of the force of numbers is by no means unnatural. On the contrary, it is nature's method. She masses almost everything, from the green grass upwards. Look at that moor or mountain, a-glow with furze or flaming with high-coloured heaths. Place one, two, a dozen, in little coteries, how poor and tame; gather them into aggregates of thousands, tens of thousands, millions, and they grow into a grandeur and magnificence beyond the reach of words. But this apology can hardly be needed to vindicate my spring mixture. There are many other spring plants equally or more effective. The great points are congruity of habit and simultaneity of flowering. To all in search of a new sensation in spring gardening, I can with confidence recommend my mixture, in any proportion that is preferred, of the common Primrose and the *Myosotis dissitiflora*.

Perhaps the next best plant for mixing or grouping with the primrose is the charming navelwort, *Omphalodes verna*, being smaller and wholly different from the *Myosotis*; the blue is darker, and perhaps more lovely. It does not make such a brilliant display, as there is more leaf in proportion to flower; but the flower has an elegant beauty and a colour wholly unique. A groundwork, not too thick, of common primroses, with a few plants here and there of the *Omphalodes* creeping about and among it, is charming. Perhaps this plant is even more effective planted in the same way among any of the varieties of white *Arabis*. The *Aubrietas*, again, are lovely against or mixed in with white. One of the best spring mixtures I have seen was composed of *Aubrietas* and white *Violets*. The variegated *Arabis*, again, makes a splendid carpet on which to exhibit either the Forget-me-Not, *Aubrietas*, or blue *Violets*. Again, the grand old plant *Iberis sempervirens* never looks so snowy white as when matched with *Myosotis dissitiflora*. Again, if you want to see the *Alyssum saxatile* in all its golden glory, place it near a great patch of blue sky; the same Forget-me-Not. I offer one more example of spring mixture; the ground carpeted with blue *Violets*, *Nemophila insignis*, or, better than either, *Myosotis dissitiflora*, and say ten thousand golden Daffodils towering over it—a golden cargo on an azure sea.

D. T. FISH.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Linaria genistefolia.—Among hardy garden perennials that will grow on almost any soil, there are few more ornamental and desirable than *Linaria genistefolia*. It forms a compact bush, about two feet high, covered with broadly lanceolate glaucous green leaves. About July it is completely smothered with bright yellow, long-spurred flowers, which continue to cover it with golden beauty as long as the autumn frosts hold off. This species of *Linaria* is, I believe, a native of Austria. It seeds profusely, and may easily be increased by means of cuttings or division of the root.—H. HARPER CREWE, the Rectory, Drayton-Beauchamp, Tring.

The Golden-rayed Lily.—Mr. Vick, of Rochester, New York, directs attention to the long time during which this noble hardy Lily may be had in flower. He says it is one of the earliest Lilies to flower, and also one of the latest. About the first of July the first buds opened, and to-day (September 1st) I have hundreds in full bloom, with almost ripened seeds, perfect flowers, and half-formed buds, in the same row. For some years I thought this was due to the fact that the bulbs were imported, some of them being dried or otherwise injured or retarded on the passage from Japan. This idea I have abandoned, as several hundreds that have been in my grounds for three years show the same habit. What a glorious thing it is that with a dozen or so of bulbs we can have this Lily in flower all through the summer!

Buckinghamshire Orchids.—I know well the locality described by Mr. Elliot in THE GARDEN at p. 456; and most of the plants which his names are likewise well known to me as growing there. I suspect, however, some error as to *Listera cordata*; and *Epipactis purpurata* is doubtful. For *Pyrola media*, *P. minor* should certainly be read; and the *Habenaria bifolia* belongs to the form known to botanists as *H. chlorantha*.—JAMES BRITTEN, British Museum.

Dwarf Scabious with large Double Flowers.—This is deserving of notice, not only on account of the dwarf and exceedingly fine-flowering tufts which it forms, but also for its flowers, which are larger, fuller, and more double and rounded than those of the old dwarf kind. Sufficient attention is not paid to these plants, which grow without trouble in any soil, and flower profusely all the year through; the flowers are particularly well adapted for bouquets on account of their agreeable perfume, their lasting qualities, and their lively and diversified colours.

Buttercups and Geese.—Many of the richest pastures are yellow with buttercups every spring, and yet everyone must acknowledge they are injurious weeds. Injurious in themselves they take up the room of good grasses. I once heard a person strongly contending that all pastures in which they abounded ought to be broken up, well cleaned, and resown with grass seeds. I think few practically acquainted with valuable pasture would be inclined to take this strange advice. But there is one enemy of the buttercup which is often a welcome guest at our tables, and that is the goose. The goose is very fond of buttercups, and shows great determination to get at their roots, the only part it eats. Believing, as I do, that no other poultry pay so well for keeping as geese, it often surprises me that more are not kept. Is it because their utility as weeder of our pastures is not generally known? Who ever saw a buttercup on a common fed by geese?—J. R. PEARSON, in "Field."

FERULAS, OR GIANT FENNELS.

THESE belong to the same large natural family of Umbellifers as the *Heracleum*, and it will be at once evident, by a glance at the illustration on next page, that if the Giant Cow Parsnip, to be taken as an example of stately vigour and development, to this must be assigned the more chaste attributes of elegance and refinement.

View the plant as here represented of *Ferula communis*, no artist's fancy, as some may suppose, but a veritable specimen of nature printing, indeed, no doubt, to the skilled hand of the artist for the airy gracefulness and feathery lightness of the verdant cushion, from whence arises the erect branching panicle of blossoms to a height of fully six feet, charming in its rigid, finely-chiselled angular divisions, and rich in contrast with the feathery foliage below. We would add a descriptive touch, which the artist cannot give without the aid of colour; and, to complete the picture, you must imagine that the foliage does not represent one uniform tint of green, the gradations from light to dark colour being almost as numerous as the leaves themselves, and so intermingled and blended by the interlacing of the segments, as almost to defy the most skilful colourist to depict. Nor is the flower-stem deficient in this respect. In its young state, it is suffused with a tint of greyish colour, that vanishes with the touch, like the bloom on the grape.

The flowers, borne in beautifully radiating umbels, though not large nor individually conspicuous, are of a yellowish colour, and are succeeded by a goodly crop of fruit—first of a golden yellow, and, as it approaches maturity, deepening in colour to a brown. It might be supposed that a flower-stem of this magnitude would, of necessity, require some artificial support, if not when in blossom, at least, when weighed down by the bountiful harvest of fruit. But, no; nature has made a wise provision in the solidity and strength of the main stem.

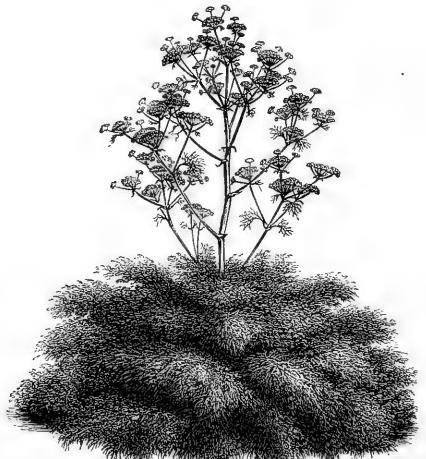

Unlike the generality of Umbellifers, the stems of all the *Ferulas* are perfectly solid and woody, and when fresh cut, just as the fruit is beginning to ripen, they are of enormous weight compared with those of any other herbaceous plant.

Fragments of the leaves, when fully matured, are admirably calculated for decorating a vase of flowers. I say when fully matured, as when young they soon become flaccid; and even when in the state recommended, care must be taken that they all have access to the water, else they soon lose their shining beauty; for this reason, they are not adapted for hand bouquets, however elegant in appearance they may be. But methinks I hear some of my fair readers taking exception to an imaginary attribute conveyed in the name, "Giant Fennel;" and saying, "What about the smell?" I grant you at once that

such a peculiar and monopolising odour as the herb Fennel possesses would be a most undesirable ingredient in a bouquet, however desirable in a sauce or a salad; but our plant possesses no smell whatever—at least, in the leaf. Indeed, it belongs to that section of the order characterised by yielding gum resinous matter from the root; whereas, the Fennel belongs to the carminative and aromatic section.

These remarks, with the assistance of the illustration, will, I trust, awaken a wish in every person possessing a garden, and who has not yet become—if I may use the term—personally acquainted with our plant, to at once obtain one; and, presuming such will be the case, before I give a brief detail of several known and desirable species, it will perhaps be as well to anticipate sundry inquiries that may suggest themselves to anyone who has carried out my presumption, such as—Where am I to plant it? how am I to plant it? and by what cultural processes shall I be likely to attain the most perfect results? and I may here add that these cultural directions are equally applicable to all the species to which I shall allude hereafter.

First, what is the best position? Not unfrequently do we find this plant occupying a somewhat unfortunate place in

Ferula communis.

the mixed herbaceous border, where, by the way, its vigorous growth usually enables it to hold its own amongst its neighbours; and possibly it is more frequently the sinner than the sinned against. At other times it is met with in the front of a shrubbery border, where, robbed of its food by its more vigorous neighbours, it usually drags out an existence in a manner neither creditable to itself nor satisfactory to its possessor. The proper place for it is on a slight grassy knoll in the centre of a nice sheltered bay or harbour indented into the coast line of shrubbery, which may be said to surround the verdant sea of grass to be met with in every well-designed and well-kept garden. Here, sheltered in some measure by the adjacent shrubbery—yet fully exposed to light on all sides—it will thrive luxuriantly, and be “a thing of beauty,” and, I had almost added, “a joy for ever;” but this reminds me that, roused into life early in spring (at the time I now write its verdant plumes are well unfurled), it has one failing—say rather, a natural sequence, that of losing its leaves about the month of August.

This is certainly a drawback to its otherwise adaptability to the conspicuous site I have given it; but, surely, a moment's consideration will suggest some plants to occupy its place.

Say a trio of the old, but much neglected Agapanthus, grown in large pots, which will form an admirable group, so arranged, as regards position, as to leave the crown of the Ferula clear.

As to the second supposed query—How am I to plant it? my reply is that a circle of, say, four feet in diameter should be marked out, and the first spit of natural soil dug out and set on one side; if the subsoil be gravel remove it to a depth of three feet, replace the top spit in the bottom of the hole, and add a good barrow-load of well-rotted manure; mix these up together, and then fill up with any good garden soil, leaving the circle well raised in the centre; if the subsoil be clay it need not be removed; but, after the surface soil is removed, let the manure be well dug in and incorporated with the clay below, returning the fresh surface soil, with some leaf-mould and sand mixed therewith. All the Ferulas are deep rooters and strong feeders, making in the course of years a root stock six or seven inches in diameter. In selecting your plant do not get an old stump; failing to obtain a moderately strong plant with a good tap root, choose a seedling, even though small, its progress will be more rapid and certain.

As to after management little need be said; a judicious selection of the plant, and careful planting, are the two stepping-stones to success; leave the rest to nature, and if the locality be dry, assist occasionally by a good supply of water, accompanied by a little liquid manure.

As to the species which are cultivated in our botanic gardens, I would enumerate the following:—

FERULA COMMUNIS.—Often named *F. Ferulago*, which may be looked upon as the typical plant of the first section—characterised by very finely divided supra-decompound leaves.

FERULA NEAPOLITANA.—Grows to a similar size, but has less compact foliage, and is slightly suffused with a glaucous hue, especially marked on the footstalks of the leaves.

FERULA CONSPICUA.—A Himalayan species, I believe, that has recently been introduced, and is said to be more of a giant than either of the foregoing; what its distinctive features are the immature state of my plants do not yet enable me to judge.

FERULA GLAUCA and the following belong to the second section, in which the divisions of the leaves are much larger, the alternate pinnae being almost lacinately lobed. In this species the leaf-surface, of the deepest green, shines as though it was varnished. The foot stalk and the back of the leaf, but more especially the flower stem, which rises to a height of eight feet, is covered with glaucous grey, whence its appropriate name; this is so distinct in general appearance that where two only are grown it should be one of them.

FERULA TINGITANA.—Closely allied to the former, is similar in appearance, but dwarfer in habit and more branching in the flower stem.

FERULA PERSICA.—Is even less divided in the foliage than either of the foregoing; it is a very scarce plant; and when I say that it is one of the sources of the Gum Assafotida, which is obtained as an exudation from the root, I think that the mention of the name in my brief enumeration of species will be sufficient.

JAS. C. NIVEN, *Hall Botanic Gardens.*

CITY VIOLETS.

FAIREST of Spring's fair children,
Babes of the flowery year,
Violets with dew-sprent eyes,
Deep-hued as midnight skies—
What is it ye do here?

To thousand, thousand workers
In labour's serr'd ranks,
Bright breezy thoughts ye bring
Of meadows white with spring,
Green crofts and sunny banks?

And therefore, Spring's fair children
Babes of the flowery year,
Violets with dew-sprent eyes,
Deep-hued as midnight skies—
Thrice-welcome are ye here.
—Chambers' Journal.

THE INDOOR GARDEN.

THE LONTAR PALM.
(*LIVISTONA SUBGLOBOSEA.*)

A most elegant Palm, worthy of being set in an isolated position, where its noble head of leaves can be seen to advantage. Its foliage resembles that of *L. chinensis*, but is compacter, and the plant itself is not quite so hardy as that kind. Its stem is corrugated and very regular in size. As will be seen, the head forms nearly a globe. The leaves

The Lontar Palm.

are used in Java, where it grows naturally, for basket-making, for thatching, and for hat-making. When they are intended for thatch, or for making fences, a use to which they are sometimes put, they are placed flat on the ground in layers, often with weight upon them to assist in flattening them. The thatch formed of them does not last, it is said, longer than two years, nor is it so handsome as that made from plaited cocoanut leaves. The selection of a few fine-looking palms such as this, giving them room so as to fully develop their beauty, is better by far, especially in private establishments, than having quantities crammed in a mass. This plant may be classed with those that will grow in the warm end of a conservatory. It acquires only a moderate size, and is easily cultivated.

J. CROUCHER.

THE CULTURE OF THE CYCLAMEN.

BY JOHN WIGGINS, ISLEWORTH.

CYCLAMENS are the most beautiful of all winter-flowering greenhouse plants. Their purity of colour and singularity of form make them universal favourites, and the early season at which they come into bloom invests them with additional interest. I have at present about twelve hundred established plants of Cyclamen, besides seedlings from last December's sowings. Of these, some eight hundred are about fifteen months old, the remaining four hundred being a year or two older. As a rule, I like the bloom which I obtain from plants of the first and second year best; but those of one or two years older produce flowers in greater abundance than younger plants. We have at Worton Cottage a lean-to house, measuring forty feet by twelve feet, which is at present filled with the different varieties of Persian Cyclamen, nearly all of which are in thirty-two sized pots, and each plant is bearing from one to two hundred flowers. I have among my plants, too, from twelve to sixteen distinct colours, such as pure white, crimson, carmine, lilac, salmon, and rose of distinct shades, &c. These and other colours in good Cyclamen should always be in themselves pure and unspotted, not "beautifully spotted and striped," as some describe plants at exhibitions, such spots and stripes being entirely the result of keeping the plants in cold, damp houses. To obviate such defects, maintain a continual, though slight artificial, heat in the house in which your Cyclamen are growing, and, at the same time, allow a free current of air, regulating it as to amount according to the state of the weather. This prevents that damp and stagnant atmosphere so much dreaded by all good Cyclamen-growers.

About the first of March we begin fertilizing the flowers, placing such plants as are retained for that purpose in a house apart from the others; and in furtherance of this end we select equal numbers of all the colours, omitting any possessing the least deficiency in size, form, or purity, and adopting flowers only that are perfectly uniform in shape, with broad blunt petals, each averaging about $1\frac{1}{2}$ inch in length, and having a well-defined base. The foliage, too, should be finely marked, and the plants should possess strong constitutions and quick-growing properties.

Some contend that Cyclamen may be successfully raised from seed, and bloomed in nine or ten months, in forty-eight sized pots; but this I feel certain cannot be done. To have good plants, the seed should be sown in December, in a temperature of 50°, and the young plants should be pricked off in spring into forty-eight sized pots, placing ten in each pot; and when big enough, they should be potted singly in small sixty-sized pots. When these are well filled with roots, which will be by the end of June, they should be potted into forty-eight sized pots, in which they will flower the following spring. After this shift they should be placed in a cool, sunless house, and well watered both at root and overhead. All stimulants, in the way of manure or guano-water, should be avoided, and nothing used except pure soft water, otherwise the flower-stalks become drawn and weak, and the strength of the plant expended in the production of foliage.

By this treatment, strong blooming plants may be obtained by March, period of fifteen months from the time of seed-sowing; and in less time than that I find it impossible to obtain well-flowered plants.

Some assert that they can grow good Cyclamen in cucumber beds, but judging from my own experience, such is impracticable. I always find it best to allow them some two months to germinate, then to keep them cool, and to bring them on gently. By this treatment they do not grow so quickly at top, but they form large bulbs underneath, and that much quicker than they otherwise would do, were they subjected to a higher temperature.

Much has been written respecting the compost best adapted for Cyclamen; some recommend a little peat, others a little decomposed cow manure, mixed with the soil employed for them, and this latter I have myself recommended, but I now find that its effects are more injurious than beneficial, inasmuch as it serves to breed worms and other insects that prove hurtful to the plants. Finding such to be the case, for the last four years I have used nothing but two-year-old rotted

turf and good leaf mould in equal quantities, with a liberal admixture of silver sand.

In potting, I keep the bulbs about three-fourths out of the soil, carefully avoiding the old plan of placing them under the surface, so that the flowers may come up clean, without danger of damping or rotting off.

As regards two-year-old bulbs, it is customary with many to dry them off in winter in by-places, keeping them without water until every root has become dead, consequently the leaves die. When it is wished to start them, they are repotted and watered, which is all but labour lost. Some of the bulbs push freely, but others break but feebly, drag out a miserable existence, and, after a time, die. I generally find it best to keep old plants in cold frames during their period of rest, and sufficiently damp to keep the roots in a healthy condition. Most of the plants shed their foliage, and those that do not, continue to grow throughout the season, and are the earliest to bloom.

Much has been said about growing Cyclamens close to the glass; but, where they form a part only of things that are benefited by such treatment, it is impossible to supply all with such a position; therefore, amateur growers of Cyclamens will be pleased to know that such is not absolutely necessary.

The stages in our houses are from six to eight feet from the glass, and I find no difference whatever between those grown on these and others grown nearer the glass. In the case of amateurs who generally grow Cyclamens along with miscellaneous plants, they should, however, select a stage as near the glass as possible, and in a cool or sunless part of the house.

Should the plants become infested with insects, I find it best to dip them two or three times in a mixture of soft soap and water, and when thus cleansed, they pass through their blooming season unharmed. By a free use of the syringe, I manage to keep them free from red spider and thrips.

As regards showing Cyclamens for competition: I object to the lateness of the season at which they are generally required. For instance, prizes were offered this year by the Royal Botanic and Royal Horticultural societies for them in the middle of April, when there is not a perfect plant of this charming family to be found. Two years ago I took the first prize at the Royal Horticultural Society's meeting for the best collection in April with an exhibition of two hundred plants, amongst which, on account of the lateness of the season, not one was perfect. January or February is the time to see Cyclamens in perfection. Let us therefore hope that managers of exhibitions may see reason to invite growers of this lovely winter and early spring flower to exhibit in the right season, and not when it is deficient in quality, and other things are plentiful.

FORCING MAY.

"It seems so odd to see May in February; but how charming!" was the remark of a lady on first seeing Paul's Scarlet Thorn in the beginning of last year. It forces admirably, and, as "G. S. W." says, everybody likes it. The foliage, too, is large and exquisite under glass. I have no doubt the commoner single ones will force equally well. All the doubles are as free as the scarlet. The double white was simply imitable from February till the end of March—one sheet of spotless white. The Mays make fine standards or pyramids, and as such impart quite a new charm to the conservatory, drawing-room, or staircase. Few plants are better adapted for the latter or bold landings, and they may be had any height. The pink is very delicate under glass. Next year I intend to force the single pink or scarlet, one of the most showy of all thorns. Unfortunately the double Mays are not so sweet as the single ones, that is the only drawback. The single flowers don't stand so long as the double, neither outdoors nor under glass.

Few plants can be of more service for cutting. Anyone with the least taste could extemporise a bouquet in a few moments with a stock of white and scarlet May, with the charming foliage of the latter; while for wreaths for the head they are imitable. In small vases or flat dishes, again, May is admirable, while branches of forced May would make the dinner-table glow with summer beauty in the depth of winter. I hope this will suffice to send all your readers a-Maying for forcing next November. Don't attempt it too early, nor push on too hard at first. The plants are sulky till the new year dawns, and they don't like higher excitement than a temperature of 60° at top and bottom.

D. T. FISHER.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Sarmienta repens.—Kindly say how I am to treat this singular climbing Chilean plant.—J. ELLIS.—[It requires cold greenhouse temperature (50°), and should be planted in a mixture of sphagnum, and peat.]

The Corn Marigold.—*Chrysanthemum segetum*, or *Corn Marigold*, a cornfield weed, probably of Mediterranean origin, but now common all over Europe, except the extreme north, is a showy and welcome novelty in our greenhouses in the early spring. At that season flowering plants of the same type are rare. If plants of it are lifted from the open ground in August, and placed under glass, they will flower freely, and, on account of their bright colour, prove good acquisitions to our stock of flowers at a period when other things are scarce.

Outside Shading for a Conservatory.—My landlord having just built me a lean-to, with a south-west aspect, but without any heating apparatus, I wish to put up a roller-blind, which will answer the double purpose of preventing scorching in summer and keeping out frost in winter. The house is twenty-four by twelve, and seven feet higher at the back than in front. What is the best material to get for the blind?

TROY.—We fear your landlord has only provided you a source of trouble, for if you expect to preserve tender plants without some special means of heating the house you will most certainly fail. A blind that would be a protection in winter would be a source of darkness in summer, and therefore unsatisfactory. The cheapest and most satisfactory thing that you can do will be to provide some means of heating the house, or otherwise devote it to Roses and other plants, such as will not be injured by frost. With Ferns, half-hardy American plants, Roses, and some choice half-hardy herbaceous things, you may make it very interesting.]

Mildewed Roses.—Two months back I had a small house made against a south wall, which was nearly covered by a Marshel Nell. I have several roses in pots and two planted out. They all started growing, are covered with buds, and until last week looked well; they were then attacked by mildew. I applied flour of sulphur; but it has not stopped it. The ground is high and well drained, and there is no soil at the back of the wall. I syringe about twice a week, admit plenty of air, and occasionally give weak manure water. The house cannot be heated. Can you give me any advice as to what I had better do?—AMATEUR.—[Mr. George Paul, to whom your question has been submitted, says:—With hold nearly all water; the syringing will supply almost sufficient moisture to the root, at least until the buds are swollen and commencing to change colour; as no pipes are in the house, and consequently no sulphurous steam can be produced, the foliage had better be dusted frequently and freely with powdered sulphur, washing it off the next morning with the syringe. The treatment seems correct, but on cold or windy days give air more sparingly, and in such a way as to avoid draughts.]

THE ARBORETUM.

JEFFREY'S BRITISH COLUMBIAN CONIFERS.

(Continued from page 461.)

SOILS FOR CONIFERS.

PICEAS generally succeed best when growing in deep heavy rich loam, or loam naturally mixed with peat, particularly many of the soft and blunt-leaved species, as *Picea nobilis*, *P. amabilis*, &c. While the generality of the prickly-leaved species, such as *Picea cephalonica*, *P. Pinsapo*, and the other allied species recently introduced, appear to be totally different plants when seen growing in a limestone district. At Graigo, in Forfarshire, *P. cephalonica* and *P. Pinsapo* far eclipse all other specimens planted in other places at the same time, except in those localities where limestone exists, a stratum on which they are accustomed to grow in their native country. I have no hesitation in saying that *Picea numidica*, *P. bifida*, and *P. Ciliicia* will grow much better on limestone than they now do in the loamy soils so well adapted for many other species of *Picea*. The finest tree of *Abies Menziesii* to be seen in Britain is the one in the Keillor Moon Pinetum in Perthshire. This tree is growing in deep peat soil, and, judging from its vigour, one would almost fancy it to be a distinct species from the plants of *A. Menziesii* generally seen growing under ordinary circumstances. The *Picea Pichta* is another tree totally changed in appearance when growing in soil of a peaty nature, where it assumes a remarkably pyramidal habit, while in ordinary loamy soils it is more or less bushy. The subject of soils is so very important that every scrap of information we can obtain will be serviceable to parties wishing to plant on the soils they possess, such kinds of trees as have already been proved to grow freely on similar soils. *Picea nobilis*, as I have said, is one of the trees which luxuriates in soil naturally composed of peat and loam. Although I have often tried the artificial mixing of peat and loam for this tree, also for several other species of conifers, they never assume the luxuriant appearance of those growing in the natural mixture.

MANURE FOR CONIFERS.

It may not be out of place to state, that many conifers, indeed I may say all, luxuriate in loam mixed with very old decayed horse manure. It throws a vigour into them almost equivalent to the natural peaty mixture. This is particularly noticeable with all the blunt-leaved Piceas, particularly the *Picea nobilis*, *P. amabilis*, *P. Lowii*, *P. magnifica*, &c. Many are much averse to the use of manures for conifers, and many are the questions put to me regarding the use of such stimulants. In a rough or fresh condition manure is by no means satisfactory, but totally different in a decomposed state, as is generally procured from old hot beds. While using manure it is necessary that it should be thoroughly mixed with loam before putting it round the roots of newly transplanted conifers; and for established ones, such as Araucarias, &c., the opening of a trench round the plants and filling it up with the mixture alluded to, will soon tell on the branches of the trees. I have never found guano or liquid manure equal to old decomposed horse manure, as a stimulant for conifers.

THE CYPRESS TRIBE.

Of this several interesting species were received from Jeffrey, and several names have to be corrected. *Libocedrus decurrens*, which may be ranked amongst his best introductions, was sent out under the name of *Thuja Craigiana*, and I find it is still cultivated under that name. This *Libocedrus* grows to the height of forty feet, with a stem nine feet in circumference. It must be grown in deep rich loam, in a somewhat sheltered situation, as it is very liable to be destroyed when fully exposed to the wind. It propagates freely by cuttings, and makes excellent plants, but it takes time to do so. Instead of forming roots at once, a rounded ball, about the size of a hazel-nut, is often produced at the extremity. If the cuttings are lifted, and portions of the outer skin of this small brown swelling cut off, roots will soon be given out from the edges of the cut extremities. Without this manipulation the cuttings will lie a long time in the ground in a fresh condition with no appearance of growing. This *Libocedrus* is likely to form a noble plant for the warmer districts of England and Ireland. One standing on the lawns in the Worcester nursery is eighteen feet high, with a stem two feet six inches in circumference at the base. The tallest specimen in the Edinburgh garden is fourteen feet, and the habit is quite that of the Irish yew. Grafted plants were sent from the Continent some years ago, and named *L. decurrens divaricata*. When first received, the branches had a peculiar diverging aspect, probably owing to their free-growing nature, on account of being grafted. Such plants are now quite as upright as any of the original seedlings. A *Thuja* raised from seed, and which has turned out to be the true *T. gigantea*, is another acquisition, first sent home by Jeffrey. When raised, the seedlings had much the appearance of *Thuja occidentalis*, and little attention for a time was paid to it. After a few years it began to assume an upright habit, and has gone rapidly increasing. The largest specimen is twenty feet high, and eighteen feet in circumference of branches. Numerous plants introduced by other collectors, under the name of *Thuja Lobbi*, *T. Menziesii*, and *T. Craigiana*, appear only to be varieties of *T. gigantea*, and although not as yet taking the rapid upright habit of this tree, they are very closely allied to it. This tall species of *Thuja* is perfectly hardy, and is readily increased by cuttings. From its peculiar upright habit, and standing the wind well, it will form a great acquisition to pleasure grounds; and as the timber of it is said to be good in quality, it may some day or other be grown for forest purposes. Although the habit of the plant is that of an upright-growing shrub, it will lose its lower branches, like the ordinary evergreen conifera, when growing close together. Another *Thuja* was raised from Jeffrey's seeds by Messrs. Backhouse, of York. This plant has a very distinct habit of growth, resembling in some respects the *Thuja gigantea*. It pushes up a strong loose branching leader, having all the side branches more or less pendent, the points of all turning upwards, and each of the lower ones assuming the appearance of a leader. This variety was sent out by Messrs. Backhouse under the name of *Thuja Craigiana*, as it happened to come up in the pot in which the *Libocedrus decurrens* seed (then called *T. Craigiana*) was sown. This peculiar variety is now extensively cultivated under the name of *T. Craigiana*. It is readily propagated by cuttings, and is easily distinguished in habit from all other species of *Thuja*. The largest plant growing here is fifteen feet high. A most interesting tree of this section I must not omit to record, is the *Cypressus Lawsoniana*. Although Jeffrey had not the credit of introducing the seed of this beautiful tree, he certainly deserves the credit of discovering it. I have stated that after the death of Jeffrey, all his effects that could be procured were sent home, including a large number of dried plants, amongst which were found several sheets of carefully dried specimens of what is now called *Cypressus Lawsoniana*, in excellent preservation. No seeds, however, were found. The specimens must have been collected fully

a twelvemonth before any seeds of the plant were sent to this country. The first importation of the seeds was in the autumn of 1855, and the plant was then named *Cypressus Lawsoniana*.

PINUSES.

Of the genus *Pinus*, Jeffrey was successful in introducing some new and interesting species. Perhaps the finest of all is *Pinus Jeffreyi*, which is stated to grow to the height of 150 feet, with stems twelve feet in circumference. In this country its habit of growth approaches that of *P. Laricio*, and, like it, the whorls of branches are proportionate to the age of the tree. This tree has a peculiar whitish green colour, and has been very extensively introduced into many nursery establishments, and ought to be planted in forest groups by some of our enthusiastic arboricultural proprietors. The largest specimen in the Botanic Garden is now nineteen feet high. It was introduced in 1853, and has seventeen whorls or branches. *P. Balfouriana* is another new and remarkable growing pine. In its native condition, it grows to the height of eighty feet with a stem nine feet in circumference. In this part of the country it seems inclined to dwarf. It retains a leader, and regular side branches. The leaves are arranged round the branches exactly like bottle brushes. Although introduced during 1852, the tree in the garden here, notwithstanding its symmetrical shape, is scarcely three feet in height. In peaty soil, and in a more southern climate, I have no hesitation in saying that the result would be different. Very few seedlings must have been raised, as few of the original plants are to be met with. Grafted ones only are to be had in nursery establishments. *Pinus flexilis* is another of Jeffrey's introductions. It is a diminutive tree, growing in its native habitat to the height of forty feet, with stems three feet in circumference. Being a mountain pine, it is inclined in this country to assume more the appearance of a large shrub than a tree. Like *P. Balfouriana*, it is very rare in collections, and, like it, few seed-must have been raised. Grafted plants under this name are to be had in nursery establishments, some of them however totally different from the original *P. flexilis* sent home by Jeffrey. *Pinus Murrayana* is another of Jeffrey's introductions. Of this tree the seed must have been mixed, as two distinct varieties came up—the one having an upright growth and of a beautiful light green colour; the other of a scrubby habit and dark green, very different from what Jeffrey describes it, viz., a conical growing tree. One of the finest specimens of the upright variety that I have seen, is growing at Borthwick Hall, near Edinburgh, the seat of Charles Lawson, Esq. Jeffrey also sent home seeds which he called *Pinus tuberculata*. This is a very interesting tree, having a large globular head of a light green colour, and very hardy. In this respect it is different from the plants previously cultivated under that name, and originally sent out by a London nurseryman. These plants had more of a tree growth, with thicker leaves of a dark green colour. The latter were entirely destroyed here during the winter of 1860-61, while Jeffrey's stood uninjured on the same piece of ground. Besides the foregoing species of *Pinus*, Jeffrey also sent home seeds and cones of several kinds previously introduced, such as *P. Lambertia*, *P. monticola*, *P. Benthamiana*, *P. ponderosa*, *P. Sabina*, and *P. Coulteri*.

Jeffrey's seeds were divided into 281 lots, and were sent all over Europe, and even to America. Other species of conifers than those here noticed may have been raised, the owners probably imagining that they must have been grown by other parties as well as themselves.

JAMES McNAB.

THE DWARF ALMOND.

(AMYGDALUS NANA.)

Nobody who knows *Amygdalus nana* will contest the fact that it is one of the most beautiful of early-flowering shrubs. How comes it, then, that it is not to be found in every garden? The fact is the more surprising as it thrives in almost any soil and situation, and that its small size permits it to find a place anywhere—in the smallest garden as well as in the most extensive. It forms a bush, which in March and April is covered with flowers, which vary in colour from pale pink to a deep red. Sometimes, but rarely, there springs from seed a variety bearing white flowers. Of this we have sown the stones, but they have always reproduced a plant with red flowers. Others may, however, have had a different result. In *Amygdalus nana* the colour is deeper than in any of the other sorts; but its chief merit consists in the long time in which it continues in flower. It is a healthy, strong shrub, with medium-sized deep red flowers. It is increased by means of seeds or suckers. The former should be sown in the autumn in which they are gathered, and the young plants will appear the following spring; in the autumn, such plants as are strong enough can be put in their places. If this cannot be done before winter, it should be done in spring, before the plant commences to shoot up. Varieties which

it may be desirable to keep, ought to be multiplied by dividing the root, by separating the suckers, or by means of root buds. It is not only as an ornamental plant for private gardens that we recommend the cultivation of this dwarf almond, but as a market plant in pots.

There are no varieties of *Amygdalus nana* that have double flowers, red and white, as is mentioned in some books. Such guides are apt to mislead, because not only have we never seen the varieties of the dwarf almond with double flowers, but all our colleagues to whom we have spoken have affirmed that they have never existed except on paper.—*Revue Horticole.*

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE HEART-LEAVED HAWTHORN (CRATAEGUS CORDATA).

This forms a handsome, vigorous, close-headed, small tree, from ten to twenty feet high, which flowers very late in the season, and retains the greater portion of its fine dark glossy leaves, and numerous clusters of small coral-like fruit on it till mid-winter, and in mild seasons may be termed sub-evergreen. It is a native of North America, where it is found plentifully in hedges and rocky places, from Canada to Virginia. It was first introduced in 1738.

The leaves are alternate, ovate pointed, cordate at the base, irregularly lobed, quite smooth, of a deep shining green above, but pale beneath, and on long slender footstalks, and, according to the age and vigour of the plant, from one and a

Group of Leaves of *Crataegus cordata*.—Natural size, 3 to 3½ inches, including Footstalk.

half to three and a half inches long, and from one to two and a half inches broad, with the lobes deeply angled, largest towards the base, and irregularly and coarsely toothed along the margins. The branches are slender, deep brown, and sometimes furnished with a few straight spines, frequently more than an inch in length. The flowers are small, white, and produced in great abundance in the end of May and beginning of June, in loose, terminal, many-flowered corymbs; fruit, very small, bright red, and with two or more hard bony seeds in each.

This is a very distinct and desirable kind, which is well suited for small gardens, or for planting singly on the lawn, on account of its retaining its leaves and fruit until very late in the season.

It has the following synonyms:—*Crataegus populifolia* and *acerifolia*.

THE BLACK CYTISUS (CYTISUS NIGRICANS).

This forms a small upright deciduous shrub, from three to four feet high, in any good garden soil, and produces flowers in great profusion in June and July, and sometimes again in the autumn; but when grafted standard high on the Laburnum, it forms an elegant, compact, round head, of which nothing of its kind can be more beautiful in summer, when loaded with its long spikes of flowers, which are so brilliant that the eye is at once arrested by them. It is a native of

Bohemia and Piedmont; it is perfectly hardy, and is easily increased either from seed, or by grafting on the common Laburnum. It was first introduced in 1730. The leaves are trifoliate, stalked, and deciduous, with the leaflets elliptic, and clothed with closely pressed soft hairs beneath. The branches are round, slender, twiggish, and downy. The flowers are pea-shaped, bright golden yellow, and produced in elongated, terminal, erect, simple spikes or racemes, containing from twenty to thirty flowers each. The calyx is downy and bractless; the pods are many-seeded, downy, and black when ripe. The specific name "nigricans" was given to this kind on account of its turning black in drying.

NOTES ON HARDY TREES AND SHRUBS.

Trees for Churchyards.—What are the best trees for planting in a churchyard? I do not wish the most desirable kinds as regards habit, but those that strike their roots downwards rather than horizontally.—F. G. H.—[Plant planes, oaks, chestnut (both kinds), sycamores, and to some extent, limes. The best deciduous trees are planes and chestnuts, and the best evergreens are yew and holly.]

The Largest Araucarias in the British Isles.—Can you kindly state where I can find the finest specimens of Araucaria in Britain?—L. U.—[The two finest we have seen are those at Woodstock, in Ireland, and at Dromore. The Dromore specimen was on January 23, 1871, fifty-one feet high, and five feet six inches round at three feet from the ground, the spread of the branches being twenty-eight feet in diameter. It is taller than the Woodstock tree, but is not so large in the bore.]

Large Copper Beeches.—I have two copper beeches I am inclined to be proud of. One is 50 feet 7 inches high, 10 feet 1 inch in girth at 3 feet from the ground, and 243 feet in circumference of branches. The other is a little taller, but not so thick in the stem. The largest tree I believe to be fully 200 years old. I should be glad if any of your numerous correspondents would state if they know of any larger specimens.—L.

Prairie Planting.—Senator Hitchcock's Bill "to encourage the growth of timber on the Western Prairies," proposes a gift of a quarter-section of the public lands to any person "who shall plant, protect, and keep in a healthy, growing condition, for five years," not less than 120 acres of timber; provided that no more than one quarter in any section shall be so acquired. Moreover, any person taking a quarter-section under the Homestead Act shall obtain a patent therefor (without waiting five years for it) on due proof that he has planted not less than ten acres with timber, and has had the same growing not less than two years.

The Magnolia Holly (*Ilex latifolia*).—We have just seen a specimen of this at Mr. Coombe's, Cobham Park, which, a little distance off, looked exactly like one of the pyramidal specimens of *Magnolia grandiflora* that one sees in the south-west of France, and occasionally in choice gardens about Paris. It is one of the handsomest evergreens we have ever seen, and as unlike the common type of holly as any evergreen can be—the leaves being from four and a half to six inches long, not measuring the stalk, and from two to three inches broad. The specimen is one of many fine trees planted at Cobham Park by Mr. Stevenson, the able gardener there.

GERALD MASSEY ON "SPRING."

WHEN Spring herself is here, in vain we look
To find her likeness pictured in a Book!
For Memory can only catch a gleam
Of all the glory trembling through her dream,
As vainly, year by year, the Poets try
To arrest the Eternal as it glimmers by
In evanescent visibility.
We feel so much more than we ever see :
See so much more than we can sing or say.
Spring comes, with all her young things all at play,
And breathes her freshness through this life of mine,
Freshness divinely fresh from the Divine !
The spirit of life ascends in flame and flush,
Thro' every blade and blossom, briar and bush.
As winter fires die out, so fades all thought
Of Spring before her miracle newly wrought.
The little slip of Spring that wavers by
In smiling shape of the first Butterfly—
The earliest Snowdrop, youngest Violet,
Wear all the wonder of the first Spring yet.
The Cuckoo comes each year with spell to start
The blithe glad leap of Childhood in the heart:
As fresh to-day the springing of the Lark
As when he gushes up heavenward from the Ark.
Wood-hyacinths quivering in a breath of blue,
The night-bird's old sweet song, are always new.
Springs fleet and fade away, but Spring dies never !
The rainbows pass ; the Rainbow lives for ever.

—Good Words.

NATURE'S TREE-GROUPING.

PRANKS of nature are nearly always pleasing, and even symmetrical, in the highest sense of the term; but the pranks of art, except in the rare instance of being the aberrations of real genius, as in the case of Turner, for instance, are nearly always detestable failures. But it is more especially in horticulture, whether landscape gardening or flower gardening, that the eccentricities of so-called art become most offensive to the judgment of such as have trained their taste upon the teachings, ever new and ever charming, of the varying lines and masses and endless combinations of nature—lines and forms which, where least expected, are continually greeting the cultured eye with some kind of pleasant surprise, forming accidental juxtapositions of objects, such as the premeditated arrangements of art, can never match in the grace and freshness of the effect—for art is continually

but his knows how to seize, and translate into art, with such unerring truthfulness.

The little sketch that has suggested these remarks is but a mere fragment—an utterly insignificant scrap—a stray shred of beauty from an ordinary lane and ditch, and yet it would be difficult, even in the most carefully planted "grounds," where art has done its utmost, and expense and skill been freely lavished, to find a little *more* more carelessly charming than this half-dozen yards of a deep-rutted lane; a spot seldom, if ever, seen except by the unappreciating eyes of the waggoner or ploughman, wending their way to the long day's drudgery, without a thought about the grouping of the trees before them—or, perhaps, without even noticing the glorious carols of the lark overhead, who sings to them unheard.

Grouping in gardens is almost entirely neglected. Although the writer lives in the midst of gardens, he could not find a group so pretty as this roadside one; and, of course, this does not arise from lack of material, but simply from want of taste and knowledge. We have ample materials in our gardens for forming groups in infinite variety and of the most charming character.

H. N. H.

Tree Grouping—A Sketch from Nature.

repeating itself; nature never. In the accompanying sketch, three elms, nearly in a row, two of them rising from a dark and tufty thicket in the corner of a field, and one from a sparse tangle of low brushwood outside, form, by some mysterious sleight-of-hand of nature, a ready-made picture—one for the earnest student of true effect to study and to admire; and then, as though it were done expressly for the purpose of completing the picturesque combination of forms and lines, come three pollarded willows, each leaning its gnarled and knotted trunk exactly the right way to balance and give variety to nature's improvised picture—a picture which is what in art would be called a complete composition, though it consists but of two self-sown elms in the hedge at the waste corner of a field, another on a low ridge at the side of a cart track, and three pollarded willows on the rough bank of a shallow ditch. This little picture of nature's improvisation is one for even a Birket Forster to study—such a one as that truest delineator of English landscapes must have often lingered over in delicious pencil-pondering, while teaching his hand its fascinating power to detect the secrets of all the quiet sweeteness and shaded beauty of our country lanes—which no hand

The India-rubber Supply.—The fear lest the yield of caoutchouc by the Brazilian forests should fail, consequent upon the destruction of the rubber-trees in the process of collecting the juice; and the neglect of the natives to plant others, is to a certain extent confirmed by our Consul at Para, who, writing on the condition of the industrial classes in Brazil, describes the collecting of rubber as one of the principal occupations of the natives. "An expert and steady Tapuzo, the class chiefly employed in extracting rubber, will collect about eight pounds English per day, which on an average is worth eight neilreis, or about 13s. 4d., i.e., ls. 8d. per pound. In a good rubber district men are known to extract even an 'andba' of rubber, or thirty-two pounds English per day; but about eight pounds is the average collection per man. The method of extracting the milk from the rubber-tree is primitive, and still more primitive and rude is the manner of smoking or curing the rubber milk, over smoke issuing from a funnel, under which is fixed an oily nut (fruits of Attalea and Cocos). Already the more accessible rubber districts are becoming very much exhausted, and give a much less yield than in former years, yet the rubber-bearing country is so vast that the constantly newly-discovered sources more than supply the deficiency occasioned by the exhaustion of the old. The people are as yet unimbued with the necessity of planting the rubber-tree or caring for its growth."

THE PROPAGATOR.

ON PURE HYBRIDIZATION, OR CROSSING DISTINCT SPECIES OF PLANTS.

BY ISAAC ANDERSON-HENRY, ESQ., F.L.S.

(Continued from page 481.)

APPEARANCES IF THE CROSS HAS SUCCEEDED.

We shall suppose the cross now performed. Your next anxiety will naturally be to find out whether it has taken. Almost all experimenters have noticed that soon—I would say from six to ten days—an alteration is observed on the stigma and style. You will find the viscid matter on the former dried up, while the latter has begun to shrivel. You will naturally conclude that it is all right, and that the fertilizing pollen has now passed down into the ovary, and in some cases you may be right. But these appearances are deceptive, especially if you find the style maintain an erect position. And singularly, as I now write, I find, on glancing at the *Gardeners' Chronicle* of the 19th October, 1867, that this state of matters had been observed last summer by the learned editor of that publication and described in his leading article of that day. He there observes, "We have ourselves, in following some experiments on cross-breeding this season, noticed that the stigma becomes changed—withered, almost immediately after contact with the pollen, even if no perfect seeds be produced." Now that gentleman is quite right; but I did not note the withering effect to be just so immediate as he had observed it, though it might have been so in the *Epilobium* tribe, to which his experiments refer. Another effect I particularly noted last summer was that, in attempting to cross an Indian azalea with a rhododendron (which, however, in that instance failed), not only did the stigma and style decay, but the divisions of the calyx took on a purplish tint, and a honeyed secretion continued long to exude from the disc. Another still more misleading condition often arises, as is noticed in the same leading article of the *Chronicle*: "The ovary will swell, the fruit will set, in some cases without any contact with the pollen at all, though of course no embryo is produced." Wichura has noticed the like result, and the following degrees of failure noted by him have so often occurred in my own experience, that I cannot do better than cite them in his own words, from the Rev. Mr. Berkeley's translation already alluded to, which I only alter according to my own experience:—1st. The organs submitted to hybridization (the stigma and style) soon wither, but do not in all cases soon fall off. 2nd. The ovaries swell and ripen, but do not contain a trace of seed. 3rd. The ovaries may seem filled (I say may seem partially filled), having in some instances the small protuberant swelling outside as if seeds were within, and yet no seed be there. 4th. Seeds are present, but small, languid, and incapable of germination. 5th. Seeds apparently perfectly developed which do not germinate. 6th. Seeds which germinate, but the young plants are weak, and wither in a short time, dying off often-times after developing the seed-leaves. I have had all these conditions and results amply illustrated; and of the second of these results I had, last summer, mortifying proofs in a muling operation I tried, by fertilizing a flower of the new *Arabis blepharophylla* with my still newer *Draba violacea*. The cross, to all appearance, had taken; the seed-vessel swelled better than the others where no experiment was made, and while the valves of the siliques of these last opened and showed no trace of seed in them, the siliques of the former remained closed, showing by outward development that two seeds were certainly within. But I found on opening the ripe seed vessels that there was no perfect seed in the interior, but only an abortive production. While Wichura's accuracy in the above degrees of failure is consistent with what I have myself had ample experience of, I cannot, from like experience, endorse the views he has formed on some of his successful results. At page 72 of the above article in the *Journal of the Royal Horticultural Society*, Mr. Berkeley, commenting on Wichura's paper, observes:—"Gärtner, indeed, supposes that in genera which are rich in species, there are some which have a prepotent influence when hybridizing, so that in some hybrids the type either of the male or female prevails. Amongst the various hybrid willows, though the genus is so rich in species and so prone to hybridizing, Wichura has never seen a prepotent type, and doubts Gärtner's statement, especially as he makes it in very qualified terms." Mr. Berkeley very judiciously remarks that it is not very easy to determine, "by examination of types, whether a hybrid is more like the mother or father—the perfect distinction is subject in many cases to great difficulties, since very much depends on the subjective view of the observation; for, in consequence of the frequent intermelting of both characters, the one observer finds in a hybrid the maternal type, while another thinks the paternal type prevalent." By which I regard Mr. Berkeley as very modestly dissenting from

his author. And further on, at page 78 of the same Journal, Wichura speaks out still more absolutely. "When both parents," says he, "belong to the same species, we cannot tell what part the male and female parent take respectively in the formation of the progeny. But dissimilar factors are united in hybrids, and an intermediate form is the consequence. The products which arise from reciprocal crossing in plants, unlike those which are formed amongst animals, are perfectly alike." I regret to differ from so great an authority as Wichura, and must venture to demur to the doctrine in more decided terms than Mr. Berkeley does. I have had so many instances of hybrids taking sometimes to one side and sometimes to another—but most frequently to that of the mother—that to those who like myself, have made experiments with many genera, it would be needless to give instances. The converse is the rarer case—*i. e.*, where the paternal type comes out most marked. Yet I remember one eminent instance of a seedling *Veronica*, from the batch of seedlings from which I obtained *V. Andersonii* (*V. salicifolia*, *V. speciosa*), being so like the male parent *V. speciosa*, that I presented it to a friend in the belief it was purely and simply the latter species; but when it bloomed, it showed, by the longer spike and lighter and brighter colour of the flowers, and by their being a bright crimson instead of very deep purple, which is the colour of the flower of the *V. speciosa*, that the blood of the *V. salicifolia* was there. I can well understand that, as respects the family of willows, from their being so attractive to bees, and from their being naturally so prone to intermix (insomuch that few can tell what is a species and what is a hybrid), Wichura has not much overstated the fact, and that a distinct intermediate form may generally be reckoned on.

I must dissent still more strongly from what Wichura lays down in continuation of the above passage at page 78, as to reciprocal crossings. "The products," he says, "which arise from reciprocal crossing in plants, unlike those which are formed amongst animals, are perfectly alike." It is of no consequence which is the male and which the female parent. It is, therefore, a mathematical necessity that the pollen-cells must have just the same part in the act of generation as the ovules." And, based mainly on this doctrine, he follows up and amplifies it in a series of aphorisms which, he admits, are to be "considered conjectural, and require to be submitted to proof," an admission for which he is to be commended, and all the more if he submitted to the like test the dogma on which they mainly rest. It humbly appears to me that his statement had been suggested from his experience among the Salices—of all plants the most mongrel in a state of nature. Now, in all this, Wichura appears to me to imply that if a distinct intermediate may be formed, and is formed, by crossing A on B, so may an exactly similar intermediate be reciprocated by crossing B on A. And M. Naudin, in his experiments among the Daturas, enunciates the same belief, and holds "that there is not a sensible difference between reciprocal hybrids of two species." That distinguished observer, like Wichura, seems to have confined his experiments to herbaceous or soft-wooded plants. But, from a long and large experience among both hard and soft woodied plants, I demur, 1st, to the capability of the parents being in all cases made subject to such reciprocity; and, 2nd, to the statement where such reciprocity does hold, that the progeny are perfectly alike, whether A or B supply the pollen.

In my various crossings I have experimented on many hard as well as soft woodied genera—in particular, I would here instance among the former the species of rhododendron. In these I have again and again been baffled to reciprocate a cross which on one side was comparatively easy to be effected. When the lovely and fragrant *Rhododendron Edgeworthii* first bloomed in this country, all were eager to see its beauty and perfume transfused into dwarfier and harder forms. Some tried the cross by making *R. Edgeworthii* the female or seed-bearer, others by making it the male. I tried it in both ways, but all my efforts failed where I attempted the cross on the *R. Edgeworthii*. But while it would not be brought to bear hybrid seed, I had no great difficulty in effecting a cross from its pollen on *R. ciliatum*, another of Dr. Hooker's beautiful Sikkim species having all the desirable requisites of hardihood, dwarf habit, and free-flowering tendency; and, singularly, just as I had obtained and sent off blooms of this brood to lay before the committee of the Horticultural Society of London, Messrs. Veitch, of Chelsea, anticipated me in having a plant of this identical cross first exhibited before that committee, which is now well-known and generally cultivated under the name of "*Rhododendron Princess Alice*." Now, neither I nor anyone who ever tried it, so far as I know, ever effected the *inverse* cross of *R. ciliatum* on *R. Edgeworthii*; and if they did, the progeny would long ere now have appeared in nursery catalogues. There is yet one other instance I may notice as an illustration of what I am now contending for. In my former paper I noticed, as an exception to a

rule I had found almost general—viz., that European had great aversion to cross with Asiatic species—that I had, notwithstanding, effected such a hybrid by crossing *R. eleagnoides* (another of Dr. Hooker's acquisitions, a tiny Sikkim species) on the European *R. hirsutum*, and of having sent the survivor of the two plants which came of it to Kew, of which, by the way, Dr. Hooker writes me, that it dwindled away and died after being a few years in their hands; but by no possible means could I invert that cross, or get that same very interesting tiny yellow-flowered species, *R. eleagnoides* (a form of *R. lepidotum*), to submit to a cross from any species whatever.

I shall now advert to the second point which Wichura lays down as a fact—viz., that the progeny of reciprocal crossing, whether it is A on B or B on A, are precisely alike. While my past experience goes with what I observed last summer, it may perhaps suffice to give the latest instance. Having, through the kindness of Dr. Hooker, obtained seeds of a beautiful new Californian *Arabis* (*A. blepharophylla*) with large fine rose-tinted flowers, I felt desirous to infuse that colour into some of the other kinds I possessed. After trying it on several, especially on *A. alpina*, in vain, I at last effected a cross—a reciprocal cross—between it and A. Soyeri, a white-flowered species from the Pyrenees, something like *A. alpina*, but with glabrous foliage. Of the cross A. Soyeri on *A. blepharophylla* I have raised six plants, the product of two very largely developed seed-pods. These plants are alive and healthy, and promise an improved vigour over either parent. That the cross was sure, I had the best proof, from there being no seeds in the normal pods of the seed-bearer. Of the inverse cross from one weakly seed-pod I raised one plant, which, after maintaining a sickly existence for some two months or so, has died off. But while this last cross was equally certain as the others, like it, the plant had more of the mother than the father in it. In fact, I have often found the maternal type most marked in hybrid progeny. I have various crosses effected between distinct species of rhododendron, where, while the male manifests his presence, the female type prevails. I have it in R. Jenkensi crossed by R. Edgeworthii, R. caucasicum by R. cinnamomeum, and the hybrid from this latter cross crossed again with R. Edgeworthii, and especially the Sikkim species *R. virgatum* crossed with another of my hybrids, *R. ciliatum* by R. Edgeworthii—all having more the foliage and the aspect of the mother than the father.

I have another hybrid of the same *R. virgatum*, the female parent crossed, I believe, by *Rhodothamnus chamaecistus*, a tiny procumbent plant of three inches, but all set with flower buds—not, as in the male parent, at the tips of the shoots, but, as in the female, at the axils of the leaves. I have stated my belief that the *Rhodothamnus* is the male parent, but I cannot do so confidently, from the tallies having got into confusion—the specimens being planted out. But as some plants were obtained from that cross, and as this is the smallest, I regard it as likeliest to be the true progeny; and the cross being an extreme one—a mule, in fact, it is open to question. But as I have this season effected still more extreme—certainly more unlikely—crosses in that family, where there could be no miscarriage, you may, I think, take it as true in the meantime. I could overwhelm you with proof. Darwin, at page 333 of the last edition of his "Origin of Species," has observed the above tendency. "When two species," he says, "are crossed, one has sometimes a prepotent power of impressing its likeness on the hybrid; and so I believe it to be with varieties of plants."

Naturalists of the highest note—Gärtner, Kölreuter, Naudin, and Wichura—are far from being at one on the subject of variability, as Darwin has shown, especially as relates to crosses, 1st, between species and species; 2nd, between species and varieties; and 3rd, between mongrel offspring. But this is a complex subject, and when such high authorities are not at one, and Darwin admits that he cannot reconcile them, it is manifest that the case is still open to further probation. In dealing with the views of Gärtner, to whose testimony he deservedly accords great value (page 331), Darwin says that Gärtner, whose strong wish "it was to draw a distinct line between species and varieties, could find very few, and, as it seems to me, quite unimportant, differences between the so-called hybrid offspring of species and the so-called mongrel offspring of varieties. And, on the other hand, they agree most closely in many important respects. The most important distinction is, that in the first generation mongrels are more variable than hybrids; but Gärtner admits that hybrids from species which have long been cultivated are often variable in the first generation; and I have myself seen striking instances of this fact. Gärtner further admits that hybrids between very closely allied species are more variable than those from very distinct species, and this shows that the difference in the degree of variability graduates away. When mongrels and the more fertile hybrids are propagated for several generations, an extreme amount of variability in their offspring is

notorious; but some few cases, both of hybrids and mongrels, long retaining uniformity of character could be given. The variability, however, in the successive generations of mongrels is, perhaps, greater than in hybrids." So reservably does Darwin deal with a subject on which the opinions of others could be brought to bear; but as they are not all concurrent, and not unfrequently conflicting (which they may well be from the various subjects experimented on) he has said, with commendable moderation, all that can be said on the subject.

(To be continued.)

RE-GRAFTING PEARS.

THERE has been a good deal of unsettlement in past years in the list of pears regarded as worthy of general cultivation, and some that were highly lauded at first have proved of little value. This may be partly owing to a difference in soil and climate, as a fruit which succeeds well at one place is sometimes worthless at another. A few that gave high promise are found to be liable to mildew and cracking, and they must give place to better varieties. Nearly every man who has now an orchard of pears, would like to change some of his trees for other sorts. Fortunately, the operation of re-grafting is remarkably simple and easy with pear trees, and by the insertion of twenty grafts more or less, on each tree, properly distributed, new and perfect bearing head may be obtained in two or three years. Instead, therefore, of digging up and throwing out such trees as do not bear good pears, and leaving undesirable vacancies where they stood, they are readily changed to the very best. The first thing to do, after having secured the grafts, is to prepare the trees for re-grafting, by trimming the branches of most of their fruiting spurs, and cutting out any not wanted where they happen to be too thick. Then cut them off so as to form a regular pyramid, by leaving the bottom ones longest, and gradually tapering to the top. If the branches are small, they may be whip grafted, but usually they will be much too large and will require cleft grafting. We have seen large numbers of dwarf pear trees which were eight or nine years old when worked over, that in three years were as perfect trees and as abundant bearers as those which had not been thus changed. An active grafter will work over twenty or thirty such trees in a day, setting a dozen or twenty grafts on each.—*Cultivator.*

ROOT GRAFTING APPLES.

APPLES may be grafted successfully as follows: Seedlings grown in rich loamy soil, either one or two years old are lifted when there is no frost in autumn, cleaned and stored in sand, in a cellar, and not so damp as to be liable to mildew. The scions should consist of the previous summer's growth. Cut them into four or five inch pieces, each having from four to six good, sound, perfectly formed buds. The lower end of each of these pieces should be cut, as in ordinary grafting, and the roots cut about four inches long. The best piece is the one at the collar. At the upper end of each piece of root make a vertical cut upwards, forming a flat surface into which, from the upper end, cut a slit forming a tongue, which will fit a corresponding slit previously made in the scion. With a little practice, anyone can make the bark of the scion and that of the root on the ends where the flat surfaces are formed fit so closely that the sap of the one can flow into the other and produce the granulation or healing process without failure. The fitting can be done so that the union will be quite strong; but to make the matter doubly sure, the best way is to tie with a string which has been saturated with hot grafting wax. Pears, plums, and cherries, may be grafted in this way, only the root should be left longer, and only the collar cut used. The next important matter is the proper care of the grafts. I have been most successful by packing them upright in a shallow box, say one inch deeper than the grafts are long, after dipping one-half of the roots into a puddle made of clay and fresh cow dung, and filling up with sand, leaving about an inch of the scion above the surface. The boxes of grafts should then be stored in a dark part of the cellar until frost is over and the ground is quite ready to receive them.—*American Paper.*

MINIATURE BERRY-BEARING AUCUBAS.

A FEW days since, when visiting the plantations of the Fleuriste de la Ville de Paris, amongst many other interesting matters, we observed a method employed by M. Loury, head propagator of that establishment, for obtaining Aucubas laden with fruit in very small pots. This is effected by cutting from strong plants branches bearing berries which have arrived at their full size, and striking them as cuttings. Treated in this way in November and December, and even in January, in about six weeks one can have miniature

plants well rooted, laden with fruit, and apparently several years old. We should not be surprised if this mode of propagation is soon practised on a large scale, and becomes the foundation of a very important branch of commerce.—*Révue Horticole.*

THE ART OF GRAFTING.

(Continued from page 467.)

GRAFTING WITH DETACHED SCIONS.—GENERAL DIRECTIONS.—The stock is a perfect plant, or almost so, for we shall sometimes use a branch cutting or a piece of a root. It is grown either where it is to remain or in the nursery, or else it may be grown in a pot in order to be grafted under glass with the air partially excluded. Perfect stocks are usually grafted where they are intended to remain; sometimes in the case of graftings made during the repose of the sap, the stocks are taken up in order to graft them, and laid in a trench or under a shed. The scion is a branch or part of a branch, bearing at least one eye, and from two to six inches in length. The shorter scions are used in the case of kinds with closely set buds or expensive varieties. In a cold climate they must be of a greater length. The scions may be taken from the parent plant, when the sap has gone to rest, for spring graftings; they should be kept then in the shade of a building or tree, with the ends buried in fine sand. If they are not required to be used until the sap begins to flow they should be kept in a cool cellar entirely covered with sand. Evergreen scions should not be detached from the parent tree until immediately before they are grafted, and the leaves should be left on them. Deciduous kinds grafted in summer should be cut from the parent within twenty-four hours before grafting, and their leaves at once cut off. It will matter little to the success of the operation whether the upper bud of the scion be a terminal or a lateral one. A shoot if too long may be shortened, and, if required, may furnish several scions. In order to facilitate the joining and cohesion of the two parts, the scion is more or less cut at the base in a sloping direction or splice cut. It should also be so placed on the stock that a bud of the latter may be on a level with the graft, either opposite to it or on one side, in order to draw the sap, and thereby promote the cohesion of the parts. The different sections of branch grafting are side-grafting, crown-grafting, grafting *de précision*, cleft-grafting, English method, and mixed grafting.

SECTION I.

SIDE-GRAFTING.—The term side-grafting might be applied to a vast number of processes of grafting in which the head of the stock is not cut away. But we have limited the term to those cases in which the scion is inserted into the side of the stem, or on a branch of the stock, either between the bark and the albumen, or into the albumen itself, the bark in no case being removed.

SIDE-GRAFTING UNDER THE BARK.—GENERAL DIRECTIONS.—When it is desired to graft a branch on the side of a stem and under the bark, the stock must be in a state of vegetation, and the operation is performed either in April or May, at the flow of the sap, when it is said to be done with a shooting bud; or from July to September, when it is termed a graft with a dormant bud. In the first case (with a shooting bud), we use scions of the previous year, which have been laid in at the north side of a wall or in a cellar, to preserve their vitality, and the sap being in motion at the time they are used, the graft will develop itself in the course of the same year. In the second case (with a dormant bud), in which the graft will not develop itself until the year following, scions of the current year are used, cut on the day of grafting. If they are deciduous kinds, the leaves are cut off. We have said before, that scions of evergreens should not be cut till the last moment, and are not to be stripped of their leaves. In both of these methods the tops of branches with a terminal bud form excellent scions. We know two systems of side-grafting under the bark, one in which the scion is a piece of a branch pure and simple; in the other, it is a branch cut from the parent, with a heel or strip attached to the base.—*Charles Ballet's "l'Art de Greffer."*

(To be continued.)

THE FRUIT GARDEN.

GLASS AND IRON COPING FOR FRUIT WALLS.

I NEVER before registered such a day as Sunday last, April 21st, with the pears, plums, cherries, gooseberries, currants, and raspberries in full flower, and the snow quite covering the flowers and foliage for a few hours. The morning commenced dull, with a frosty north-east breeze, and soft snow began falling at nine a.m., which continued for four hours, covering the ground to the depth of an inch. Heavy rain afterwards set in, and when it cleared up in the afternoon, the melted snow and rain registered one inch and twenty-one parts by the rain gauge. The effect of such weather on the blossoms of fruit trees must be very injurious, and shows that in our fickle climate means of protection must be taken by all gardeners so as to have a supply of wall fruit every year. The glass and iron coping to fruit walls, of which you gave illustrations last week (p. 476), seems to me to be an excellent mode of answering such a purpose, and with the coping converted into a regular fruit house, it must be still more effectual. A south wall covered with such a coping would be just the situation in which to set good crops of apricots; and then, by covering them with the glass lights in the summer, fruit could be had of the finest flavour and size. The apricot, it is well known, will not bear forcing much, or set its fruit well, unless it has plenty of dry spring air wafting amongst its blossoms in February and March. The permanent glass erection manufactured by the same company, named their expanding fruit house, is evidently another excellent plan for preserving the most choice and valuable of our wall fruit. Having had the management of a similar erection for some time, I can speak from experience of the many uses to which such cases can be put, such as growing salads in winter and hardening off bedding plants in the spring, as well as growing the finest peaches, nectarines, plums, and cherries in the summer.

Welbeck, Worksop, Notts.

WILLIAM TILLERY.

ROYAL HORTICULTURAL SOCIETY'S FRUIT COMMITTEE.

WHEN this was first formed, I, among others, thought we should gain some practical information from it; but, except to the few who have 'opportunities' of attending its meetings, it is a blank. I remember committees being formed all over the country for the purpose of naming fruits, and obtaining general information respecting them, but now we never hear a word about them, a fact which leads one to suppose that they have been broken up. I remember a certain worthy doctor at Turnham Green once telling that science and £. s. d. world never agree, but that practice and £. s. d. world work well together. The latter, therefore, being the order of the day, I say practical information is the sort wanted. Now, for me to foreshadow anything like a comprehensive plan by which this object might be attained, would be assuming more than I have a right to do; nevertheless I may perhaps be allowed to throw out a few hints for the consideration of the fruit committee. What we cultivators as a class want to know is this, What kinds of fruit do best, and what sorts are unsatisfactory, in different localities? This surely might be got at by the Society instructing its pomological director to make a tour (but not by rail) throughout the country in different directions, and publishing the result. For example, Flemish Beauty Pear is really good at Chiswick, while at Arundel it is perfectly useless; on the other hand, Beurré d'Arenberg is bad at Chiswick, but first-class at Arundel. At Frogmore, Knight's Monarch is perfection itself, but at Blackmore, Essex, though in the best soil I ever put a spade in, it is simply useless. At Thoresby, in Nottinghamshire, Winter Nelis does well, while here it refuses to grow larger than a walnut, and is quite useless in flavour. At York, Swan's Egg is very fine, while in the south of England it is bad. The same holds good with Apples and other fruits. I may be told that, as gardeners, we ought to know all about these matters. So we do in our own localities; but we are such a migrating race that to day we are here, while in a month we may be one hundred miles away, and be called upon at once by our new employer to replant or make new fruit gardens—a critical matter when we are strange to the locality. If the information was given the necessity for which I have so imperfectly tried to point out, we should be in a better position to fulfil such a duty as that just alluded to. Much might be done in the matter by gardeners themselves, if we could only persuade them to state their experiences in reference to the fruits they find to succeed best; but so many say, "I cannot write"; to such let me say, Fear not, give the Editor of THE GARDEN your ideas, and leave the rest to him.

R. GILBERT, Burghley.

ASPECTS OF VEGETATION.

MADAGASCAR ORCHIDS.

Our gardens are indebted to the Rev. Wm. Ellis, of Hoddesdon, for two fine kinds of *Angraecum*, viz., *A. superbum*, a fine variety of *A. eburneum*, bearing blooms of large size, and of ivory whiteness; and *A. sesquipedale*, a wonderful plant, certainly one of the finest of its class. The way in which these and some other orchids grow in Madagascar is thus described by Mr. Ellis:—

"Orchids were abundant, and often occupied positions in which the growers of these plants in England would little expect to find them, but in which they gave an indescribable singularity and charm to the landscape. The limodorus were numerous in parts of the road, and formed quite a ball of interlaced roots at the base of the bulbs. A small species, resembling in habit and growth the *Camarotis purpurea*, but quite unknown to me, and bearing a vast profusion of white and sulphur tinted flowers, often enlivened the sides of the road along which we passed. But the angracums, both *A. superbum* and *A. sesquipedale* were the most abundant and beautiful. I noticed that they grew most plentifully on trees of thinnest foliage, and that the *A. sesquipedale* was seldom, if ever, seen on the ground, but grew high up amongst the branches, often throwing out long straggling stems terminating in a few small, and often apparently shrivelled, leaves. The roots also partook of the same habit. They were seldom branched or spreading, but long, tough, and single, sometimes running down the branch or trunk of a tree, between the fissures in the rough bark, to the length of twelve or fifteen feet; and so tough and tenacious that it required considerable force to detach or break them. Many of these plants were in flower; and, notwithstanding the small, shrivelled appearance of the leaves, the flowers were large, and the yellow colour strongly marked. On more than one occasion I saw a splendid *Angraecum sesquipedale* growing on the trunk of a decaying or fallen tree, as shown in the accompanying engraving, and sending

Strichnos Tree, with Orchids (*Angraecum superbum*) growing on the Trunk and Branches.
Sago Tree (*Cycas circinalis*) in the distance.

its tough roots down the trunk to the moist parts of the vegetation on the ground. I found one decayed tree lying on the ground almost overgrown with grass and ferns, on the rotten trunk of which the *A. sesquipedale* was growing most luxuriantly. The roots which had penetrated the soft trunk of this dead tree were white and fleshy, while the leaves were longer and comparatively soft and green. There were neither flowers nor flower-stalks on any of the plants growing in the rich vegetable mould furnished by this old dead tree.

The habits of the *superbum* were quite different. Of these the fleshy roots formed a sort of network at the base of the bulb. During the journey I occasionally noticed both kinds growing not only on the branches of living trees, but very often high up on the bare barked trunks of the dead trees. Sometimes in the angle formed by the junction of an arm with the trunk of a large naked tree, apparently without a fragment of bark adhering to the trunk, a bunch of moss, or a cluster of orchids, or both mingled together, would be growing apparently with great vigour, and often in full flower. More than one tall bare trunk, twelve or eighteen inches in diameter, and thirty feet high, stood surmounted, or surrounded near its summit, by a cluster of angracums, with their long, sword-shaped, fleshy leaves; or, what was more beautiful still, a fine specimen of some species of birds-nest fern. The contrast between the white, shining, barkless trunk, and these verdant clusters of plants on the top, was sometimes very striking; especially as the orchids were often in flower, and by their growth altogether suggested the idea that by the decay of their own roots a receptacle was formed for the moisture or the rain by which the plant was nourished. This combination of life and death, growth and decay, presented one of the most singular amongst the many, to me, new and curious aspects of nature which my journey afforded."

In some parts of Madagascar numbers of Orchids are to be found growing luxuriantly in most picturesque positions.

We are indebted to Mr. Ellis's interesting work, "Madagascar Revisited," for our excellent illustration of tropical vegetation.

SOMERLEYTON GARDENS, SUFFOLK.

(Continued from page 490.)

LET us advert once more to the glasshouses at this fine place. Their elegance as regards construction will be made apparent by our illustrations, and it will be seen that they are amply ornamented with statuary. Amongst the conservatory corridors, of which there are several, the one we have selected for illustration is perhaps the most striking. It is a hundred feet long, and of proportionate height and width, terminating with a noble statue, of which we have given a separate illustration somewhat magnified. Grand and costly statuary, indeed, forms a conspicuous feature in the embellishment of this princely establishment; for, look where you may, your eyes are sure to rest on some magnificent work of art of this kind; nor is this the case in the conservatories only, for in the flower gardens, pleasure grounds, and, in fact, everywhere in the immediate vicinity of the mansion, statues abound. An elegant drapery of climbing plants, it will be seen, decorates the pillars, trellises, and arches of the corridors in such a natural and enchanting way as to set their beauties off to excellent advantage. All the climbers here are grown in borders, where their roots are allowed to ramble comparatively unrestrained, a plan greatly superior to that of confining them in pots. Vases, some sixty or so in number, tastefully filled with suitable plants, also give additional charms to this structure. The seats which line the side of the corridor, as seen in the illustration, may be either used as resting spots or as stands for pots or vases.

The Palm House is entered through a noble archway, in front of which is a magnificent marble statue of "Hymen," by Byrröm. Behind this fine piece of sculpture will be seen the tall and graceful forms of Dracaenas and Palms, together with other types of a noble and luxuriant vegetation. The Palms are clothed with a fine and healthy foliage, and even those whose pots are raised some feet above the ground are well furnished with leaves.

The kitchen garden is devoted solely to the production of vegetables and herbs, with the exception of a herbaceous border along both sides of the centre walk. It contains no fruit trees, for which provision is made elsewhere. In size it is a little over an acre, and is surrounded on all sides by high brick walls. The whole of the south aspect of the wall on the south side of the garden is covered with glass, under which peaches and nectarines are grown. This house is crossed in the centre by a walk which runs through it at that point into the kitchen garden. Its front has a height of six or seven feet, and has a wide trellis inside, on which the trees are trained; the back is also covered with fruit trees. The west side of the east wall is covered with lean-to houses, in which vines and figs are grown to perfection. The south side of the north wall is also covered by lean-to houses, which, instead of being

glazed in the ordinary flat manner, are on the ridge and furrow system; but as this system exposes the roof more to the action of wind than a flat surface, it is not considered so good as ordinary glazing. These houses are divided, like the others, into various compartments, each being devoted to the culture of vines and peaches, under the shade of which bedding-plants, &c., are grown. The vines are mostly young, and very promising. Their roots are planted inside the house, the borders for which are separated from one another by means of slates, which divide them into separate compartments from the surface to the drainage, so that no communication whatever exists between the roots of different sorts. By this means should any accident befall one plant, the root could be examined and, if necessary, removed, and the border renewed without any damage being done to the others. The peach houses in this range are filled with some fine old trees in capital condition, and loaded with fruit. One division alone is filled by Noblesse peach trees, the others are planted with Royal George, Late Admirable, Téton de Venus, and other peaches, together with various kinds of nectarines. Both sides of the west wall are covered with fruit trees. At the back of the north wall are the mushroom houses, and other buildings usually to be found there. A few yards farther north are ranges of forcing pits for asparagus, pines, salads, and other vegetables; also for bedding plants. These pits are all heated by hot-water pipes.

Contiguous to this is an apple orchard of about two acres in extent, in which the trees bear heavy crops of good fruit. The ground is uncropped with any kind of vegetable; but nevertheless it is dug every year, and throughout the summer kept neat and clean by means of the hoe and rake. Close pruning is not so much practised here as in many places, for Mr. Hopkirk, the gardener, considers that by otherwise carefully attending to the trees, removing from them useless and un-

productive branches, and keeping them in a condition easy of access for fruit gathering—a method similar to that pursued by the market gardeners—he reaps a more plentiful harvest than by otherwise using the knife so severely as is generally done. Apart from this is a pear orchard of about an acre, which is also similarly treated.

Seldom have we seen peach trees more promising than those in this establishment, in which there are some very old trees; one of these is planted near the middle of a division of one of the fruit houses, and its branches are trained in all directions along the roof, completely filling the house. The next compartment is occupied by three trees, one in the middle and two in the front of the house; these old trees are loaded with fruit, notwithstanding a heavy thinning to which they have been subjected. Pine-apples are grown here in frames, in which bottom heat is supplied by means of hot-water pipes. One set of frames is devoted to fruiting plants, another to

Somerleyton Gardens.—Corridor in Winter Garden.

succession plants, and a third to suckers; and seldom have we seen plants in finer condition, or producing better flavoured fruit. The furthest advanced of these are now approaching maturity. The kinds grown for winter use are the smooth-leaved Cayenne and Black Jamaica; those for summer consumption are confined to the Queen variety, off which Mr. Hopkirk obtains annually a heavy crop of large and fine fruit.

Through the liberality of the proprietor, these gardens are open to the public every Wednesday throughout the year.

THE SIX OF SPADES,

CHAPTER XI.

The President's Lecture—(continued).

AND now must I confess, with a blush upon my cheek as deeply crimson as Senator Vaisse, well described in the Rose Catalogues as "intensely glowing scarlet," that for some fifteen years of my existence I walked "this goodly frame, the earth," with about as lively an appreciation of the beauties of a garden as may be supposed to be experienced by a collared eel. Abruptly and completely, like a coquette deserting a baronet for a peer, I transferred my affections from Flora to Pomona, and became miserably oblivious of all flowers pleasant to the eye, in my absorbing greediness of all fruits, which I erroneously supposed to be good for food.

I have not, my dear Brother Spades, I assure you, one unkindly thought against apples; I have not a detrimental remark to make against gooseberries, however green. Childhood, I know, will distend its little self, boyhood will fill its large pockets, and youth must have its sting (at the pear tree), whatever age may preach. For myself, so far from sermonizing, I thoroughly admire that magnificent digestion, which is no longer mine; I fondly desiderate that glorious palate, for which no Magnum Bonum was too unripe; and I mournfully envy those noble grinders, which were not afraid to grapple even with the peach's iron stone.

But while I speak approvingly of this early fondness for fruit, and say of it, as Sam Weiler said of kissing the pretty house-maid, that "it's Natur, ain't it?" I see no reason why a fondness of flowers should not be developed contemporaneously, or why in childhood and boyhood, and in many cases throughout manhood too, the sense of sight and of smell should minister only, so far as gardening is concerned, to the gratification of our tongues and throats, and cease to co-operate with the heart and brain. Why should not that love of the beautiful, which is innate in every exile from Eden, be encouraged by our pastors and masters, with as much care and attention as the Greek grammar? Why should not our schools—and there are many, thank heaven, in which refinement of taste is no longer derided, and where it is no longer considered effeminate to avow an admiration of the works of God—why should not

these schools have their garden as well as their playground? and why should not those who will hereafter have gardens of their own be instructed in that happiest and most useful of all sciences, horticulture? What arts could be better worth learning than those of making our homes beautiful, of providing ourselves with a never-failing source of innocent gratification, and of supplying to those around us the continual refreshment of delicious fruits, with a healthful abundance of those vegetables, which are adjuncts, as excellent as they are economical, to every man's daily food.

From these plants you will infer, my friends, that I had small encouragement in my earlier years to foster my first love of flowers, and that I received no instruction whatever in the gentle craft of the spade. Once or twice during my schoolhood the old light emitted a feeble ray, and I was so far illumined on a special occasion as to lay out ninepence on a Fuchsia. It

was received, I recollect, on its arrival from the nursery, with a great profession of regard and admiration from several of the bigger boys, and they proceeded at once to demonstrate their affection by administering a variety of liquid manures, such as blacking, sour beer, and mustard, which they assured me, on the authorities of gardeners at home, who had made the Fuchsia their special study, would cause an immediate and gigantic growth. But when they proceeded, "according" (so they said) "to the invariable practice at Kew Gardens, and to the principles laid down by Dr. Lindley," to distribute a fire shovel of hot cinders around my poor little plant, credulity gave place to bitter tears; and though I had the subsequent satisfaction of definitely discomfiting in five rounds a young gentleman, who thought to improve the occasion by addressing me as a "snuffing softy," I took heart no more during my scholastic term, to exhibit single specimens in pots.

In the groves of Academus (to use that beautiful diction, which is a trifle more appropriate to the groves of Blarney) there

prevailed, floriculturally speaking, as remarkable a dearth as dreariness. Beneath the trees of those renowned plantations, which dip their metaphorical branches in the limpid waters of Isis and of Cam, we grew nothing but Scarlet Runners (undergraduates in hunting costume, swiftly darting from quadrangle and cloister to avoid collegiate and proctorial authorities); a few Stocks (the freshmen wore them, when there was not the same connection as now between a Buckle and Civilization); and a large assortment of Bachelors' Buttons (straps being the fashion in those days, and wrist-studs unrevealed).

We attended, it is true, with a prompt punctuality the flower shows in "Worcester" Gardens, and no one could gaze more earnestly than we did upon those very delicate Roses and Tulips, which require the protection of a bonnet. We came away, moreover, with quite a longing for Heartsease, and were ourselves most perfect examples of Sensitive Plants and of

Somerleyton Gardens.—Statue at end of Corridor in Winter Garden.

Love-lies-bleeding. But all this in figure, and that figure a cipher. We never looked at the flowers, nor thought of them; and when I was asked by a floral friend whether I had seen that lovely *Polly-anthus*, I urged him, to his grand amusement, to point out at once the beauteous *Mary*, and, if possible, to introduce me. I never met him afterwards, but he had something facetious, as he supposed, to say in reference to my mistake, "Should I like to know the fair *Hannah-Gallis*, the charming *Carry-Opsis*, the celebrated *Miss-Embryanthemum*, the two great heiresses *Miss-Gold* and *Miss Annie-Money*? Had I seen anything latterly of *John-Quil*, *Bill-Bergia*, or *Stephen-Otis*; of my Scotch friend, *Mac-Rauthus*, or my Irish friend, *Phil-O'Dendron*?"

And so, sans ears, sans eyes, sans nose, I wandered, flowerless, through a flowery world. Some, perhaps, may tell me that it was better so; that boyhood should find its recreations in active games, and youth in the sports of the field; and that floriculture is incompatible with that hardy physical training, which hereafter is to make the man. But I designate this doctrine humbug. Why should a boy be less brave or strong, if taught to appreciate the beautiful things about his daily path? or why should youth ride more timidly to hounds, because it had a flower in its coat? There is a time for all things. A time to tend some graceful plant, as well as to kick a foot-ball; a time to store the heart with gentle attachments and refined tastes, as well as to run and row; a time to develop the intellectual as well as the physical powers.

At length, to revert to my own history, a brighter morn dawned upon my darkness. A single star, twinkling in the firmament, first told the advent of a joyous day; and that star, my friends, was—a ROSE!

CHAPTER XII.

The President's Lecture— (continued).

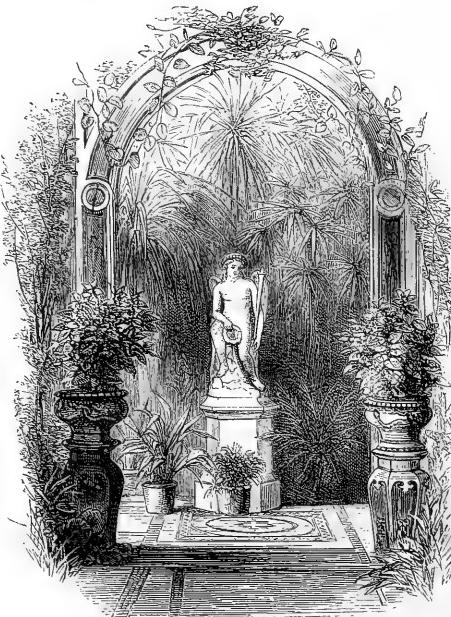

As a look, a gesture, a picture, a song, a perfume, may suddenly transport the mind to things and thoughts, forgotten half a life, so did this rose, a *Salvator Rosa* to me, at once revive that early fondness for flowers, which had slept, as paralysed as Merlin in the oak, since my childhood laughed among the cowslips. The ice broke with an instantaneous crash, and set the river free; the fog disappeared before that single sunbeam as swiftly as the spectre army which beleaguered the walls of Prague; and it was summer-tide once more. Anatomists tell us of cases in which the brain, accidentally injured, or otherwise oppressed, has been relieved after long incapacity, and its powers restored; we have an account, for example, in the *Edinburgh Review*, and in an article upon "Brain Difficulties," of a young gentleman whose sagacity was considerably enhanced by a well-timed kick from a horse; and so was I on an analogous principle successfully trepanned by Dr. Rose, and my floral apprehension again put in working order. The clock struck only one, but, like the remorseful villain in the

tragedy, I "remember to have heard a clock strike in my infancy—I am overcome—I burst into tears—and become a virtuous and exemplary character for ever afterwards."

Sitting in the garden one summer's evening with cigar and book, and looking up from the latter, during one of those vacant moods in which the mind, like the Jolly Young Waterman, is absorbed in "thinking about nothing at all," my eyes rested on a rose. It glowed in the splendour of the setting sun with such an intense and burning crimson, the tints of vivid scarlet gleaming amid the purpler petals, as light in jewels or in dark red wine, that I shall never lose my first admiration for rose *D'Aguesseau* (*Gallica*), although, having accomplished the mission entrusted to her by Flora for my restoration, she has never since appeared in my rosarium in such resistless beauty. But I ever think fondly of my first fair love, remembering among a thousand charmers the darling of my early youth, as the heart of man is prone. Blue-beard himself, I do not doubt, was wont sometimes to muse with special satisfaction upon the fascination of that young lady on whom he first lavished his affections and subsequently tried his carving-knife.

The next evening found me in my accustomed seat, but my cigar was exchanged for a pencil, with which I was making careful notes, and my book was "Rivers on the Rose." This dear little Red Book, *coulour de Rose*, so earnestly, so gracefully written in a language which, as Lord Macaulay says of Livy's, is "always fresh, always sweet, always pure" (he might have been describing a rose)—this guide to amateurs, which has brought so much happiness to the neophyte, so much instruction to the learner, so many glad memories and genial sympathies to all rose-growers, quite completed my conversion. In that pleasant manual there is a hearty, loyal fondness for the theme, a truthfulness of description, which cannot fail to charm. It seems to say, with the perfumed earth in the Persian fable, "I

Somerleyton Gardens.—Entrance of Palm Stove.

am not the rose; but cherish me, for we have dwelt together;" and there is fragrance as of roses among its leaves. There can hardly be a treatise with less affectation and superfluity, so genuine, explicit, and natural, and so exact a transcript of the man from whom it comes, that when I made his acquaintance, some years after my transformation, he exactly verified my expectations, and it was like meeting with an old and valued friend.

And thus I discovered, if not "books in the running brooks," a most fascinating volume in the *Rivers of Hertfordshire*, and in it plunged, as keen as Cassius (to Cæsar's unspeakable disgust), and as eagerly as a hot schoolboy taking "header" into his favourite pool, truant, it may be, and destined after his ablutions to the coarsest kind of towelling, but for the time as oblivious of all the ills which the fleshier part of youth is heir to, as though he bathed in Lethe. And just as this amphibious juvenile will emerge from time to time and diversify his

sport by a periodical canter in the flowery mead, so I quitted my Rivers at intervals, and wandering among my roses (I had but a dozen then) tendered my tardy but devoted allegiance. Or as a pupil at Dotheboys Hall would be requested, after spelling the word "horse," to go and clean the quadruped in question, so I went from description to reality, first studying the portraits in my Book of Beauty, and then doing homage to those fair originals, born, or rather budded, so long to blush unseen, and waste their sweetness on my father's heir. How delighted I was, first to read, and then to have ocular proof, that Boula de Nanteuil was a "standard of excellence" (mine was only a half standard, but let that pass); that Kean was "always beautiful, in size first-rate, and in shape perfect" (Mrs. Kean herself could not wish for a more flattering portrait); that Coupe d'Hebe was "the gem of the family," and there, sure enough, I found her, a cup for the gods and jewelled with dewdrops; and how disappointed I felt as I read that Madame Laffay "ought to be in every garden," but could not find her in mine, soon consoling myself, however, in the presence of Baronne Prevost and Duchess of Sutherland, and, on the whole, as well pleased with my new friends as was the author of my book when, one morning in June, looking over the first bed of roses he had ever raised from seed, he saw growing with great vigour one of the very few good roses then originated in England, and subsequently called, perhaps because robust in habit as poor Brummel's "fat friend," Rivers's George the Fourth.

If this account of my resuscitation—if the suddenness with which I cracked the cocoon of my grubship and came out a rose-loving butterfly, appear to any of my hearers to be too severe a test of their implicit confidence in the narrator (in coarser English, "a corker"), I have testimony at hand to confirm my statements, and Mr. Evans is here, like the statue of Horatius, "to witness if I lie." He will readily recall his great astonishment when I first began to speak to him of flowers; how he smiled encouragingly upon me as a mother upon the baby just "beginning to take notice" ("bless it!" exclaims mamma; "it's worth a million a minute!"); and nurse immediately follows with, "Yes, mum, two!"); and how he would gaze upon me with an expression of kindly hope, as though he were some good physician, watching in his patient the first symptoms of recovery from delirious fever. He will recollect how rapidly our rosarium spread, since, as the Poet of the Seasons sings—

"By swift degrees the love of Nature works,
And warms the bosom, till at last sublimed
To rapture and enthusiastic heat."

until it finally invaded the kitchen garden, and drove out the Asparagus at the point of the digging-fork; and he will rejoice with me in remembering the time when our hostilities terminated; when Mars was to influence us no more, although that deity, according to Hesiod, was the son of a flower, and not of a gun, as one would be more disposed to imagine; when we turned our bayonets into pruning-knives, our swords into scythes, our mortars into garden rollers, our helmets into flower-pots, our uniforms into shreds for the wall-trees, and our trumpet of war into a bird-tenter's horn. S. R. H.

(To be continued.)

GARDENING ROUND LONDON. (DURING THE PRESENT WEEK.)

PRIVATE GARDENS.

SPECIMEN plants of Hederaeas, Chorozemas, Azaleas, &c., are now being retarded or advanced, so as to suit the purposes for which they are intended. Pelargoniums for exhibition are being trained into proper form, and placed on inverted pots so as to be fully under the influence of light. As they are usually grown in small pots compared with the size of the plants, the pots are placed on a little damp moss, which serves to keep the roots in a moist condition; a little manure water is also given them occasionally. To Heath's abundance of air is given on all favourable opportunities. Erica Massoni, a fine Heath, is apt to produce a quantity of young shoots in the centre, which require thinning, for if too thick, mildew is likely to be generated; the thinnings make cuttings, which strike root more freely than the points of better placed shoots. Allamandas

are being trained round trellises or stakes. Stephanotis and Dipladenias are plunged in coco-nut fibre, and their young shoots are trained to thread fastened crossways to the roof of the stove; under this comparative freedom they grow better than when tied to trellises. When the shoots have attained sufficient length and set their flowers, the threads are cut, and they are then trained around the trellises, which are thus furnished at once with flowers and foliage. In retarding Phalaenopsis it is customary to pinch out the first flower spikes, a mode of management which answers very well in the case of *P. amabilis*, but *P. Schilleriana* seldom pushes again after the first pinching, a point worth the attention of beginners in orchid culture.

Pits and Frames.—Dahlias separated from the parent tubers, and having good roots, are planted out in cold frames in good light rich soil, sashes or mats being placed over them; they are kept close for a time, and afterwards gradually exposed. Cannas started in heat are placed in frames, and kept rather close for a time. Young Chrysanthemum plants are shifted as they require it, kept near the glass in cold frames, well watered, and have the sashes drawn off altogether in fine weather. Balsams are never allowed to become pot bound; on the contrary, as they advance in growth, they are kept regularly shifted; the best place for them being pits or frames heated with dung and leaves; air is given on favourable occasions by tilting up the sashes at front and back, and even during mild nights they are left about half an inch open at the back. Half-hardy annuals sown in pots, pans, boxes, or broadcast in frames, are thinned, and the thinnings are used for transplanting; air is freely admitted, and water plentifully but carefully supplied, especially in the case of Stocks, which are liable to damp off. Cinerarias for late flowering are kept as cool as possible. Calceolarias are now throwing up flower spikes, and are neatly staked. Of Cinerarias some seeds are now sown, and from the earliest bloomed plants offsets are obtained, which are separated, preserving the small rootlets, and potted in sixty sized pots, kept in cold frames, rather closely shaded for a time, but after they have taken root fully exposed. Bedding plants in frames are being hardened as the weather permits, and where time and convenience can be spared, where three or four Geraniums were placed in a pot they are shaken out and potted singly. Verbenas, if not required for producing more cuttings, are also placed in cold frames. Boxes for window decoration are filled with various plants, and established in gentle heat.

Flower Garden and Shrubbery.—Evergreens newly planted are copiously watered and mulched. Hollies and Rhododendrons continue to be transplanted, lifting with them good balls of soil. Preparation is being made for the summer display of bedding plants by edging, manuring, and digging beds that have not been filled with spring plants. Much manure is not wanted, except the ground is very poor; but fresh maiden loam and leaf mould are sometimes beneficial. Succulents, such as Echeverias, Sedums, and Semper-vivums are planted around small bellas as edgings, &c. Plants of Saponaria calabrica sown and reared on wall borders are transplanted where they are to remain for blooming. Sweet Peas, Nasturtiums, and Tropaeolum canescens raised in pots and boxes are also transplanted permanently. These are likewise raised on sheltered borders, as are also many kinds of Everlastings. Stocks and Aster are now sown on warm south borders for transplanting; should there be any danger of frost, branches of evergreen bushes, mats, &c., are placed over them.

Indoor Fruit Department.—Pines now receive plenty of water and heat; the fruit is tied neatly to stakes, and where size is looked for, all suckers as they appear are removed. Grapes colouring have the atmosphere kept rather drier than ordinary. Thinning, stopping, and tying of Vine shoots are attended to, and inside borders are particularly guarded against getting too dry. To Figs swelling, abundance of water is given. Peaches past the stoning period are thinned to the required distances apart. Strawberries ripening fruit are kept somewhat dry; to those swelling, a little manure water is given, and those in flower have the hand passed gently over the trusses occasionally to assist fertilization. As soon as the soil of Melon beds is filled with roots, they are topdressed, packing the soil firmly, and placing over it an inch of loose mould. Overcrowding of shoots or foliage is prevented by thinning, and single flowers are not allowed to set; on the contrary, all are removed until a fair crop can be set at once. Cucumbers are not permitted to bear too heavy a crop at one time; thinning and surfacing, as for Melons, are being carried into effect, except that the compost used is not so firmly packed, and is of a richer and more open character than that for Melons. Vegetable Marrows are sown, and some are ready for transplanting permanently. Tomatoes continue to be potted and hardened off.

Hardy Fruit and Kitchen Garden Department.—In some cases the disbudding of Peach, Nectarine, and Apricot trees

has commenced; protection from frosts cannot yet be dispensed with, and great care is exercised to guard against strong sunshine in the mornings after frost, as much damage is sometimes done by brisk sunshine at that time. As a protection against the attacks of green fly, the trees are now and then syringed with tobacco water. Double-bearing Raspberries are cut down to within a few inches of the ground, to encourage autumn fruitfulness. Asparagus beds for the present have all their produce cut, i.e., none are allowed to run up, except perhaps here and there a stem or two for seed. Full sowings are now made of Salsify, Scorzonera, and Skirret, in lines a foot apart. A few seeds of White Dutch, and of red and white stone Turnips are now sown. Round-leaved Spinach is sown between lines of Peas and in open spaces amongst other crops. A late crop of Carrots is now sown in deeply-worked sandy loam, not too rich. Celery plants are pricked out and freely exposed. Peas are sown for succession; those up, have a little earth drawn to them, and staked. To Beans a little earth is also drawn. Of Beet, a main sowing is also made, and French Beans are sown in warm situations. Cauliflower for late crops are pricked out, as are also Cabbages, of which another small sowing is made.

NURSERIES.

Indoor Department.—Stove plants in general, that were repotted in March, are now making growth vigorously, and are copiously supplied with water at the root and overhead; a slight shade from strong sunshine is afforded them. Young Rhododendrons are being potted. Correas and other plants, the product of spring and winter grafting, are being re-potted. Azaleas done flowering are also being re-potted. These, Camellias, and Oranges, whilst young and making wood, are fully supplied with water both at root and overhead, as well as with heat and shade. Thus treated, they grow freely, and when growth is completed they are gradually hardened off. During active growth, Azaleas are generally cut in three times, which induces them to form fine stubby plants. Orange-trees, which stand the pruning-knife better than most plants, are also cut into proper shape. Plants of *Solanum capsicastrum* are likewise pruned well in, and are kept in cold frames; plants struck from cuttings are re-potted, and kept for a time in an intermediate house. Statices are being propagated by means of single cuttings put in small pots under a hand-light in heat; those that are rooted are shifted into larger pots. As many cuttings as can be obtained from the variegated *Mesembryanthemum* and Thyme are being struck. Roses are also being struck from cuttings in heat. Crotons are being struck by taking off good-sized shoots and inserting them in small pots, in sifted peat and silver sand in about equal proportions, covering the pots over with a layer of silver sand. The pots are then plunged in coco-nut fibre under hand-lights in strong heat. Those rooted are shifted into larger pots, plunged, and subjected to a high moist temperature. Where it is desirable to increase the fine kinds of Pandanus, such as P. Veitchii, a few of the lower leaves are removed, so as to induce young shoots to push from about the base of the stem. When these have grown to a tolerable size, they are cut half-way through, and allowed to remain thus for a few days, when they are finally removed, inserted, and treated as Crotons. Should the old plant be leggy, it may be cut down, the stem cut up into pieces, and inserted in coco-nut fibre under hand-lights; these soon begin to push from all the eyes, and as they advance in growth they are taken off with a heel and treated as cuttings. Seedling *Priularas* are pricked out into boxes. Daturas from eyes and cuttings are being potted singly; as are also young *Hydrangeas*. The propagation of bedding plants is still vigorously followed up.

MARKET GARDENS.

CUCUMBERS planted out in frames are protected at night with litter, which is placed over the sashes, and removed in the morning; the points of the laterals are pinched out at the third or fourth joint, and the shoots are then pegged down with small wooden pegs. The hand-lights under which Vegetable Marrows are planted are, now that the weather is so cold, covered round with litter, which is also placed over the top during the night and removed to the sides throughout the day. Tomatoes established in pots, and those sown broadcast in frames, are fully exposed on all favourable occasions. Seedling Tomatoes are dibbled into six-inch pots filled with soil, and plunged up to the their rims in earth in frames, keeping them near the glass. After being thus pricked out they are shaded for a few days by means of some litter being shaken on the glass. Kidney Beans sown in frames are protected at night but exposed during the day; beds of these that were sown in lines under hoops covered with mats are now up, and throughout the day have the top mats removed.

Mushroom beds made in August last are still productive. A mulching of litter is still in some cases preserved about the crowns of Rhubarb, under which the leaf stalks come up tender and crisp. Asparagus is now plentifully obtained from the open ground. Fresh plantations of White Paris Cos Lettuce are being made; they are planted in sets of six lines at about eighteen inches apart, leaving a space of four feet between every six lines, which will shortly be filled with Vegetable Marrows. Lines of Lettuces are also being planted four feet apart, and between these two rows of winter greens are to be grown. The spaces between Vegetable Marrows are also sometimes sown with Spinach or Radishes. Leeks are raised in frames, and are now nearly as big as autumn-sown Onions; these are being planted out in lines in shallow drills drawn as for Peas, about eight or nine inches apart, and those still in frames are fully exposed. Onions sown broadcast over large spaces of ground are up and being cleaned. Marks or lines of four or five feet apart are made across the field; two men are then placed in every space between the lines, who with short hand hoes, about eighteen inches in length, and the blades an inch and a half or two inches in breadth, go through the crop loosening the soil and thinning the plants, which in so young a state are uninjured by trampling. Plantations of Thyme are being made under fruit trees, planting it with a dibber in lines eighteen inches apart. Young Celery planted in lines about three feet apart under fruit trees in December has now a little soil drawn to its base. Cos Lettuces and common Cabbages are tied round with pieces of matting to cause them to produce firm white hearts. Turnips of fair size are being obtained from the open ground; these are grown in six feet wide beds, and throughout the spring protected with litter like Radishes. Sowings of Turnips are also being made, as are likewise sowings of Sprouting Broccoli, Savoys, and Brussels Sprouts.

JAMAICA AS A TROPICAL GARDEN.

"**T**HERE is nothing to prevent Jamaica becoming, for the quality, variety, and commercial value of its fruit, the most noted spot in the world, when gardening shall be understood and the value of the art shall be duly recognized here." These are the words of the Governor himself (Sir John Grant), says the *Times*, and they put the truth of the whole case before us. The island is one huge tropical garden, and the trade to be done in such products, not only with this country, but with the United States, is beyond all calculation. In the Northern States of the Union the market for tropical fruits is "unlimited;" what it might be here we need not say. Some progress has been already made in this direction. The real *Bombay* mango has been imported, and is flourishing; two true varieties of *mangosteen* have been introduced, and four new varieties of the orange. As to pine-apples, all other specimens, compared with the *Jamaica* fruit, are, according to the Governor, impostures and delusions; in fact, he does not believe it possible to grow a really "well-flavoured" pine in the latitudes from which we obtain our supplies. Yet—and this is the fact to which attention should be given—until the year 1870 fruit had no place among the exports of the colony. Pine-apples to the yearly value of at least £30,000 are shipped from a neighbouring island, which, as Sir John speaks of the "excessively bad fruit," we had better not name; while all this time *Jamaica*, which could produce the finest pines in the world—incomparable for quality and size, and of infinite value for the London market—never sent out a shilling's worth, except "now and then a barrel by the mail steamer to a friend." Exactly so; and the like conditions have ruled in a hundred other cases of precisely the same kind.

It would probably have been impossible to persuade a planter of the last generation that a fortune might be made by growing fruit for New York and London. Yet Sir John Grant, a man of extraordinary acuteness and experience, sees in a future fruit trade the unlimited enrichment of the colony. Its oranges, pine-apples, bananas, limes, lime-juice, cocoa nuts, and other such products could not be surpassed in quality, and might be cultivated to any imaginable extent. Besides all this, the soil and climate are eminently suitable to the growth of precious drugs and plants. Bark is raised easily, the cinchona plantation being in a most satisfactory state. Then there are hemp and China grass of excellent quality, nor would any arrowroot be superior to that of *Jamaica* if it were but more carefully prepared for market. Here, it will be said, is a noble prospect for the colony. True, but it is a prospect only. Not until the very last returns is there shown any "tendency to the development of new industries requiring little capital and no extraordinary skill." It is the old story, "minor articles" are neglected, though they are the very articles which we want, and which the colonists could send us. However, *Jamaica* is fortunate in having a Governor who can discern the true capabilities of the island, and the true place for its industry in the markets of the world.

ROYAL HORTICULTURAL SOCIETY'S BIRMINGHAM EXHIBITION.

THE complete schedule of prizes for plants, fruits, flowers, and vegetables, has been widely circulated; and we are glad to find that it appears to have given satisfaction. The exhibition, as our readers are aware, will take place in June next, and will continue for five days, viz., from Tuesday to Saturday, June 25th to 29th. It will be opened by his Royal Highness Prince Arthur.

The chief display of palms, tree ferns, and the more important stove and greenhouse plants, &c., will take place in a lofty tent three hundred feet by eighty feet wide, which will be erected over a beautiful garden, designed by Mr. Gibson. At one end will be a fountain and rockery, over which a cascade will fall. Picturesquely grouped beds, covered with turf, will be arranged over the entire length, and these will be divided by wide gravelled walks. The beds will vary in elevation, so as to prevent flatness, and to aid in giving the *ensemble* air of naturalness.

As regards the prize list, we find that the sum of £1,659. 1s. is offered for competition, of which the Royal Horticultural Society provides £661. 18s., and the local committee £997. 3s. This amount is divided among 220 classes. For various kinds of plants £981. 11s. is offered; for cut flowers £263. 5s.; for fruit £155. 1s.; for vegetables £153. 19s.; for implements, and horticultural buildings, medals to the value of £105. 5s.

We are pleased to find that good prizes are offered for evergreen trees and hardy shrubs, as well as for alpines, succulents, and dinner-table decorations. The latter will be tested by artificial light. On the third day, the Queen of Flowers will hold a special levee; and as the prizes are large, we may expect a fine display.

We may mention that the implement committee have determined on substituting medals for money prizes. These medals will be of three kinds—gold, silver, and bronze; six—the total number of the kind first named—being offered in six divisions as follows:—1. For the best horticultural building. 2. For the best heating apparatus. 3. For the best collection of vases, or other garden decorations, suitable for outdoor purposes. 4. For the best collection of garden furniture. 5. For the best collection of garden machinery, tools, &c.; and, 6. For the best display of garden wirework; with liberty added to their number.

The council of the Royal Horticultural Society have agreed upon the following scale of charges for admission:—Non-subscribers: Tuesday, June 25th, 10s. 6d. (or by tickets purchased not later than the previous Saturday, 7s. 6d.); Wednesday, June 26th, 2s. 6d.; Thursday and Friday, June 27th and 28th, 1s.; and the last day, Saturday, June 29th, 6d. Subscribers of 2ls. will receive three admission tickets for the first day, and four for the second or either of the following days. Considering the liberality of this arrangement, it is not surprising that already more than £300 worth of these tickets have been taken, and we have no doubt, from the privileges they confer, the demand for them will be very great. A limited number of season tickets, available to the owners on all the days on which the show is open, will be issued at 10s. 6d. each, thus affording to all who may wish to make frequent visits the opportunity of doing so at a very moderate cost. The convenience and pockets of the masses have also been considered, for packets of the shilling tickets will be sold at the rate of fifteen tickets for 10s. 6d., and the employees in manufactories, &c., will thus be enabled to visit the show at a small cost. On the last day the charge will be reduced to sixpence, so that all classes of the community will be afforded an opportunity of seeing what we believe will prove to be the largest and best exhibition of plants, fruits, flowers, and vegetables, and certainly the most important and instructive collection of horticultural buildings, implements, and decorative appliances, ever brought together in this country.

THE BIRMINGHAM HORTICULTURAL EXHIBITION.

For so kindly inserting my last letter I beg to thank you. May I ask a second favour, in order that I may be enabled to lay before your readers one or two additional points which immediately affect the successful issue of the forthcoming horticultural exhibition.

I have now before me the code of regulations, and for all practical guidance to exhibitors they are about as open and undefined as it is well-nigh possible to frame them. Permit me to illustrate my meaning by supposing that eight horticultural builders compete, and that each one exhibits a distinct and separate class of building; builder number one exhibits, say, a conservatory; number two, a lean-to vineery; number three, a span-roof greenhouse; number four, a cucumber and melon house; number five, a length of peach walling; number six, a pine stove; number seven, an orchard house, and number eight, an improved form of strawberry house. Now, in the absence of any second or corresponding structure to any of these,

there can be no means of comparing; and I respectfully submit that no judge would be able to decide which constituted the "best horticultural building," or which would be entitled to an award. The fact is, each would be a "best" for the respective purpose intended, but for want of competition would be, so to speak, "disqualified."

Now in order to remedy this state of things, why not separate iron from wood houses, and place them under schedules A and B respectively, and then sub-divide each schedule into classes, enumerating what houses each class shall embrace? Every builder would be at liberty to elect into which class and schedule he would wish to compete. The date of entries should be limited to a given period prior to the show, and the applicant exhibitor could be made acquainted whether or not there were sufficient applications to constitute a competition in such particular class; if not, it would be futile for him to compete therein, and he would have an opportunity of selecting another class. Of course, if he afterwards determined to become an exhibitor in that particular class with a view to obtain "honourable mention," or a "special award" for what he considered a novel and meritorious production, so far so good; but some such arrangement as the foregoing would put each competitor in possession of a knowledge of what he was undertaking; also it would tend to inspire confidence, whereas under the existing arrangements all is uncertainty.

Again, why should not specific and suitable awards be made for a display of plans, models, machinery for ventilating, detached ventilators, ingenious fastenings for doors, best mode of shading, and construction of stages? I think these and many other parts of a house are open to some improvement, and claim to be noticed.

Respecting the best hot-water apparatus, I shall, with your permission, be glad to offer a few suggestions next week.

SEFTON PARK EXHIBITION.

A GRAND fancy fair and flower show is to be held in aid of the New Southern Hospital, Liverpool, in Whitson's week. It will take place in Sefton Park, on May 21st, 22nd, and 23rd, and is to be opened by his Royal Highness Prince Arthur. The ground to be covered is in the form of a gigantic cross with a central plateau, from which a fine view will be obtained of the four wings, along which the plants are to be arranged on grassy banks. The prize list is on a scale sufficiently liberal, we should think, to induce a good exhibition, and as the proceeds are to be devoted to so charitable a purpose, we trust it may be well attended. We observe that special prizes are offered to ladies for a group of natural flowers in an epergne or centre-piece for table decoration; beauty of arrangement and effect to be the test of merit. First prize, epergne, value £15; second prize, epergne, value £10. The flowers used for these designs need not, it is said, be grown in the garden of the exhibitor.

L A W.

WILSON v. NEWBERRY.

THIS was the case of the horses poisoned by eating yew tree cuttings, reported in THE GARDEN for March 23rd. The parties to the action are near neighbours, residing at Lewisham. The plaintiff's paddock, in which his horses were, and the defendant's garden, both abut upon a lane, which separates them. The defendant had employed a nursery gardener, one of whose men, without any directions from the defendant, and indeed against his will and in his absence, cut a yew tree, and afterwards threw the yew cuttings into the lane, and two of the plaintiff's horses put their heads over the fence and ate the cuttings, and were both killed. The plaintiff sued the defendant for the value, and the case was tried before Lord Chief Justice Bovill at the last assizes at Maidstone, when the cause of action was put entirely upon negligence. The jury, however, found that the tree was cut without the defendant's authority, and that the cuttings were put into the lane without the authority of the defendant, and that he had no knowledge that they were poisonous, and so the verdict went for the defendant.

Mr. A. L. Smith now moved, on the part of the plaintiff, for a new trial, on the ground that putting the cuttings against the plaintiff's fence was a trespass, and a wrongful act independent of negligence, and that, therefore, the defendant was liable for the consequences. The court, after some discussion, granted a *rulinist* for setting aside the verdict.

The Nightingale.—I see that one of your correspondents notices the arrival of this favourite songster. I heard its full song on the afternoon of the 11th inst., at Fairlight, near Hastings; and the cuckoo was heard in Beafont Park on the Sunday previous; I myself heard it first on the 14th, near my house.—JOHN SKINNER, Moorchurch, Hollington, Hastings.

CATALOGUES, &c., RECEIVED.

General Catalogue of the Hardy and Tender Plants Cultivated in the Botanic Gardens, Zurich; for sale or exchange.—Flower Garden Annual Directory and Catalogue of Bedding Plants, &c., grown by John Scott, Crewkerne, Somerset.—Descriptive Spring Catalogue of Choice Seeds for the Flower and Kitchen Garden, by Barr & Sudgen, King Street, Covent Garden.—Hardy Trees, Shrubs, Conifers, and American Plants, by Jas. Veitch & Sons, Chelsea.—List of Select Flower, Vegetable, and other Seeds, and New Plants, offered by Wm. Bull, Chelsea.—General Catalogue of Plants, by B. S. Williams, Upper Holloway.—Flower, Sub-Tropical, and Vegetable Seeds, by Wm. Rollinson & Sons, Tooting.—New Roses, Pelargoniums, Camellias, Azaleas, &c., by Wm. Paul, Waltham Cross.—Florists' Flowers, by T. S. Ware, Tottenham.—Florists' Flowers, by Downie, Laird, & Laing, Forest Hill, London.—Fruit Trees, Hardy Ornamental Trees, and Shrubs, by Paul & Son, Cheshunt.—Flower Seeds, by Wm. Thompson, Ipswich.—Flower and Kitchen Garden Seeds, by Butler, McCulloch, & Co., Covent Garden.—Flower and Kitchen Garden Seeds, Gardeners' Tools, Implements, &c., by James Dickson & Sons, Chester.—Flower, Kitchen Garden, and Agricultural Seeds, Miscellaneous Plants, Fruit Trees, &c., by Robert Parker, Tooting.—Vegetable and Flower Seeds, Garden Implements, &c., by Edmundson Brothers, Dublin.—Vegetable and Flower Seeds, &c., by Drummond Brothers, Edinburgh.—Cultural Guide, and Descriptive Flower and Vegetable Seed Catalogue, by Smith & Simons, Glasgow.—Select Flower and Vegetable Seed List, by Wheeler & Sons, Gloucester.—Garden Furniture, by Frederick Reynolds, Birmingham.—List of Subscribers to the Gardeners' Royal Benevolent Institution.—Second Annual Report of the Toxteth Park and Aigburth (Liverpool) Gardeners' Mutual Improvement Society.

ANSWERS TO CORRESPONDENTS.*

H. V. (Mr. Hole will finish "The Six of Spades" in THE GARDEN).—A SUBSCRIBER (your description puzzles us; the plant was probably *Gentiana germanica*).—PYRUS (the Japan Quince thrives well as an isolated bush, and as such is very beautiful on a sunny slope).—RUS (one of the many richly coloured forms of the common *Polyanthus*).—HARRIET (a desirable fruit, but not one to be grown in quantity or for a supply).—J. BARRON (no; they are retail prices).—AN AMATEUR (we do not from your note glean what condition your vine is in, or what is the matter with it. We propose shortly to publish a series of articles that will probably furnish all the information you require).—R. McC. (we will attend to your suggestion).—LORD E. (The Imperishable Hothouse Co., Beacon Hill, Newark, Notts).—T. C. T. (you probably mean *Acer rubrum*. Send us a leaf).—R. A. P. (your Lilies were probably dead when you bought them. Being a scaly bulb the Lily soon suffers from exposure to the air in shops, &c.).—N. H. P. and T. JONES (thanks).—SAKUM (next week). The Dartmoor subject is somewhat out of our way).—MRS. BURKE (next week).—MISS O. (we cannot say, as they are not manufactured in this country; but a good carpenter would be able to answer you. Your note next week).—J. GROON (many thanks. Next week).—MISS K. (a very pretty plant. Next week).—W. W. H. (your pear tree leaves and blossom do not appear to be suffering from insects. We should refer their injury to the alterations of cold, wet, and heat. Negretti & Zambra, we believe, sell a cheap thermometer, examined and certified by Mr. Glaisher).

EXHIBITION NEXT WEEK:—May 1st, Royal Horticultural Society, at South Kensington (Roses, cut and in pots, Auriculas, Azaleas, Orchids, Herbaceous Calceolarias, new plants, fruits, and vegetables).

THEY are growing their own peots out in Colorado, or seem at least to have entered upon this field of cultivation. As yet, the product seems imperfect imagination largely developed, with some deficiency in the sphere of accuracy, or perhaps we should say sobriety of statement. Here is a specimen from a local paper. The tendency to exaggerate the fertility of those great and often desert-like plains of the hotter parts of the West is well hit off here:—

"Is it where the cabbages grow so fast,
That they burst with a noise like the thunder's blast?
Is it where through the rich, deep, mellow soil
The beets grow down as if boring for oil?
Is it where the turnips are hard to beat,
And the cattle grow fat on nothing to eat?
Is it where each irrigating sluice,
Is fed by water-melons?
Is it where everything grows to such monstrous size,
That the biggest stories appear like lies?
Tell me, in short, I would like to know,
Is this wondrous land called Colorado?
You're right, old boy, it is?"

* All questions likely to interest our readers generally are answered in the various departments.

COVENT GARDEN MARKET.—April 26th.

. Flowers.—These are now abundant; those in pots consist chiefly of Azaleas, Rhododendrons, Tea and other Roses, Hydrangeas with immense heads of flower, Deutzias, Cytisus, Spiraea, Gardenias, Amaryllis; zonal, sweet-scented, fancy, show, and other Pelargoniums, in great profusion; Calceolarias, both bedding and hybrid kinds; Fuchsias, Nicotianas, Heliotropes, small and well-flowered plants of the Golden-rayed Lily, Saxifraga, Callas, still in good condition, Spring Heaths, Stock, Lily of the Valley, &c. Amongst those not in flower are Musk, Dracennas, Cyperis, Myrtles, fine-leaved Begonias, Ficus elastica, Passifloras, and many others, besides a great variety of beautiful ferns. Cut flowers, in addition to those of the plants just enumerated, consist of White Bouvardias, Stephanotis, different kinds of Orchids, Pinks, Narcissi, Tulips, Tropaeolums, &c., and summer bedding plants are also furnished in great variety.

Injury to Stone Fruits on Open Walls.—A most critical time has passed over for apricots, peaches, and nectarines on open walls. Notwithstanding the usual coverings of woollen and other netting, &c., as protectors of the blooms, and the anxiety evinced by every gardener at this season to do all in his power to secure for his employer a crop of these delicious fruits, it is sad to have to acknowledge our fear that the sudden transition of temperature, &c., has done its worse to the apricot crop at least for this year. The weakness of the apricot bud or blossom was very apparent at the outset of the spring, and after the continued cold, damp, hazy weather, with successive rain and snow storms, which we experienced at the end of March, it is to be feared, in the south at least, that the apricot crops have suffered greatly. We, therefore, hail with pleasure Mr. Ayres' fruit tree protectors, which appear to be steps in the right direction. But it is not fruit alone that has suffered; vegetables have also sustained injury. The early potato crop, which was looking prosperous and forward on the evening of the 19th instant, has been greatly hurt by the biting frost (five degrees) on the morning of the 20th—the haulm is blackened and destroyed to the ground. And what of the apple, pear, cherry, and plum blossoms, which were fully expanded on the morning of Sunday last? Nothing in the way of fruit-tree bloom could stand against such a surly bleak north-easter, with the glass at freezing and a drifting snowstorm for hours. I see that our gooseberry and currant crop is safe as yet, as are also cherries on walls, but peaches and nectarines are very scanty.—D. CUNNINGHAM, Moor Park Gardens, Herts.

The Name and Address of the writer are required with every communication, though not for publication, unless desired. Letters or inquiries from anonymous correspondents will not be inserted.

All questions on Horticultural matters sent to THE GARDEN will be answered by the best authorities in every department. Correspondents, in sending queries or communications of any kind, are requested to write on one side of the paper only.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C.: All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

Readers who may find it difficult to procure THE GARDEN regularly through the newsagents, may have the numbers sent direct from the office, at 19s. 6d. per annum 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsagents, at the railway book-stalls, and from the office.

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE ROSE SECRET.

It may perhaps interest your readers to hear that from the different articles which have appeared in *THE GARDEN* in reference to what is called "The Rose Secret," I got "a notion;" and instead of throwing my prunings away this spring I used them as cuttings, putting a whole lot of them—about a dozen or more—in (I am almost afraid to mention it) a marmalade jar filled with coarse sand and water, with sufficient of the latter to be about a quarter of an inch or so above the sand. I then plunged the jars into a slight hotbed (covered by a Rendle span-roof protector), and let the cuttings have all the light and sun possible—never shading once. This was about eight weeks ago. Last week I thought I would have a look how the cuttings were going on at the bottom, as they appeared very healthy at the top; fancy my delight to find that the new roots had covered the sides of the jar, and were matted together in such a way that I had to wash the sand away under a tap to be able to separate the cuttings without breaking the roots. I call this "striking like willows;" some bits with only one eye at the top struck almost better than any; others, where I put perhaps two eyes beneath the surface of the sand, have struck from every eye. I can assure you I never saw cuttings so well furnished with roots as these were.

Out of about 120 cuttings of some three dozen different kinds of Roses, I only missed striking fifteen, which I think is a very encouraging result; anyhow I shall consider it the road royal, and experiment again in a similar manner in summer, when I shall pay more attention to the preparing of the cuttings and the way they will strike the readiest. The beauty of my system is its extreme simplicity; the trouble or labour is *nil*; beyond the mere procuring of the cuttings, all one has to do is to leave the jars alone, only giving a little water from time to time to replace what has been lost by evaporation.

As to the size of cuttings, I have put in anything—thick or thin, pithy or woody, straight shoots or jointed ones, shoots with from one to six eyes—only taking care that the cut in every case was a clean one, such as a good sharp knife will make.

MAX KLOSE, *Rose Cottage, Chelford*.

SALAD CULTURE.

Most people like a good salad; but unfortunately, as a rule, when the days get warm the salads get poor, and consequently, just at the time when we should most enjoy them, it is almost impossible to procure them. This arises from defective cultivation. All our salad plants, to be tender and crisp, must be grown quickly; and to secure that important end, the weather must either be moist and growing, or the ground must be rich. A dry, hot spring generally results in poor salad plants. The exception to this rule is either in rich, naturally moist soils, such as may be found in the valley of the Thames, or in situations made artificially rich, and where in dry seasons an abundant supply of moisture can be ensured. Thus, for the growth of summer lettuce, I have a plot of ground heavily manured, deeply dug, and finely pulverised; and then I divide the ground into beds three or four feet wide, leaving a path between, and excavate the surface soil four inches, placing the soil in the paths. In the excavation I place well-rotted dung—cow manure, if the land is sand—tread firmly, and then return the excavated soil two inches thick, taking care to leave sufficient in the paths to raise them above the beds, so that they will re-

tain sufficient water to completely flood them at any time. Plant a plot thus prepared every three weeks or a month from the beginning of June to September, and a supply of crisp, succulent lettuce is certain up to near Christmas. Observe, however, that water must not be spared; and should the weather be hot and dry, sufficient to soak the beds a foot deep must be given every week or ten days at the furthest. When the young plants are thoroughly established, weak manure water prepared from guano or sheep's dung and soot may be given with advantage. The secret of growing fine summer lettuce is that the plants, from the seed state to final maturity, shall not receive any check. Place young plants upon poor dry soil, and they directly run to seed; plant the same upon the beds which we have described, and they directly assume that plethoric habit which is coveted by all salad eaters. A well-grown Cos lettuce should weigh, when fit for table, from two to four pounds; the Neapolitan little less; and Tom Thumb should present a compact heart as large, and nearly as firm, as a cricket-ball. That size it will readily attain if planted upon beds prepared as I have described, and not more than six or seven inches apart.

This course of treatment may be pursued up to the end of August; as winter approaches, however, more elevated ground must be selected, or the plants, from an undue accumulation of moisture, may damp off. Therefore, beds for winter lettuce should be in southern and sheltered (but not close) situations, should slope gently to the sun, and should be raised fairly above the surrounding ground, the paths being several inches below rather than above the level of the beds. Some of our market gardeners who grow lettuces so successfully, plant them upon a sloping bank, and place the plants under hand-lights or large bell glasses. The ground being prepared, the glasses are set down in line so as to nearly touch each other. Under each, according to its size, three, five, or more plants are placed at regular distances, and plants are also placed in the spaces between the glasses, and these form a successional crop. This is, however, found to be somewhat inconvenient, and hence small frames, which are readily ventilated, are preferred by some. Where space is limited, and it becomes necessary to utilise every yard, lettuce for the winter and spring crop may be successfully grown over asparagus beds. Thus in October, as soon as the asparagus has turned yellow, clear the tops away, and having removed the soil, fork the surface of the beds carefully over, and break the soil quite fine. Then lay on, two or three inches thick, a layer of rich compost, such as the dung and soil from a hotbed, and plant the lettuce out in the usual manner. For this purpose the plants should be strong, and they should be planted in rows six inches apart and four inches apart in the row, so that as soon as large enough each alternate plant may be taken out for use, and to make room for those remaining. These I cover with low light frames, which admit a gentle circulation of air, and protect the plants from cutting winds and rain. In this way I manage to get excellent lettuces in March and April—quite equal in fact to any to be found at that season in the London markets, to which they are so largely imported from the Channel Islands and from France.

As regards varieties the black-seeded brown Cos is perhaps the most hardy, and at the same time, when properly blanched, the most crisp and nutty in flavour. Then in the same section follow the Sugar-loaf Cos, which "turns in" without tying, and Perfection. These are the best of the brown Cos varieties, and to them may be added the green and white Paris Cos, or, as they are sometimes called, the London Market Cos.

Of cabbage lettuce the brown Dutch and hardy Hammer-smith are the hardest; but Tom Thumb and All the Year Round are more delicate in quality. It is well for winter and spring supply to plant equal quantities of each of the preceding, though with the protection of glass there is not much danger of losing them, especially if the precaution is taken in severe weather to protect them thoroughly with mats and litter.

I sow every three weeks from the beginning of March to the middle of September, the first and last sowing being under glass. The autumn and winter supply I get from the plants raised in June and July; and those grown from the latter crop should either be so planted as to be readily covered with a frame or some other kind of protector, or they must be raised carefully, with good balls, before they are injured by frost in

October, and be planted in an orchard house or some other place secured from frost and damp. Of course at that season damp is the chief danger with full-grown lettuces; hence they must be carefully guarded from rain, and they will require to be examined frequently to remove decaying leaves. Properly protected from frost and damp, the July-sown seeds yield a supply through the winter months; and then for the early spring those sown in August will be ready for use. One advantage of planting over asparagus beds is that, if you protect the plants with glass, by the time the lettuce are fit for use the asparagus with the protection will be starting into growth, and thus it may be had some two or three weeks before the natural season, and when it is of much more value. Upon very heavy soils young lettuce plants are liable to damp off. In such cases it will be found wise to surface the ground at the autumn planting half an inch thick with burnt earth, or, if this cannot be obtained, fine cinder ashes. Either will remove moisture, promote the growth of the plants, and prevent the intrusion of snails.

G. S.

NOTES OF THE WEEK.

— A WOMAN born April 17, 1772, planted a tree the other day at Isleworth, in commemoration of her hundredth birthday.

— It is announced in the *Revue Horticole* that a nurseryman of Toulouse has obtained a really good double white Zonal Pelargonium. It is now in the hands of M. Boucherat, of Lyons.

— THE translation of Le Maout and Decaisne's "Traité Général de Botanique," by Mrs. J. D. Hooker, is announced by Messrs. Longman as in the press. This is one of the noblest works on botany that has yet appeared.

— It is announced that the next exhibition of the Royal National Tulip Society will be held on May 25th, in the Botanic Gardens, Old Trafford, Manchester, when £60 will be given in prize money.

— THE Central Horticultural Society of France announces an exhibition of horticultural products, plants, implements, &c., in the Palais d'Industrie, Paris, in conjunction with the Fine Arts Exhibition from May 25th to 30th. All communications on the subject should be addressed to the secretary of the society, Rue de Grenelle, St. Germain, Paris.

— INDIVIDUALS who endeavour to perpetuate their names by inscribing them on seats in parks and gardens, &c., may be interested to learn, that recently a young gentleman of Bermondsey who cut his name on one of the new seats in Greenwich Park, has been offered by the magistrate the alternative of a fine of twenty shillings or fourteen days' imprisonment.

— DR. L. PFEIFFER, of Cassel, has published the two first parts of a work which will be useful to the systematic botanist, "*Nomenclator Botanicus*," being an alphabetical enumeration of the names of all classes, orders, tribes, families, divisions, genera, sub-genera, and sections of plants, published down to the end of the year 1853, with references to the authorities, systematic arrangement, synonymy, and first publication.

— At a recent meeting of the Court of Common Council, Mr. H. A. Isaacs moved a resolution to the effect that no steps be taken to reconstruct Farringdon Market until the court should have finally considered the modification in the plan and models. Mr. H. Harris seconded the resolution, which, after an animated debate, was carried by a majority of seven in a court of 103 members. For the present, therefore, the proposed reconstruction of the market remains in abeyance.

— THE employés of Mr. Cranston, of King's Acre Nurseries, near Hereford, having petitioned their employer to shorten the hours of labour on Saturdays from six to four o'clock, he readily conceded their application, for which the men seem universally grateful; and we have no doubt that it will prove the means of extending a kindly attachment between themselves and their employer. This is an exemplary act on the part of Mr. Cranston, and we should be pleased to hear of the same plan being adopted by others.—*Hereford Times*.

— THE cuttle-fish of the sea has a curious relative in the plant family. It grows in the southern parts of Africa, and is known by the name of Hook-Thorn or Grapple-plant (*Uncaria procumbens*). The large flowers of this truly horrible plant are of a lovely purple hue. They spread themselves over the ground, or hang in masses from the trees and shrubs. The long branches have sharp, barbed thorns, set in pairs throughout their length. When the petals fall and the seed-vessels are developed and fully ripe, the two sides separate widely from each other, and form an array of sharp

horned hooks. Woe be to the traveller who ventures near at such time! The English soldiers in the last Kaffir wars suffered terribly from this plant. While the Kaffir, unclothed and oily, escaped harmless, the European was certain to be made and held prisoner. Imagine one hooked thorn catching in a coat-sleeve. The first movement at escape bends the long slender branches, and hook after hook fixes its point in the clothing. Struggling only trebles the number of thorned enemies, and there is no way of escape, except to stand still, cut off the clinging seed-vessels, and remove them one by one.

— THERE has lately been presented to the Academy of Sciences at Paris, a round cut from the trunk of an *Eucalyptus globulus* of six years of age, which is nearly twenty inches in diameter. This colossus of the vegetable kingdom grows and develops itself with astonishing rapidity. Seeds planted in 1865, are already, 1871, trees of fifteen metres high, and sixteen inches in diameter, at one metre distance from the ground. From the experimental garden at Algiers, where it has been much cultivated, plants are distributed gratuitously to such colonists as wish to have it. This *Eucalyptus* has succeeded exceedingly well in Algeria, and becomes in a very short time a tree of enormous size.

— IN the House of Lords this week, judgment was given in the appeal of the Duke of Buccleuch against the Metropolitan Board of Works. The original action out of which this appeal arose was commenced in 1867, and was brought to recover a sum of £8,225, which had been awarded to the appellant by an umpire appointed under the provisions of the Thames Embankment Act (1862), as compensation for taking away a jetty in which the appellant had an interest, and for the appellant's interest in certain lands adjacent, being injuriously affected by the execution of the respondents' works, together with interest on that amount and the costs. At the trial the jury found a verdict in the duke's favour, and this their lordships now upheld.—*Globe*.

— PARIS is just now subjected to a peculiarly unpleasant visitation. For eight or ten days past it has been deluged by swarms of large, black flies, common enough in gardens, but seldom seen in cities. They settle down in perfect shoals on people's clothes, on the tables at Boulevard *cafés*, on the *trotoirs*—everywhere in fact. These unpleasant invaders have made themselves so great a nuisance, that M. Blanchard, a member of the Academy of Sciences, read a communication to that learned body about them. He stated that the scientific name of the fly in question is *bibio hortulanus*; that it is quite a mistake to suppose that it feeds on decaying animal matter; it has a *penchant* for *pruneurs*, fresh vegetables, and other good things in the leguminous world; and their great numbers are due to the fact that, the Commune last year having scared away the small birds that prey on their eggs, they have increased and multiplied to an extent unprecedented.

— A HANDSOME conservatory will form part of the attractions of the magnificent aquarium now being finished at Brighton. It will, for the most part, be in the natural style, and cannot fail to be a graceful adjunct to the many interesting features this structure may be expected soon to possess under the management of Mr. Lord. The rockwork portion of the aquarium, including the conservatory, is being executed by Mr. Pilham, a sufficient guarantee that it will be satisfactory. We regret to learn that the Town Council of Brighton have thrown all the obstacles in their power in the way of this fine aquarium, so likely to be of service to knowledge, not to speak of advantage to the town from a lower point of view. By preventing the necessary elevation, the Town Council has succeeded in completely ruining the external aspect of the building, which is buried almost out of sight. We regret this the more, as the establishment is likely to prove an admirable one. Internally the structure is all that could be desired.

— Too late in some countries, and just in time in others, people are learning what a folly it is to strip indiscriminately the face of the earth of its forest trees. Whole regions have been rendered arid and uninhabitable by the too free use of the axe. India has suffered much from this cause; Australia and America have cut down timber far too wildly; North Africa and Spain in ancient times lopped away forests which were the life of those regions; and we believe that the destruction of woods has been overdone in our own islands. A forest is a natural reservoir of water; it protects the rain which falls into it from solar evaporation, and thus feeds the underground springs. "Everyone should think twice before he lays axe to root;" and it is, indeed, almost a pity that the Greek idea is dead, which saw a Dryad in every graceful and picturesque tree. California has been wise in time. She has glorious forests, amid which tower giants of the vegetable world—those pines of the Yosemite Valley, for instance—beside which our grandest oaks would look like mere shrubs.—*Telegraph*.

THE FLOWER GARDEN.

THE WHITE LADY'S SLIPPER.

THIS is not so beautiful as the showy Lady's Slipper (*Cypripedium spectabile*), but it is withal a very beautiful plant, and quite distinct from any other kind known to us. The *American Agriculturist*, to which we are indebted for our pretty figure of the plant, describes it as of the natural size. We have seen it thrice this size in England, and from newly-imported specimens, too. There are six species of hardy Lady's Slippers in the Northern States of America, one of

Cypripedium candidum.

the rarest of which is the White Lady's Slipper. The lip, which is the conspicuous portion of the flower, is of a pure white, the rest of the flower being greenish. This rare little plant is found in bogs from Central New York westward. All the Cypripedians are worthy of cultivation, but they can only be grown successfully by imitating their natural conditions. They require a peaty, sandy, moist soil, and a shady situation, and under these circumstances their cultivation is not difficult.

NATURE'S FLOWER GARDEN.

A RAMBLE in spring through our woods and fields has a charm to my mind unequalled by few others of the pleasures of our existence. On every side we see plants in all stages of growth; some just bursting into life, and some already in flower, but all exemplifying the grand reproductive powers of nature. The bright sun overhead, lighting up, it may be, the drops fallen from a passing shower, the twitter and rapid flight of the swallow, the note of the cuckoo, seen and heard perhaps for the first time since their departure, all contribute to the buoyancy of spirits which a fine spring day brings

to those who are not too much borne down by this world's cares and sorrows. I am not much of a botanist—that is, I am not a scientific one—but I thoroughly enjoy such a walk through nature's "wild garden," and seeing and recognizing my old spring favourites on this their annual re-appearance. I have, too, my own special wild garden to replenish with any rarity with which I may happen to meet. To this end last week I made an expedition to a neighbouring wood, noted for containing an abundance of that rare native plant, the bulbiferous Bittercress (*Dentaria* or *Cardamine bulbifera*), and one which is well worthy of a place in a wild garden. This plant is, I fancy, not generally well known, as it grows in but few places in England. In flower it resembles the common Cuckoo-flower, or Meadow Bittercress, so abundant in our meadows; but the chief peculiarity about it consists in its white knotted rootstocks, like ivory, from whence it receives its name of Coral-root. The wood I refer to is charmingly situated in a hollow near a river, and was quite carpeted with plants of various descriptions. The dark green of the Dog's Mercury formed a pleasing contrast to the yellow flowering stems of the Wood Spurge; and almost every inch of ground was occupied by some more or less well-known plant. Here, later in the season, may be found, in great handsome clumps, the Willow Epilobium and the Nettle-leaved Campanula, with its elegant bell-like flowers; both of which plants might be introduced with advantage into our shrubberies, when they do not happen to grow in the immediate neighbourhood. After filling my bag with several roots of the *Dentaria* and other plants, I turned my steps towards the river. There also everything was beginning to wake up after its winter sleep, and in a few weeks the banks will be thick with vegetation—Epilobium, Comfrey, the yellow and purple Loose-strife, Hemp Agrimony, and many well known aquatic plants, too numerous to name, which add so much to the beauty of our native streams.

A visit to an old garden wall to ascertain the fact of the existence of *Asplenium Trichomanes*, and to a neighbouring churchyard to obtain a root of *Geranium pyrenaicum*, and my walk was ended. The expedition was not without its results, for I carried home a basket of plants to my wild garden, which will increase its beauty and interest in my eyes. A dried collection is doubtless a very useful and necessary thing, but, in my opinion, a small piece of ground set apart for the culture of our rarer native plants is a much pleasanter way of obtaining a smattering of botanical knowledge.

W. A. T.

FLOWER GARDEN FASHIONS FOR 1872.

MR. T. BAINES's last letter on the "bedding system," I am glad to say, makes it clear to my mind, that however his hands may have helped him, his head clearly has most to do with his deservedly high position. Of all the chinks in the gardener's armour, this one of the bedding system, which he exposes, is the weakest and the most glaring. There is really no such thing as gardening nowadays. Every establishment, big and little, has started a factory, in which every colour in the rainbow can be supplied at a month's notice, in any quantity, from six inches to six thousand yards. It is usual to laugh at the nobleman who ordered ten feet of theology, sixty yards of biography, and twenty of history, &c., to fill up his newly-erected library shelves; but his want of proper taste and appreciation is as nothing compared with that exhibited by those who plume themselves on their correct taste, and yet persist in sickening themselves and their neighbours with the namby-pamby and glaring mixture of vulgarity and formality which at present constitutes the bedding system. It was all very well for the first few years to astonish one's neighbours with ; but the old conundrum gets dreary when you have heard it asked and answered thousands of times before ; and it is no wonder that your visitor, when you show him your ribbon border, and ask his opinion of it, replies, that "he has, as nearly as he can measure, seen about sixty miles of exactly the same pattern," and asks you as a favour to be allowed "to cool his eyes on the parlsey."

Just so; there's no individuality about gardens nowadays. When you have seen one, you have, to all intents and purposes, seen the whole of them. They are all miserable copies one of another. Gardening has drifted into horticultural tailordom, and it is even gravely proposed to publish a yearly plate of the "latest fashions." It appears to me that cultivators will shortly improve nature off the face of the earth. I will give them a wrinkle—it has been in my mind for years. Get five thousand yards of Dundee canvas in red, blue, yellow colours, to suit pattern; procure plate of fashions for 1872; call out the housemaid and stable-boy; don't dig your beds—it is expensive, and quite unnecessary : lay your red, blue, yellow, &c., strips to pattern, and I venture to say you will have one of the most finished spectacles it is possible for the mind of man to conceive. So overcome am I with the advantages which my plan of

gardening offers, that I only await the consent of an interested friend to patent it. Let me enumerate its advantages: For a place of even small pretensions it would take £1,000 to be sunk in houses to keep up the usual stock of bedding plants. It would take, say £200, for gardeners' wages, looking after, and planting them. If I wished to go in for spring gardening, and something late after the bedders, it would cost at least another £200. Then I have plants to pay for, coals to pay for, additional frame room, propagating space; additional men to propagate, keep the plants through the winter, harden them off in spring, plant out and carefully protect thereafter, and to take up when their four months are over. Now, mark the magnificent results of my invention. Every item of this account is entirely saved; for the £20 for the canvas and the £1 for the plate of fashions will have been made up by odds and ends not mentioned in the list, and the remainder is done by myself and my two humble helpers in ten minutes. Can the objection to the bedding system be urged against mine, viz., that it is a blaze for two months, and blackness and darkness the remaining ten? Most certainly not. Talk about the seasons retarding vegetation and extending labour; I care not a fig for the seasons. Nothing can exceed the brilliancy of my red, yellow, and blue, &c., canvas, when well washed by the watery blast, which blew my neighbour's toil and expense to "smitherens" for a month, and when, after the storm, the sun shines through, my renovated beds present to the painter's eye and the poet's soul, a feast of the most ravishing effects and the most brilliant results. Am I twitted with providing this rich entertainment for the noble and the wealthy, I reply at once that, as in all strokes of true genius, every case is provided for. I vow, when I examine the increasing advantages of my astounding invention, I am lost in amazement at its magnificent advantages.

What, however, if my friend should object, as he has often done to former improvements confidentially mooted to him? He is a great Nature's advocate; and, to say the truth, my scheme is not very complimentary to her; in fact, she is, so to speak, entirely done without and ignored. But what of that? She is at all times capricious; and if I, by a stroke of unparalleled ingenuity, can remove her old, half-dead trunk, and substitute a sapling whose beauty and persistent loveliness is a delight from year's end to year's end, am I not entitled to the thanks of every discriminating individual? Clearly I am. Yet it is very likely my friend will disagree with me. If he does, he will, no doubt, treat me to the sixty-ninth repetition of his pocket-lecture about Nature. I know it well. This is how he commences: "Suppose a painter to be doing his best in his latest effort. A single tree is necessary for the foreground. Does he away and limn the scraggy thing at the corner of the street, or does he not rather try back in his memory, and in his portfolio, for the glorious sample of leaf and bough, and light and shade he came across in his woodland rambles? When he paints a fairy glen, does he go to the back-door to paint the gullet with the city's sewage pouring down? No; blindfolded he could lay his finger on the draught he made of the little northern ravine, with its trickling well and dewy ferns, that made heart and eye dance with delight at its marvellous beauty. He has travelled through the British Isles; he has been to Iceland, Norway, France, Spain, Italy, Egypt, even to Palestine, and everywhere his artist's eye and poetic soul have caught nature in a thousand of her loveliest and most enchanting forms. Here the quiet lake, there the majestic mountain piled in awful grandeur. In the morning a sunrise, in the evening a sunset; the 'wimplin' burnie,' the roaring cataract, the placid sea, the angry ocean, all furnish to his discerning eye and discriminating mind the pabulum that will one day place him among his country's greatest painters. He has painted scenes of lake views, but not one resembles another, although he might tell you that the sketch of each was nearly the same; that the little mountain lake he came upon in his Swiss tour had furnished him with rules for mountain, wood, and water effects ever since. But although he may vary these effects in numberless profusion, it never enters his head to portray a monstrosity in his 'wild' scenery. You are surprised, perhaps, to see that his trees are all of the orthodox cast; in fact, so plain are they in leaf and habit that you can tell them at once, even from a distance. Suppose we get him by the button-hole, and say to him in a confidential way, 'My dear fellow, you have really surpassed yourself in that woody scene. Couldn't you, just to light it up a little, have painted that front giant, say, with a white ground, yellow on the sunny side, as is natural, and blue will suit very well for the other and shaded side; the leaves of say a pretty pink; and have carried a broad band of golden gilt up the entire trunk to make it truly magnificent?'

"The oak tree with the white body, yellow and blue sides, and pink leaves, with gilt stripe in the middle, is, sir" (and here my friend looks wrathfully at me), "the present bedding system. Instead of the gardener of the present day being an artist, who studies

Nature, so that from every tree and flower, and hill and dale, he may cull ideas wherever to "mend" his plan—to "change it rather," from a dreary wilderness to an ever-pleasing and fruitful landscape, he is a miserable paper-hanger, upholsterer, and plasterer, with his ribbons and lines, his cow-muck banks, with their paltry house-leeks stuck in; he is a cross between extravagance and vulgarity. Let him take a hint from Mr. S. R. Hole and his parsley bed. We are being done to death with vulgarity. The gardener breaks his own back, and shortens his days, with the eating anxiety and care caused by the millions under his charge. Day by day his, say twelve, men are driven like horses to propagate, pot off, harden off, arrange, plant out, carefully tend, and pick over; then propagate again, and take in and winter, the hideous stock necessary under this exterminating system (to all concerned), and not to speak of the heavy and never-ending expense to the employer. This is all trying. Having had a surfeit of expensive novelties, with the results above stated, let us revert to the old style, and see what can be made of it, helped with such modern ideas as we may have picked up. Let us have all trees of beautiful and distinct forms; all shrubs remarkable for fine flowers or graceful growth or foliage. Let us have perennials from the tiniest to the largest, and as many as possible sweet-scented. Let us have as many species as possible of the grand foliage plants to be found in the hardy section; and with such adjuncts as have just been named, surely any gardener might produce striking landscape effects, very different from those attained by means of ordinary bedding plants. However I may have spoken, I do not blame the gardener, employer, or nurseryman personally; least of all the first; but as a body they have been leading each other for many years into the deepest quagmire of expense and vulgarity." This is about the substance, although not the length, of my friends production; and, notwithstanding the scheme I had propounded, I am afraid he has made me already a convert to his views.

W. W.

A GOOD STAKE FOR CARNATIONS, PICOTEES, &c.

NONE of the routine work of gardeners is of greater importance than staking, and the difficulty of getting it neatly and well done is often too evident in gardens. Even where there is time to rigorously attend to the staking, the beauty of the garden is often marred by the plants being tied into broom-like bundles.

The little invention here figured is intended to provide a stake which is at once cheap, unobtrusive, everlasting, and, if we may so speak, self-tying. The illustration shows it first by itself, as it is made for picotees, &c., by taking galvanised wire about one-twelfth of an inch thick (hard drawn), and twisting it in a long spiral wayabout

Fig. 1.

Fig. 2.

four times round a stiff straight piece of wire about a quarter of an inch thick (once round in about three inches), finishing with a sharper turn round the top about three-fourths of a revolution, and then cutting off, so as to leave half an inch of straight wire at the tip; the straight part at the bottom being about nine inches in length. Fig. 2 shows it applied to a picotee, and it is stuck in so deep that the top bud shall just rise above it. The plant is then wormed round so as to let it fall into a position in the middle of the spiral stick; and when the top is also slipped into its place it will be found as safe as if it were tied over so well, being supported by the bit of straight wire left for the purpose. A few yards away this stake is scarcely observed, so neat is it compared with ordinary sticks. Another good point is the freedom which it allows to the foliage and long hanging flower-stalks to fall away

from it if they wish; and, in addition, if the stem grows after it is applied—as it nearly always does—it slides up without making any ugly hitch in an attempt to push up against ties, as in the old way. A man might make a hundred in a single evening out of half-a-crown's worth of wire, and apply them to plants next day in less than half an hour.—A. D.

A PLEA FOR OUR HEATHS.

WHY are our native Heaths not more frequently grown than they are in grounds kept and arranged for pleasure? Why not have a Heathery as well as a Rockery or Fernery? There are spots in every place of any dimensions where Heaths would be useful, growing as they do where many things will not succeed. How to cover that ugly "bank" is often a matter of concern to those who possess such places. Attempts are sometimes made to clothe such a place with ferns; but if the bank is elevated and open, Heaths would be the right plants in the right place. They glory in such a spot—plenty of air, plenty of sun. It is astonishing what they will encounter and conquer, even in dry seasons. They send their roots down after moisture to a considerable depth. Even in stony soil poor they somehow get through the severest drought when once established. A bank of Heath in flower, with rocks jutting out here and there, is a sight which invariably commands attention. In strolling through a wood some time ago, I came upon broad masses of *Erica ciliaris* full of flower, and again suddenly upon what must have been acres of *E. cinerea*, to which a few straggling Firs here and there served as supports, thus forming cones of flower. This, thought I, affords a pleasure which our dazzling terrace-gardens do not give, and furnishes a sight which ought to be more frequently seen. I have also found bushes of *E. vagans* six feet through every way, forming huge balls of flower. But this is describing some of Nature's flower shows. The question is, how shall we copy her example in having such spots of beauty in dressed ground? It is of no use to go and offer battle to Nature, and rob her of her big plants, bring them home, and think the thing is done. No; we must, like her, begin with little plants; although we have seen Heaths grow in almost any soil from which lime is absent, and sometimes where it may be said there was no soil at all, yet it is best to make a little preparation for them in the way of excavating little cavities and filling up with peat or very rotten leaf-mould, mixed with loam. This will save time in getting the plants to a good size, and save trouble and attention, which want of preparation would incur. If the distance is not great, and the soil in which these plants grow naturally can be got, that is best for them, taking the surface off three inches deep. Do not by any means allow any plants to be put in with hard balls of soil about them; loosen it as much as possible, without damaging the roots, before planting, otherwise no water will penetrate, and they will consequently die. Almost any nurseryman could supply our native Heaths and their varieties at a cheap rate; some catalogue as many as fifty hardy kinds, beside the Mediterranean varieties.

HENRY MILLS.

Enys, Cornwall.

THE LIBRARY.

DARWIN'S "ORIGIN OF SPECIES."*

We have to record and to welcome the appearance of a new and cheap edition of this remarkable and most interesting book. It is needless to say anything in reference to its object now, as, since the appearance of the work originally, the chief ideas which it contains have been fully discussed. Few will deny (except perhaps those who discuss what they call "Darwinism," without having read the book, and such people are far from uncommon) that, even if they cannot go as far as the author and his more pronounced co-workers and disciples, the work has opened up a new and delightful field of thought and observation. On Mr. Darwin's labours we cannot do better than cite the opinion of Mr. I. Anderson-Henry, a well-known and very successful hybridizer of plants, who by no means adopts Mr. Darwin's views. It occurs in a paper read before the Botanical Society of Edinburgh:—

The various papers and publications given to science and the world in recent years by Darwin and others have directed the attention of all botanical observers of phenomena in that department to

* Darwin's "Origin of Species." Sixth and cheap edition. London: John Murray, Albemarle Street.

the changes which have been and may be effected on the existing species of plants; and those who reflect on the diversity of the vegetable kingdom as displayed in the grandeur of the various forms which compose the primeval forests of the torrid zone, or in the no less diversified but homelier forms of our temperate climes, must be attracted with the statement that, throughout all past time, change—slow but incessant—has passed on everything that now has life; insomuch, that we see no more the things which were in the things that do appear. So, at least holds Darwin, whose observations for general accuracy, so far as they are open to scrutiny, stand well the test of investigation; though beyond that limit they diverge, as he himself admits, into speculations which, however logically deduced, all of us are free to adopt or reject, as we are or are not convinced by them. Much, I am free to acknowledge, I believe of the Darwinian theory—more now than I once did. Yet, as I have been asked by a high authority (in reference to a paper which I read in March last), whether I adopted the Lamarckian view, which forms the germ, if not the basis, of the Darwinian doctrines, I reply unhesitatingly, No—not in their beginning or their ending—though where the latter is, Mr. Darwin is perhaps as much at sea as any one of us. But lop off that beginning and ending—all, lop it off as regards his views of the animal creation—and there remains in that great work, "The Origin of Species," a body of botanical philosophy, so well sustained by the author's own accurate observations and wonderful discoveries, that it constitutes, in my opinion, the most valuable contribution ever yet made to botanical science, and marks an epoch in its annals more brilliant than any yet attained. This is no inflated eulogy. For the last quarter of a century I have myself devoted every spare hour of my professional leisure, and for the last seven years (when free from professional yoke), my leisure almost entirely, to similar pursuits. And, as a humble labourer in the same field during all that time, I have some claim to be recognised as capable of forming an estimate of what has been discovered and achieved by Darwin, and given to the world in that great work, and in his scarcely less wonderful book "On the Fertilization of Orchids," and his papers read before the Linnean Society. He has not only accomplished great things by himself; but he has aroused attention, and stirred up other admirably qualified observers to extend his researches, and, it may be, has thus led the way to no less startling discoveries.

Nature has many mysteries to unfold. She has fixed rules, some so plain, that he who runs may read; and she has exceptions to these rules. Look at the wonderful provision she has made for the fertilization of orchids, and look at the no less marvellous modes she has adopted for the same end in the dimorphic forms of the genus *Primula*, and also in some forms of the genus *Linum*—of all which Darwin was the grand discoverer. I was myself almost a sceptic in the results obtained by him till I tested the statement he enunciated in the former genus by actual experiment, and found it true. Before he wrote, I had been myself at work among the species of the genus *Linum*, and while I found some of them tractable and open to self-fertilization, I found a disturbing element among others, for which I never could account, till I found it cleared up by Darwin in his dimorphic discovery. To a mind like his, ever alive to follow out by untiring research every perplexing cause which baffles the expected result, one discovery followed and perhaps suggested another, and it may be that the most brilliant of all yet awaits him. Let us follow in his wake; and though few are so constituted or so gifted as to attain to like successes, there is much for all to do. There is romance in the pursuit, and laurels to be gathered by every acute, industrious observer.

WAGES OF LABOURERS IN VARIOUS COUNTRIES.

The Hon. Edward Stanhope sends the *Times* the following statement, showing the comparative earnings of agricultural labourers in the principal countries of Europe, with the purchase-power of money and the usual diet, where it has been possible to ascertain these particulars. The statement is founded mainly upon the reports of her Majesty's representatives abroad on the Tenure of Land, and on the condition of the Industrial Classes in Foreign Countries 1869-70-71. Reference is also made to the appendix to the lecture of Mr. James Howard, M.P., on Continental Farming and Peasantry. For comparison, the rates of wages and diet in Great Britain and Ireland are appended. The table deals only with hired labourers, and avoids all mention of the small proprietors at home or abroad. One disadvantage in the way of the foreign workman is the number of holidays or village fêtes, which number in Russia from 30 to 100 during the year, in Austria at least 76, in Turkey 48, and which are very numerous in Belgium, Spain, and Switzerland:—

"AUSTRIA.—Wages—Galicia, 9d. a day in summer and 6d. in

winter; at harvest, 1s. to 1s. 2d.; Silesia, men, £4 a year; women, £3, with board and lodging; Moravia, 8d. to 1s. 4d. in summer, and 6d. to 10d. in winter (Dr. Fuchs, 1869). In 1867 the average wages were from £3 to £4 for men, or £1 to £3 for women, with board and lodging. It has since risen (Lyttton). Purchase-power.—Same as in England at Trieste; twenty-five per cent. less at Ragusa. Diet.—As a general rule, well fed (Lyttton).

BELGIUM.—Wages average 7d. to ls. 1d. a day for men, and 4½d. to 8d. for women, with extra at harvest (official 1862). From 1s. 2d. to 1s. 8d. for men, and from 8d. to 10½d. for women (Pakenham). Purchase-power.—Necessaries as dear, luxuries cheaper, clothes dearer, than in England (Consul Grattan). Diet.—Coffee adulterated with chicory, without milk or sugar; black or brown bread, butter, lard, vegetables, and fresh or salted pork. Very many have only potatoes with grease, bread, and chicory (Pakenham).

DENMARK.—Wages, 1s. 8d. to 1s. 8d. a day, or 5d. to 10d. with food. Beer and brandy at harvest. Hours of work, twelve to thirteen in summer, and daylight in winter (Strachey). Purchase-power.—An unmarried operative can barely live on 10s. 6d. a week (Strachey).

FRANCE.—Wages, 1s. 7d. a day in summer, or 1s. 3d. in winter; women, 10d. and 7d. (M. Leconteux). A farm labourer engaged by the year has £12 or £14 and his board, costing about as much (M. de Pimpin). Purchase-power.—No real difference, but on French mode of living twenty-five per cent. less (Vereker), fifteen per cent. more than in England (Hamond). Diet.—Soup made of pigs' lard or beef suet, vegetables, and bread porridge (Hamond).

GERMANY.—**PRUSSIA PROPER.**—Wages, 6d. to 1s. a day for men, and 5d. to 7d. for women, with house rent free, potato land, and medical attendance, or £3 to £4. 10s., and board, for men.

POMERANIA.—5ds. to 75s., or even 150s. a year, and board, with meat three or four times a week; food worth £10 a year.

RHINELAND.—In summer and 10d. in winter, with house rent free, or 1s. to 1s. 3d. without it. Hours of work twelve, or in harvest fourteen. Diet.—Porridge, milk, dried peats, potatoes, vegetables, and herrings. Meat on holidays. Such boarding valued at £9 to £13 (Harris-Gastrell).

SAXONY.—Wages, 1s. to 1s. 3d. for twelve hours; women 6d. to 9d. Diet.—Bread, butter, cheese, soup, vegetables, coffee, and beer. Meat only on holidays (Burnley).

BAVARIA.—Wages, 1s. 2½d. a day for men, and 11½d. for women on the average. Diet.—In south, meal with butter, fat, or milk, cabbages, and potatoes; in north, meat two or three times a week, instead of the meal and coffee (Fenton).

WURTEMBERG.—Wages, 1s. 2d. to 1s. 8d. a day, with food, or £5 or £6 with board and lodging in a farmhouse. The necessities of life cheaper, and the standard of living much lower. Diet.—Potatoes, rye bread, and cider; very little meat (Gordon).

ITALY.—Wages—Lombardy, 1s. to 1s. 7d. a day, without board; Bologna, 10d. to 1s. 5d.; Parma, 6d. to 10d.; Naples, 10d. to 1s. 3d. (Herries). This does not refer to the *métayers*. Purchase-power.—At Brindisi as fourteen to ten in England; at Naples as fourteen to eight. Diet.—Very little animal food, but principally macaroni, bread, fruit, vegetables, and wine.

NETHERLANDS.—Wages in Gelderland, 8d. to 10d. a day for men, and 6d. to 8d. for women, or £5 to £10 a year, with board for farm servants. Purchase-power.—Necessaries about as dear, luxuries much dearer. Diet.—Tea and coffee, black and brown bread, butter, vegetables, and fat; fish in season (Locock).

RUSSIA.—Wages, by the day 1s., by the month 7½d. a day, by the season 5½d. a day; at harvest 2s. a day; on well-managed estates they work from four a.m. to nine p.m., with three hours rest (Michell). Purchase-power.—One-half for natives, and for Englishmen one-third, cheaper than in England (Consul Stevens). Diet.—Cabbage, or mushroom soup, baked buckwheat eaten with milk, oil, or butter, and rye bread (Michell).

SPAIN.—Wages—Galicia, men, 12d. to 14d.; women, 7d. to 10d., or £4 to £6 with board, washing, and a suit of clothes; Murcia, 1s. 4d. a day without, or 8d. with board; Guipúzcoa, 1s. 2½d., or 8d. and food; women, 8d. to 10d.; Biscay, 1s. 8d.; women, 10d. to 1s.; Valencia, 1s. to 1s. 6d. Purchase-power.—Food far cheaper, but meat a luxury. Diet.—Bread, vegetables, and *gaspacho*—cold soup of slices of cucumber and bread steeped in vinegar and water (French).

SWEDEN.—Wages, for men, 7d. to 2s. 2d. in summer, and 3d. to 1s. 8d. in winter; for women, 4d. to 1s. 10d., and 2½d. to 1s. respectively; farm servants, with board, £3 to £8 (Gosling). Purchase-power.—Wages bear a greater proportion to the expenditure than in England (Jocelyn). Diet.—Potatoes, rye, oats, and barley; milk abundant; salt herrings, but no meat; beer (Gosling).

SWITZERLAND.—Wages, 10d. to 1s. 8d. in winter, and 1s. 8d. to 2d. 6d. in summer. In remote districts still less (M. Bovet). Working day generally reckoned at thirteen hours. Purchase-power:

Board for a man averages from 5s. 6d. to 7s. 3d. a week. Diet: Milk, coffee, cheese, potatoes, vegetables, and soup; meat rarely; wine and beer.

TURKEY.—Wages, 1s. 6d. a day, or £7 to £14 a year, with board and lodging ("Vinsu Moore"). Diet.—Brown bread of mixed grain, staved beans, leeks, and a little mutton.

ENGLAND.—Wages, for men, from 1s. 6d. to 2s. 9d. a day, averaging over 2s., with extra money for harvest and piece-work. Diet.—White bread, bacon, potatoes and vegetables, cheese, tea, coffee, and beer or cider. Milk and butter scarce. In the North a good deal more meat, especially for farm servants.

SCOTLAND.—Wages, 12s. to 15s. a week, being partly paid in kind, or £18 to £24 a year with food. Diet.—Oatmeal porridge, bread, potatoes, milk and butter, tea and coffee, a little bacon, but other meat rarely.

IRELAND.—Wages, 1s. to 1s. 8d. a day, or 6d. to 1s. with food. Diet.—Bread, potatoes, oatmeal, milk, whisky, and a little bacon."

THE INDOOR GARDEN.

CLIMBING FILMY FERNS.

THERE is no more beautiful or interesting example of cultivation than that of the climbing filmy ferns so successfully grown by Mr. James Backhouse at York. When at York in 1870 we had one of the beautiful specimens there photographed, and from this our illustration is engraved. It is impossible in an engraving to render full justice to the finely-divided texture and exquisite grace of these plants, which, when they become popular, will add quite a new charm to our hothouses and warm ferneries. The creeping species at York climb up

Trichomanes Laschnathianum.

imitation stems made in common porous flower-pot ware. On this, which in a moist atmosphere gets quickly covered with moss, they thrive apace. We are indebted for the following remarks on the essentials of the culture of filmy ferns to Mr. James Backhouse:—

The cultivation of the filmy ferns depends for success upon one or two very simple things, viz., perpetual humidity in the atmosphere, and a steady "medium" temperature—40° to 45° for the cool ones in winter (*i.e.*, for British, Chilian, and New Zealand species), and 55° to 65° in summer, and for the tropical species, 55° in winter to 70° in summer: As will be seen by these figures, extremes of heat and cold are always wrong, as the total annual variation should never exceed 20°, or at most 25° for the cool species, and 15° or 20° in the case of the warmer ones. Shade, which absolutely keeps off the sun's rays, and yet allows as much light as would exist in the open air when a cloud covers the sky, is requisite. These points "carried" and "kept," success may be considered certain. Sudden increase or decrease of either temperature or moisture is dangerous. Half-an-hour's sunshine in early spring may ruin "a year's work." Light vegetable soil, more or less mixed with white sand, is "the correct thing" for nearly all. The rhizomes should creep upon, or be above, the surface, the rootlets only penetrating the soil.

THE BETEL-NUT PALM.
(*ARECA CATECHU*.)

This Palm is grown in the Indian Archipelago for its seeds, which are chewed by the natives with lime and a leaf of *Piper Betel*, which is said to be intoxicating. In this country it is a beautiful palm, with spreading dark-green fronds resembling feathers. It has a clear, erect, and graceful stem, which in its native country rises to a height of upwards of

Pinang, or Betel-Nut Palm.

forty feet. It likes a moist climate, and does not grow freely in pots, except it has a great deal of heat and water. We are indebted to Mr. Bickmore's interesting work, "Travels in the Eastern Archipelago," published by Mr. Murray, of Albemarle Street, for our excellent illustration of this fine palm.

J. CROUCHER.

MARECHAL NIEL ROSE CULTURE.

I HAVE just seen a remarkably fine example of the culture of this noble rose with Mr. Merryweather in his nursery at Southwell, Notts. It was as simple as successful. Imagine the roof of a span-roofed house, originally prepared for a viney I believe, lightly shaded, not with vine leaves, but with the no less beautiful foliage of this lovely rose; and picture also a whole galaxy of golden buds and blooms, like those we have

all so much admired at our flower shows, drooping gracefully from all parts of the roof. Three plants cover the roof of the house in all its parts, and from it Mr. Merryweather cuts every day from seventeen to twenty-four dozen of fine blooms; and yet the house was so full of its beautiful golden treasures that it looked as if no one had ever ventured to cut a bloom therein. This case is very suggestive of the grand qualities of Maréchal Niel as a roof plant. Trained over the roof, as at Mr. Merryweather's, there is nothing to prevent one using the house just as if it did not contain this precious gold-bearer. The shade given by the foliage is so light that the cultivation of most kinds of plants is quite practicable beneath. I was reminded of Mr. George Paul's good suggestion of using the Maréchal for training over the roof of the camellia house, than which plan nothing could be more desirable.

W. R.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

A Sweet-Scented Palm.—A whole acre of mignonette would not emit more perfume than a single plant of the Fan Palm of the Rio Negro (*Mauritia carana*). In approaching one of these plants through the thick forest, the sense of hearing would, perhaps, give the first notice of its proximity, from the merry hum of winged insects, which its scented flowers had drawn together to feast on the honey, and to transport the pollen of the male to the female plants; for it is chiefly dioecious species of palms that have such sweet flowers.—R. SPRUCE.

A Simple Mode of Growing the Huntsman's Cup (*Sarcocenia purpurea*).—Get healthy, fresh young plants, and pot them in peat now with a few lumps of crocks or a few lumps of peat at bottom, the last the best. Use thirty-two or forty-eight sized pots, according to the size of the plants, and then place them on a light shelf in a greenhouse or pit, near the glass with full light in either case. Put a saucer under each, filling it with water, and keeping it so, not otherwise attending to the plants, except perhaps to syringe them when the other inmates of the house or pit receive that attention. In that way you will have dwarf, healthy, and stumpy specimens of this most interesting plant, that will, after a year or two's growth, bear comparison with any in existence.—H. V.

Half-Hardy Palms.—It will be found that the dwarfer and harder palms of comparatively cool regions will prove capital ornaments for our houses at all times. Their leathery texture enables them to stand a dry atmosphere that would kill ordinary thin-leaved plants in no time, while their exquisite grace and beauty of form place them above all other vegetable ornaments for house decoration. We strongly advise any readers who have an opportunity of securing some of them in a young state to do so, as nothing can be more useful either in house, open garden in summer, or conservatory in winter. Among the best obtainable kinds are *Chamaerops humilis*, the dwarf fan palm of the south of Europe, *C. excelsa*, of America; *Corypha australis*, one of the best, very hardy; *Cocos coronata* and *flexuosa*; *Latania borbonica*, *Thrinax elegans*, and a good many other kinds, are available.—H. V.

THE PROPAGATOR.

ON PURE HYBRIDIZATION, OR CROSSING DISTINCT SPECIES OF PLANTS.

BY ISAAC ANDERSON-HENRY, ESQ., F.L.S.

(Continued from page 507.)

From my readers I respectfully claim the same kind indulgence which Darwin has shown to the testimony he has had to deal with, in judging of the views I have offered, and am now to offer, on the experiments which I mean to lay before you. But ere I enter upon them, it is necessary to premise, especially as regards that form of dimorphism which occurs among many plants in the Linnaean classes from *Pentandria* up to *Decandria*—in having very generally one if not two pairs of stamens shorter than the other stamens in the same flower. And the same dimorphic form often occurs in even a more marked degree in many plants of the class *Tetrandria*. It is also the distinctive character of the two orders of *Didynamia* to have two long and two short stamens.

As observed in my former paper, it is now seventeen years since my attention was drawn to the *long* and *short* stamens, but to the latter more particularly in some muling operations there alluded to, where, by using them, I crossed that large species of *rhododendron*, *R. cinnamomeum*, on the pigmy *Rhodothamnus chamaecistus*. I refer to these short stamens again, as the means by which I succeeded in effecting some extraordinary crosses which, I confidently believe, but for their use and my improving a propitious time, would have been utterly impracticable. As I have said, I at first worked only with short stamens. These I use in all cases where I wish to cross a large on a small species. I have now found that the converse holds, and use the long stamens where I wish to cross a small on a

large species. In all extremes I use the longest or shortest pair of stamens as the case demands. The short pair is generally well distanced by the others—the longest pair is often not just so much in advance. There is often an intermediate pair of short stamens, which in cases less extreme are exceedingly serviceable, but there are seldom such intermediates among the long ones. My reason for the use of these short, intermediate, and long stamens is intelligible enough. If I wish to cross a large on a small species, the smallest-grained pollen being in the short stamens, I take the pollen of these stamens of the large plant as best fitted to pass down the tubes through the stigma to fertilize the ovules of the smaller species, and so effect the cross on it; and so, *ceteris paribus*, with respect to the other forms.

I shall restrict the instances I am now to cite to the last few years, noticing first,—

CASES OF CROSSING WITH SHORT STAMENS.

The first cross I shall notice is one already alluded to, viz., Rhododendron *virgatum* with my own hybrid rhododendron B (*R. ciliatum* crossed on *R. Edgeworthii*); and as this cross is memorable and instructive in several points of view, it is proper to give you its history. On April 20, 1864, I find from my note-book that "I took off all expanded blooms of *R. virgatum* and removed the stamens from all unopened ones on the plant, there being none left for self-fertilization; done in fine sunshine—west wind—with three short anthers of 'B'—i.e., the hybrid male, being the identical cross which produced Veitch's rhododendron, Princess Alice. Of this cross I ripened four capsules of seed, which I sowed on January 28, 1865, and, with some failures, got up by December that year seven nice healthy plants, all of which, however, save one, I lost by an accident. That one plant is now setting for bloom—not at the axis, as the female parent (*R. virgatum*) generally shows, but at the extremities of the shoots, as in the male (*R. ciliatum* crossed by *R. Edgeworthii*). But, as I have had occasion to observe already, the type in all else is more that of the female than of the male parent. By the mother's side this plant is a hybrid, by the father's it is a mongrel, and yet it has a fair share of vigour in it. As in its sexual aspect, so in its height, it is that of the mother. A few cilia are noticeable on its leaves, but it has none of the tomentose or dense hairiness of the male parent; and so in this also it partakes most of the glabrous foliage of the mother. Again, this doubly-crossed plant, and the crosses which produced it—all extreme—show how such crossing may hasten on the reproductive or flowering state. Never in all my experience have I seen or heard of rhododendrons offering bloom at two years of age. I have rhododendrons now fifteen years from seed which have never shown the slightest tendency that way, though ten and twelve years I would consider about the mean at which they attain their flowering condition. If by such crosses the like precocity can be generally secured, practical florists may turn them to some account in their profession. You will please observe that I am now dealing with hard-wooded shrubs, where there is in general more fixity of structure and habit, than in those on which the physiologists I have cited have chiefly experimented, and which are less liable to be modified by the manifold influences which affect the more pliant and shorter lived herbaceous genera.

2nd. The next cross in the rhododendron tribe effected by the short stamens to which I would direct attention is very recent, and one with which I took the utmost pains to prevent miscarriage. The beautiful *R. jasminiflorum* of Java, with its delicious perfume and its long tubular five-lobed flowers, of snowy whiteness, so like *Erica Aitonii*, so like, too, in form and fragrance, the sweet-scented *Jasmine*, and so unlike all its own congeners, is the subject of it; and as I regard this cross of some scientific as well as of some practical value, I shall offer no apology for giving you particulars. I made it the subject of many attempted crosses by many of its own tribe—all of which failed except two, which, by the way, afford a good illustration of what I alluded to in my former paper of the sympathies of plants, and perhaps, too, of natural selection, though whether it be in the mode which Darwin regards as leading to diversity of species I cannot positively assert, yet I think it is worthy of his consideration. While it rejected so many of its legitimate brethren of the rhododendron tribe pure and simple, I was somewhat surprised that it took kindly with my hybrid B already noticed—i.e., *R. ciliatum* crossed by *R. Edgeworthii*—a hybrid of the first degree, having large flowers of three inches diameter, perfumed, and also of snowy whiteness. After the bloom had been long emasculated, on April 17, 1867, I effected the cross with the short anthers of the hybrid B. The cross took admirably—the seed-pod swelled, and was pulled fully ripe about 12th July last. On the 15th of that month I sowed the seeds. For the purpose of comparison, I sowed a pod of its own plain native seeds which I had gathered previously, and had, in fact, sown it some ten or twelve days before I sowed the cross. These are both now up. While the native seeds have produced a fair show of feeble plants,

the crossed seeds have come up in more than double the number of plants, doubly vigorous in growth and habit, and with leaves so much larger than those of the normal form as to remove all doubt about the verity of the cross.

3rd. The next illustration I have to give you is of a small-foliated Indian azalea, eighteen inches high, which I crossed with the tall and robust shaggy-foliated Rhododendron *Edgeworthii*. Two things more unlike in every feature from which to effect a union can hardly be imagined. Yet, with the short anthers—and it was with the very shortest I could find on *R. Edgeworthii* that I effected it—the cross, after careful emasculation, was done on 6th May last. The seed-pod swelled to its due dimensions, and, appearing to be ripe, I cut a slice off it, and sowed the seeds so early as the 13th, and the residue on 28th, September last, and I have now got up one or two plants. If I shall be so lucky as to bring it to maturity, the progeny of this cross (one never before accomplished perhaps) should be a sweet-scented azalea, having a rose variegation like the female parent, a novelty in its tribe; for though the *Azalea sinensis* has been crossed by rhododendrons, I am not aware of any authentic cross, or cross of any kind, between the rhododendrons and this proper Indian azalea.

4th. I have still further a cross of the same nature, between another Indian azalea and Rhododendron *jasminiflorum*, the latter being again the seed-bearer; and I here refer to it mainly as showing another tendency of this rhododendron towards natural selection, or rather perhaps of sympathy between it and remote species, if not genera, for the azaleas have till lately been regarded as a separate tribe from the rhododendrons. The cross was effected in August last, when it again rejected its more natural allies, and formed a union with the Indian azalea, a late rose-coloured spotted variety, a seedling of my own raising. The seed-pod of this cross is now at maturity.

5th. But I have now to call your attention to a cross in this same family bearing on Darwin's doctrine of natural selection, or of sympathy, in a still more remarkable manner, which I effected last summer between that most gorgeous of all the rhododendron tribe—namely, the lovely white, large-flowering, sweet-scented *R. Aucklandi* of Dr. Hooker otherwise, *R. Griffithii*—and an Indian azalea, the latter being the seed-bearer. I made the cross on two separate days on two separate blooms, carefully emasculated some time before; and on the same azalea I tried other crosses with several of the rhododendron tribe, viz., with a fine form of *R. arboreum*, *R. Edgeworthii* pure, and the above hybrid seedling B (*R. ciliatum* × *R. Edgeworthii*). But while every one of these failed, the crosses by *R. Aucklandi*, which were effected respectively on the 30th April and 1st May, took most kindly. Both pods swelled; and the seed-pods, though green, appeared to be sufficiently ripe when I pulled them. I counted the seeds in one of these pods, and found them to be about 324, all finely formed, but I fear, too green to vegetate freely, though some which I sowed appear to be coming up. I cannot vouch for this cross being effected with the shortest stamens, for the stamens with which I effected it were kindly sent to me from another source, as I did not myself possess the male plant; but as I invariably select the shortest for such crosses, my firm belief is that I had so selected these in this instance, and I had a plentiful supply of all lengths to choose from. In the above cases of crossing a small with a large species, I hold firmly by the opinion that but for the use of the short stamens I could not have succeeded. I have few recorded instances of having extended my experiments with them far into other families. I certainly tried the pelargonium in a plant I had of the beautiful white-flowered Madame Vaucher. I fertilized a bloom with its two shortest stamens, which, however, were very little shorter than the remaining ones; and, from the three seeds which came of it I raised two fine plants, far more compact and somewhat dwarfer in habit than the parent, having the flowers equally fine, and elegantly thrown up above the plant. But the short stamens of this section of the Geraniaceae are very little shorter than the others, and I therefore cannot rely much on the results as establishing the hypothesis I contended for in my former paper—namely, that where all other things are equal, a cross or simple fertilization with the short stamens tends to dwarf the progeny—to my belief in which, however, I still adhere. The instances I have given support this other hypothesis, that by their use you may cross a large on a small kindred species, a result which, without them, you might not effect.

(To be continued.)

Kew Gardens and the Proposed Military Station at Richmond.—We learn from the *Surrey Comet* that a house-to-house canvass of the tradesmen of Richmond has resulted in establishing the fact that a very large majority of them are in favour of Mr. Cardwell's proposal to make the town a military station. It may be so; we do not care to dispute it; but what we would submit is that Mr. Cardwell and the shopkeepers of Richmond are not the only

parties to be consulted. It seems to us that if the matter is to go by popular vote, London has a right to be asked its opinion. We have been legislating for the last two or three years for the preservation of the few pleasant spots accessible to us after our day's work or on occasional half-holidays, and we have done so in the interest of the metropolis as a whole. Hampstead Heath and Wimbledon Common have been saved, not for the benefit of the few hundreds or thousands of persons who live in their immediate neighbourhood, but for the sake of the three millions who crowd the metropolitan area. The question for Mr. Cardwell to consider is not whether the Richmond publicans and tobacconists may profit by having soldiers quartered in their vicinity, as it is more than likely they would, but whether Londoners ought to be deprived (as they will be virtually deprived) of one of their most agreeable places of resort, when, as he himself has stated, no necessity for the deprivation exists. Richmond Park and Kew Gardens are national property, and the ratepayers of Richmond, even if they be as unanimous as the local paper represents them to be, have no pretence of right to determine whether they shall retain their present quietude and propriety or be overrun by half-trained recruits. Whatever may be said about the aristocratic associations of the Star and Garter and the Park, the gardens at Kew belong to the people, in the most popular sense of the word, and nobody who has seen the hundreds of working-men's families who visit them alike for pleasure and instruction every fine Sunday afternoon, and marked the propriety with which they conduct themselves, would wish to see their recreation interfered with.

THE GARDEN IN THE HOUSE.

A MOST CHARMING WINDOW PLANT.

WHAT can it be? A Fuchsia? Well, that is charming; but it is not about the Fuchsia I would now write. The Geranium, a rare window plant that has been, from first to last, from the oldest Cape species down to the newer plain or variegated striped zonal—all have found their way to the window. And they have done good service in sweetening and adorning our homes. But it is not the Geranium. Well, I have seen windows made glorious with Cacti, especially *C. speciosus* and *speciosissimus*; and as succulents are once more the rage, perhaps it may be one of these. No; it is a simple hardy plant, so beautiful that it deserves a place in every boudoir, and so cheap and easily grown that it might light up with a gleam of beauty even a garret window. Everybody admires, loves it; and what is more, everyone might grow it. It is the lovely Forget-me-Not—*Myosotis dissitiflora*, the earliest and the most beautiful of all the Forget-me-Nots. For some years I have found that no hardy plant is more grateful for the shelter of glass during the winter and early spring than the Forget-me-Not. By putting up a few tufts of it in November, and placing them in a sunny frame or window, they will be in full flower in January or February. In passing through Bury St. Edmund's the other day I was much pleased to see it in full beauty in two windows in the street. If in two, why not in a thousand? The plant can be increased by means of division, cuttings, or seeds to any extent. By giving it a little morsel of ground, any number of tufts, say six inches across, fully charged with flower-buds, may be had ready in November. Pot a few in any soil in four-inch pots, and place them in the window. Those not potted will come in for succession in March, and will continue the blooming season till the end of May. And if a few plants are divided late, and the first flowering ones in pots are planted out as soon as they have done blooming, a succession of Forget-me-Nots in windows or gardens may be enjoyed all the year round. But the greatest merit belonging to the Forget-me-Not is its early flowering. Long before Fuchsias, Geraniums, or almost any other plants are half awake from the semi-torpor of the winter's cold, the Forget-me-Not is already in sky-blue robes. Are any in doubt, let them try; and if it does not answer all I have said and more, they have either got the wrong variety or do not know how to grow it.

ON CHOOSING FLOWERS FOR DECORATING VASES.

I HOPE that "W." will kindly supplement his remarks on this subject by giving a few instances of good and bad selections, with the flowers best suited for variously formed vases. The latter is a point very much overlooked in floral arrangements. The self-same things are often used for all sorts of vases, large and small, short or tall, narrow or wide, cornucopias or glass baskets. This is a great mistake. There ought to be a certain fitness between the form and size of the casket and jewel—the flower-holder and the flowers. One

great difficulty is to obtain flowers of different colours to harmonise in form. Take, for instance, such a charmingly sweet flower as Mandevilla sauvoleens. How difficult to find a match for its waxy blossoms in red, unless the *Lapageria rosca* or *Tacsonia von Volxemii* happen to be in flower at the same time. When Pelargoniums or other flowers are used instead of these, the incongruity of shape mars the effect; and so with many others. What flowers, for instance, unless it be some of the Hoyas, will match the bunches of Stephanotis floribunda? We want red, pink, or blue bunches of similar make to bring out the colour without marring the symmetry of form, if I may so express it. Perhaps Ixoras fit in with the Stephanotis better than most flowers. This difficulty of harmonising form, and the tendency of mixtures to run into sameness, has made me a convert to the utmost simplicity, inasmuch as I believe that, as far as possible, every vase should be furnished with but one flower, and fringed with its own leaves. The Maiden-hair monotony of finishing has become as intolerable as the universal flower mixture so often served up in dining and drawing rooms with little judgment and less taste. But enough, and more than enough, for the present. I began by asking for examples of what to choose and avoid, and then with rare inconsistency—I was almost tempted to write a harder word—have gone on to give some and censure others. Still, I am sure we shall be grateful to "W." for filling a few vases for us as they ought to be filled.

D. T. F.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 446)

DRAINAGE.

WITH regard to drainage: the hole or holes in the pot should be in the bottom at the lowest part, and no water should sink to any part where it cannot run off; therefore the sides of the pot should have an equable inclination towards the bottom, which should be concave, to facilitate the egress of the water. Care should also be taken that the potter, in making the holes, leaves nothing inside to form a rim round them. The next condition is that the ball may easily and without injury be removed from the pot as soon as it has become so filled with roots as to form a solid mass. To secure this desideratum, the sides of the pot inside should slope evenly from the upper edge to the bottom. In the ordinary kind of flower-pot the sides do not slope evenly, but at the bottom there is a slight incline towards the drainage-hole in the middle. Underneath is a rim to enable the pot to stand on a hollow bottom. Where several holes are made in the sides at the bottom, the bottom may be somewhat arched in shape. When there is no rim at the bottom, the pot should be placed on pieces of sherd or wood, so as to prevent it from standing flat on the ground. In the case of a vase which I employ, the foot serves for a saucer, and the upper part is made to lift on and off, in order to empty the foot of water when necessary. The sides of the vase may be curved at pleasure, but on the inside they must diminish gradually in width, in order to allow of the ball being taken out uninjured.

FLOWER-POTS AND VASES.

All other flower-pots or vases should be made on these principles: The material should be a porous, well-baked clay, or may even be of wood. Glazing, or painting the pots with oil-paint, is not to be recommended; yet of the two, the paint is not so injurious, as the glazing completely hinders the percolation of water and air. For the same reason pots of earthenware, porcelain, iron, zinc, &c., are not proper. Wherever, as in plant-cases, flower-stands, &c., zinc trays are used for holding plants, the bottom should be concave, and pierced with numerous holes. Freshly-burnt, unglazed, new clay flower-pots when first used absorb a considerable quantity of moisture, so that the plants must be watered more frequently until the sides of the pot are completely saturated, or, better still, leave the pots immersed in water for an hour before they are used. Old pots, which have been long in use, are sometimes covered with mould or moss, which hinders the percolation of the air. It will be very beneficial to the health of the plants, if the outside of the pots is frequently cleaned; and in no case should an old flower-pot be used for a fresh plant without being thoroughly cleansed. Lastly, the size of the pot is a matter of importance. It should, of course, be always adapted to that of the plant. To sum up the preceding observations—a plant may receive more water, in proportion as the

drainage of the pot is free and its sides porous, as it is new and clean, as the size of the ball is small, when compared with the plant, and as it is filled with roots.

REPOTTING.

In transplantaing, a part or the whole of the roots in the ball are usually removed, the outer layer of soil being seldom penetrated by the roots. It is now planted in a new, porous pot, in which the outer layer of soil speedily comes under the influence of the dry air; but so long as no young roots are protruded from the old ball, the outer layer will remain tolerably moist. Attention must therefore at first be given to the ball, and not to the surrounding layer of soil. Accordingly the soil should be raised around the edge of the pot, so that the flow of water may be directed to the ball. But as soon as young roots are sent into the surrounding soil, it should receive most attention, and should not be watered before it has arrived at a proper degree of dryness. This period of root-forming after transplanting is a time when no water should be given, unless it is absolutely necessary and signs of dryness make themselves manifest, otherwise the newly-formed roots soon perish and the plant becomes sickly. This has been long known to the practical gardener; and certain plants, such as Camellias, which at other seasons must be watered plentifully, must be kept dry after being transplanted. The explanation of this we believe to be, first, so long as no young roots are sent out of the old ball into the new soil, the moisture of the latter is only given off as the old ball requires it, and so no harm is done. Secondly, a very concentrated and rich food is suddenly applied to the young roots when they penetrate the surrounding soil, and this of course will be all the richer for being watered. Thirdly, it is a fact that the formation of roots goes on all the more rapidly the more they are brought into contact with the percolating air, as, for instance, in loose sandy soil; while in heavy stiff soil the process is much slower. Now the drier the soil is allowed to remain, the more easily will the air percolate through it, and the stronger and more abundant will be the formation of the roots in consequence.

DEFICIENT NOURISHMENT.

The writer has observed that want of nourishment induces plants to send out more roots in loose soil, so that by the increased number they may obtain more food, but that in loose but well manured soils, and in heavy, stiff, unmanured ones, root-formation was very feeble, so that he has arrived at the conclusion that the production of roots in loose soils is due to the action of the atmosphere. The position and the season of the year exercise a very great influence on the necessity for frequent or unfrequent watering. Plants will require more water in proportion as the air is dry and warm, the position exposed, and the weather clear and bright. A plant standing in an exposed pot will require more water than if the pot were plunged in sand, earth, or moss. Where the evaporation from the pot is increased by the action of dry air, or of the sun, the pot may be shaded with a board, or pots in a window may be placed up to the rim in boxes of sand, earth, or moss, which in bright, warm weather should be kept well moistened. Plants grown in rooms will require less water in autumn, when the temperature of the room ranges from 60° to 66°, than at other periods of the year, when the dryness of the outer air, at a lower temperature, produces a corresponding dryness in the room. At those seasons of the year when the rooms are not heated and are well ventilated, the watering of the plants must be regulated by the temperature of the outer air. In bright, hot weather, when the air is dry, plants in rooms require most water; but the lower the outside temperature, and the moister the air in consequence of frequent rains, or the short days of autumn, the less water will be required. In winter, the supply of water should be diminished according to the coldness of the weather. The necessity for watering must also be regulated by the health and state of vegetation of the plants. All diseases of plants, which declare themselves by the partial drying up of the shoots, a feeble growth, the yellow tinge of the leaves, or their falling off while still green, are intimately connected with injury to the roots, which absorb water, and with it nutriment. As a man when ill requires less food, and must be restored by proper dieting, so it is with plants. The more serious the disease the less nutriment is required to be conveyed to them by means of watering, and in this case the ball should be carefully

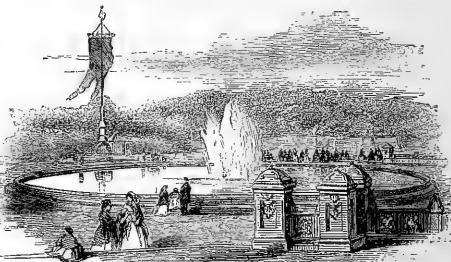

examined as to its state of dryness before any water is given. On the other hand, the more healthy a plant is, and the more richly covered with leaves, the greater is its need of water, as every leaf is employed in elaborating the food derived from the water, and in transpiration. A plant in full vegetation not only requires a rich supply of food, but transpires from its tender young leaves much more water than from the firm old ones. Therefore the more luxuriant the growth of the plant, the greater will be its need of water; but when plants are in a state of rest, and no new growth is being made, the less will be their need of water, and the more cautiously must it be given. Deciduous plants in a state of rest require least.—*From the German of Dr. Regel.*

PUBLIC GARDENS.

THE CENTRAL PARK AT NEW YORK.

No public park yet made has cost so much money as this, and we are bound to say that the result is not unworthy of the vast expenditure. In point of design, extent, planting, &c., it is equal, and in many respects superior, to anything of the kind in existence. It is not a park in which gaudy temporary colour effects are produced at great expense to last for a few months and then perish, but in which all the really important and permanent features of a public garden have been developed with rare taste and ability. Large lawns of green, extensive plantations, a splendid series of roads, beautiful naturally disposed lakes, and immense reservoirs of pure

Portion of Lower Terrace, with Fountain, in Central Park, New York.

water for the supply of the city, occupy the greater part of its surface; but there are so many minor details of interest that it is only by the aid of detailed description, and a good many illustrations, that we can hope to give any just idea of this highly creditable national work. We are the more desirous to do this, as much of the work done in the Central Park seems well worthy of imitation wherever public gardens are created.

To us the park seemed, however, to show certain highly objectionable faults, which we will proceed at once to describe. The history of gardening is to a great extent the history of its sufferings at the hands of architects, and, to a smaller extent, from sculptors. These have invariably used it to display their own work, not nature's. Hence Versailles, with its miles of crumbling balustrade, and many other hideous scenes which we have been accustomed to call gardens. If architects had not our habitations, public buildings, and cities on which, and in which, to display their skill, one would not mind allowing their free scope in a national park. But few will dispute that it is nature, and not useless, objectless, second-rate, and costly architecture, we want in our public gardens. In the Central Park as much money has been spent on useless work of this kind as would have created another noble park without such needless embellishments.

In this country elaborate terraced-gardens are justified by the often far-fetched and groundless reason that the proximity of their sites to the house made this treatment necessary. Here a costly terraced-garden has been made in the middle of the park, away from any building; an example which we trust

may not be imitated. It is very well done, but quite out of place.

Of the costly terrace the following explains the most favourable American view, and hints clearly enough at the result of allowing architects to work their own way in a public garden, with which they really should have no connection:—

"The terrace is at present incomplete, and indeed it must be many years before the design, as it exists on paper, can be fully carried

Drinking Fountain in Central Park, New York.

out, because it includes full length statues, as well as busts, of distinguished Americans, which it is intended to place upon the large pedestals that are now covered with temporary ornamental caps. The commissioners have done wisely in making no attempt whatever as yet to procure statues for these places, and it ought not to be done until there is ample means to secure the best work possible in America. First-rate statues are as yet hardly to be got for money here, though we believe that they will be produced in good time; but until they can be had it is best to wait; for a second-rate

Bridge over Arm of Lake in Central Park, New York.

statue is not to be endured. If one statue is found fit to be placed upon the terrace in a generation, we shall think we are getting on very well indeed. But so long as the pedestals want their heroes, so long the terrace will be incomplete, and people will be half justified in saying that it "looks squat." This, however, is a difficulty which it was not possible for the architects to avoid. They

probably never expected nor intended that the park would be completed in a single decade, nor in two. Indeed, until every tree upon it is fully grown, the effect they had in view at the beginning cannot be realized. We must consider the terrace, then, as an incomplete architectural composition."

In connection with this may be named the useless bridges which span the roads of the park in numerous places. There was, of course, occasion for bridges in various places; and very tastefully designed and gracefully clothed ones span parts of the ornamental water, of one of which we give an illustration. But the bridges we object to are those, the building of which arose from a desire to construct separate routes for pedestrians and equestrians, instead of allowing the roads to cross each other where necessary, as in the far more crowded parks of London and Paris. Hence different levels, and many well-built and costly bridges, such as that shown herewith, have been con-

Bridge in Central Park, New York.

structed. All these bridges, too, are constructed in the best manner, and are well designed, but they are nevertheless utterly needless.

(To be continued.)

THE ROYAL GARDENS, K.E.W.

THE PALMS.

THESE "princes of the vegetable kingdom," as they are justly called, are well represented at Kew, though unfortunately the great Palm House there is too large for the maintenance of the proper degree of heat and moisture that is required for their successful cultivation. They are therefore distributed in different houses. In the Palm House properly so called are fine examples of the Fan Palm (*Sabal umbraculifera*), Sugar Palm (*Arenga saccharifera*), *Arecia alba*, *sapida*, and *Bauerii*; the Wine Palm (*Caryota urens*), *C. Cummingsii*, *Seaforthia elegans*, *Phoenix reclinata* and *sylvestris*, *Livistona humilis*, *inermis*, and *chiensis*; *Cocos flexuosa* and *Trithrinax aculeata*. These are planted out, and so noble an appearance do they present that, were it not for the paved walks that traverse the house, one might fancy oneself in a tropical forest. Most of these Palms rise to a height of from forty to sixty feet; and such kinds as *Sabal umbraculifera*, *Arecia Bauerii* and *sapida*, and *Caryota Cummingsii* produce seeds freely. At the south end of the house is a mass of *Rhapis flabelliformis*, and a very elegant species of *Areca* from Lord Howe's Island.

In tubs or in pots in this house are large plants of *Martinezia caryotaeifolia*, *Attaleas*, *Phoenix*, *Caryotas*, *Diplothemium*, *Astrocaryum*, *Hyophorbe*, *Calamus*, *Chametrops*, *Ceroxylon*, *Thrinax*, *Euterpe*, and *Elaeis*, varying from twelve to twenty feet in height; also many smaller plants belonging to various genera. When it is seen how much better those planted out thrive compared with those in pots, it seems a pity that more planting space is not afforded.

The best view of the Palms in this house is obtained from the gallery, from which each can be seen separately, and an idea obtained of what the whole would be if room were allowed them for free development. Thus looked down upon, their dignity of port becomes apparent. Judging from the

excellent condition of those planted out, it is evident that a regular state of the medium in which the roots run has much to do with success, and it also indicates that a Palm enjoys more rather than less heat than that which it gets in its native country. Were this not the case, we should not have *Sabal umbraculifera* (from the West Indies), *Livistona chinensis*, *Cocos flexuosa* (from Brazil), and *Arecia Bauerii* (from Norfolk Island), all in the same bed, and each equally healthy. The beautiful coral-like inflorescence of *Arecia Bauerii*, which is produced just below the lowest frond, annually attests the fact that it is quite at home. The *Sabal umbraculifera*, furnished with gigantic fronds, and producing abundance of seeds (annually nearly one thousand), confirms the same fact. Its associate, the *Wine Palm*, too, is in every way excellent. *Phoenix reclinata* resembles more than anything else with which I can compare it a gigantic fountain.

The collection of *Chamadorea*s is accommodated in a house near the principal entrance, where this genus is well represented. Its specialities are *C. Sartori*, *Ernesti-Augusti*, *crucifolia*, *Martiana elegans*, and *Arenbergiana*. These, though growing as they do here, under the dense shade of tree ferns and other fine-foliated plants, luxuriate, and produce flowers regularly; but they seldom produce seeds, unless artificially fertilized. In the centre of the newly-erected range of glass, as well as in the Victoria House, are some of the tenderer species of Palms, such as *Geonomas*; among which, the best are *G. Martiana*, *Ghiesbrechtiana*, and *Schottiana*. There may also be found *Stevensonia grandiflora*, *Verschaffeltia splendida*, and *Pritchardia pacifica*, three of the noblest-foliated Palms with which we are acquainted.

The *Cocoa-Nut Palm* is likewise in this house. It is fond of heat and moisture, and has succeeded but indifferently at Kew, where large plants have often died on account of the want of proper means of securing those conditions so essential to success. The *Cocoa-Nut Palm* is, without doubt, a very elegant plant for the centre of a large stove, rising up as it does with such dignity and grace. A plant of it at *Sion* has perfected fruit twice, and from what I saw of it the other day, under the skilful management of Mr. Woodbridge, it may be expected to bring forth many more. It is interesting to notice the way in which the nuts germinate, which is as follows:—Simultaneously with the advance of the germ outwards, inside is formed a sponge-like mass, which is at first much crumpled up, but by a gradual unfolding it softens the hard albumen by a process similar to that of the action of the gastric juice in animals, and gradually takes the whole up until the shell is cleared as clean as though scraped with a knife. By the time the albumen is exhausted, the sponge is fully developed, after which it gradually decays. The plant having now done what may be termed sucking, has to exist by means of its roots. A similar process goes on in all Palms, though in a less degree.

There also will be found representatives of the African *Raphias* and the *Doum Palm* of Egypt, lately described in your pages by Professor Owen, as well as many young plants of *Calamus*, and other introductions of recent date. We frequently read of *Calami* climbing to enormous heights, and we have often thought that if one or two were planted in a water-tank, they might be induced to show the public some of their natural modes of growth.

Specimen plants of *Chamærops Fortunei* and *humilis*, and *Jubaea spectabilis*, must be looked for in the new temperate house, in which an attempt was made to grow the lovely *Seaforthia elegans*, *Livistona australis*, and *Phoenix dactylifera*; but the winters in this house were too cold for them. Altogether, the collection of Palms at Kew consists of some 260 species.

Some have wondered why Palms have not been placed out of doors during summer. I, for one, should be sorry to see them spoiled by such treatment. A Palm out of doors in this climate looks, as a rule, a picture of misery, except, perhaps, on the very quietest and warmest of days.

J. CROUCHER.

[As in an early number we shall publish a view and sections of the great Palm House and great Temperate House at Kew, drawn and engraved expressly for THE GARDEN, we this week devote a page to sections, showing the comparative sizes of these two remarkable structures.]

GARDEN DESTROYERS.

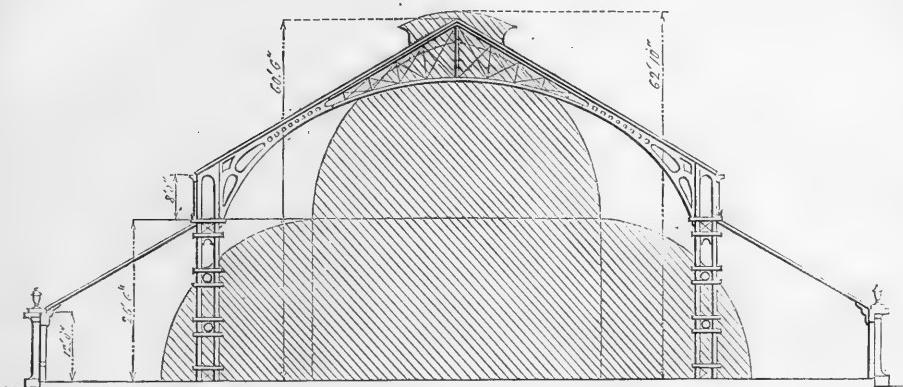

"WORMS."

[THE following, by Mr. G. A. Sala, refers to the caterpillars which have been so successfully fought by the English sparrows introduced to New York some years ago.]

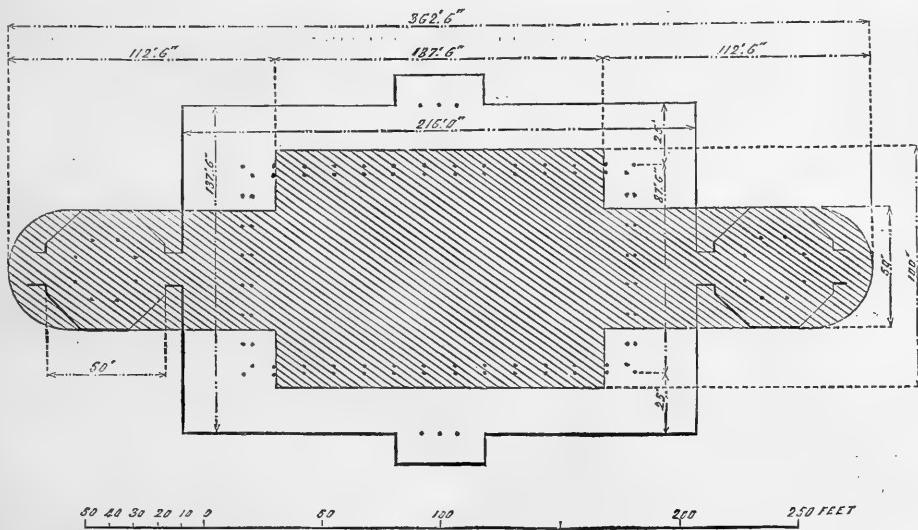

I was taking my walks abroad in Fifth Avenue, one summer's morn, meaning harm to no man, and with my heart full of sweet and placid feelings towards the United States. Suddenly I saw, advancing towards me, with fierce and rapid strides, an old lady. Now I am not afraid of ladies. This was, nevertheless, a very fearsome old lady to look upon. She was tall and wore no crinoline, and was crowned with a coal-scuttle bonnet. She had spectacles, also, and a very hard hickory-looking face beneath them. "This is an old lady from New England," I mused. "I see it all. She is from the State of Massachusetts. Residence East Buffum, profession widow, sectarian proclivities Heterodox Congregationalist." . . . I drew aside to allow this respectable but formidable female to pass; but to pass me was apparently not her aim. She meant mischief. Her eyes were inflamed with ire. Her lips moved at though in wrath. She held in one woollen-gloved hand a monstrous gingham umbrella; and with it she made as though to strike me down. She brandished this weapon of offence, this gingham Excalibur, above her head. She swung it to the right and the left . . .

She delivered the carte and the tierce and the reason demonstrative. She was clearly cunning of fence; and I thought I would see her blessed ere I fought with her. Her umbrella was, at last, within an inch of my nose. The hair of my flesh stood up. This old lady had evidently sworn to have my blood. Conscience makes cowards of all. But who was she? A Woman's Rights Convention delegate? A Black Republican? A manufacturer of chewing tobacco? A spiritualist medium? or an abolitionist lecturer? I had made up my mind for the worst, and was preparing either to fly or to cast myself at the feet of the vengeful old lady, and sue for mercy. "Transatlantic female," I was on the point of saying, "spare me!" . . . when the old lady rushed by me, still wildly waving her umbrella, but, with singular clemency, forbearing to knock my head off. And, looking back, I beheld her still urging on her wild career down Fifth Avenue, towards Tenth Street, brandishing her gingham all the way. Was she mad? Was she in a spiritual ecstasy, and speeding from a Revival? No, a hasty remark she made as she passed me at once explained the mystery of her proceedings. In a tone of dolorous agony she cried, "Oh, them Worms!"

Yes, those worms. They are the bane, the scourge, the nuisance, which, in the merry month of June, make a man's life a torment to him. The side walks of the streets of New York, faithful to their Dutch origin, are bordered with trees, principally limes and elms. In joyous June, when they are in full leaf, and their verdure has not been burnt up by the white heat of the summer sun, they are refreshingly umbrageous and look very pretty. But these trees are, one and all, infested by a horrible little reptile, known commonly as the "measuring worm," the "canker worm," or the "pacemaggot," but which, according to scientific authorities, has quite as much right to be called the "geometer," the "arpenteur," or the "hindrometer." It is of a dusky olive in hue, with a tawny head and a pea-green tail. It is about as long as a bit of string, and as big as a piece of chalk—say, the length of the middle joint of your little finger affords an apter standard of measurement. I don't know whether it has any eyes; but, when touched, a hideous green matter exudes from it. This worm swings by an almost imperceptible cord or filament from the branches of the highest trees, as of the lowliest shrubs. As you walk along the street, myriads of these worms are hanging motionless in the air. Suddenly they bob against your nose, they slide down your shirt collar, they enter your eye and sit on your lid. Open your mouth, and a worm slides down your throat. They light on your hands and your feet. A lady comes home from walking with her parasol tasseled, and the hem of her dress fringed, by these beastly worms. When they have minched their fill of the young leaves of the trees, they spin out of their own depraved bodies a slack rope of gluten; and down this aerial bridge they slide till they are within a distance of five feet from the earth. There they ruminate, till, gorged with vegetable dirt, these green leeches tumble down on the pavement, where they wriggle and wallow, and, after a time, I trust, die. The flagstones are so speckled with surfeited worms, that, on the finest and most cloudless afternoon, you may fancy it is just beginning to rain. As I have said, they specially affect to perform their Blondin and Leotard performances on a level with the faces of human beings walking erect, and the only way to

Sections of Palm House and Temperate House at Kew; the shaded portion shows the Palm House.

Ground Plans of the Palm House and Temperate House at Kew; the shaded portion showing the Palm House.

prevent their choking or blinding you is to arm yourself with a stick or an umbrella, and slash them away as you travel. The old lady I had met was evidently, and of old, aware of the worms, and of the means to combat them. Hence her violent and apparently hostile demonstrations with the umbrella.

These detestable creatures are no mere petty nuisance. They are destroying the finest trees in the streets of New York. You might take them to be pipe-layers, or log-rollers, or lobbyists, or members of a municipal "ring," so speedily and so completely do they devour every green thing. Like every other social nuisance, the worms have their friends, and one enthusiastic student of natural history writes to the papers to claim for them "a certain amount of brains, or at least of instinct." He watched, it seems, a flock of birds light upon a tree full of worms. The reptiles, knowing full well what the intent of these early birds must be, hastily "skedaddled" down their air-ladders, whence, like the showman's kangaroo who took refuge down his own throat, they doubtless (if worms can cachinate) derisively guffawed at their baffled pursuers. The birds flew away, and then the worms went back to gobble up more leaves. The strangest circumstance about these diminutive "cusses" is that their appearance in New York is a comparative novelty. Ten years ago they were unknown, and they are rarely seen in the streets of the New England towns, which are bordered by the most beautiful trees. Are they emigrants, I wonder? Did they land at Castle Garden? And, again, it has been remarked that by a grotesque coincidence, the worms and the barrel-organs come out together. You seldom see these "Alfred le Measurers" before the end of May, you rarely hear an organ before the beginning of June. By this time the first are squirming, and the last are grinding all day long. . . . In a month or so they will cast their slough of dusky clive, and blunder about the world and the gas-burners as the large uncouth moths which, from the loose white, flowery pollen with which their wings are covered, are known as "millers."

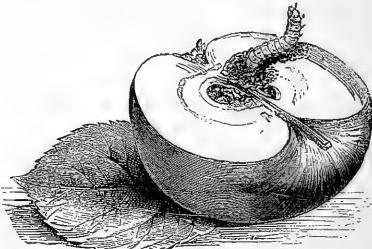

THE APPLE MAGGOT.

It is difficult to exaggerate the amount of injury caused by the apple grub on the continent of Europe, in England, and in the United States of North America. With a sagacious eye to self-interest, the apple-growers of Normandy actually, however, make a profit of its doings; they dry the grubby windfalls, and sell them to us under the name of Normandy pippins—and really very good they are when properly soaked and steered with sugar and lemon peel. The moth itself is a beautiful little creature—it is, indeed, the most beautiful of the beautiful tribe to which it belongs; yet, from its habits not being known, it is seldom seen in the moth state, and the apple-grower knows no more than the man in the moon to what cause he is indebted for his basketfuls of worm-eaten windfalls in the stillest weather. To find the moth in the daytime, the trunks of the apple trees should be carefully looked over; or, if your orchard be surrounded with a wooden fence, the moth may often be found sitting against it, with its pretty wings neatly folded round its body, which is three-eighths of an inch in length, and the wings are three-quarters of an inch in their expansion; the head and thorax are brown; the body, where covered by the hind wings, is paler brown, with a silvery gloss; the fore wings are of that colour which the Germans well express by the compound word grey-brown; they are delicately barred with dark purple transverse lines, and have on the hind margin a large dark blotch, and within this another blotch almost circular, and bordered with scales of a glittering fiery copper-colour. Towards evening—in fact, at sunset—the moth begins to move, and may then be seen hovering about the little apples, which by the time it leaves the chrysalis (the middle of June) are well kuit, and consequently fit for the reception of the eggs, which it generally lays in the eye of the apple, one only in each. This is effected by introducing its ovipositor between the leaves of the calyx, which, closing over the eye, forms a tent that effectually shields the egg from the inclemency of the weather or any other casualty. The act of oviposition is not, however, always confined to the eye. When the apple stands with the eye uppermost, I believe this is invariably the case; but when it hangs eye downwards, as though regarding the earth, the other end of the apple is used as a receptacle for the egg, which is then dropped into the cavity surrounding the foot-stalk. Neither is this the only alternative the moth possesses, for its egg may sometimes be found glued to the rosy cheek of the Quarenden—an apple which seems to be a favourite with our Carpocampa. I have not, however, found a single worm-eaten apple in which the grub had entered from the cheek—a fact that leads me to suppose that eggs so deposited must miserably perish.

As soon as the egg hatches, the little grub gnaws a hole in the rind of the apple, and buries itself in the substance; and it is

worthy of remark that the rind, as if to afford every facility to the destroyer, is thinner in the eye than in any other part, and consequently more easily pierced. The apple most commonly attacked is the Codling, a large early sort, which ripens in July and August. The grub, controlled by an unvarying instinct, eats into the apple obliquely towards the centre, thus avoiding the core and pips so essential to the apple's growth; at first it makes but slow progress, being little bigger than a thread, but after a fortnight its size and operations have much increased. Up to this period the grub has availed itself of the very restricted gallery it has made in its devouring career, as a channel through which to force its excrement; and this may always be observed in a little brown heap or mass, either concealed by the leaves of the calyx or around the base of the foot-stalk, according as the egg has been laid at the eye-end or stalk-end of the apple.

But when it has eaten half-way down the apple, and the position of the hole at the top, if the apple continues upright or nearly so, is inconvenient for this purpose, another communication with the outer air becomes requisite; and it must be constructed so as to allow the power of gravity to assist in keeping it clear. It is accordingly made directly downwards towards the part of the apple which is lowest, and thus the trouble of thrusting the pellets upwards through the eye of the apple is avoided, and a constant admission given to a supply of air without any labour. The hole now made is not, however, sufficiently open for an observer to gain by its means any knowledge of what is going on within; this is only to be obtained by cutting open a number of apples as they gradually advance towards ripeness. The hole is, however, very easily seen, from its always having adhering to it on the outside an accumulation of little masses of excrement which have been thrust through. Having completed this work, and having reached the core, the grub turns

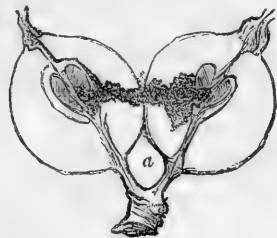

The Apple Maggot.—Section of Apple, showing Grub at work.

towards the cheek of the apple, and makes a third gallery, through which he eventually makes his exit, but not at present; for as soon as he has thus made sure of a means of escape he returns towards the centre of the apple, where he feeds at his leisure. When within a few days of being full-fed, he for the first time enters the core through a round hole gnawed in the hard, horny substance which always separates the pips from the pulp of the fruit, and the destroyer now finds himself in that spacious chamber which apples generally, and coolings in particular, always possess in their centre. From this time he eats only the pips, never again tasting the more common pulp which hitherto had satisfied his unsophisticated palate; nor nothing less than the highly flavoured aromatic kernels will suit his tooth, and on these for a few days he feasts in luxury. Somehow or other, the pips of an apple are connected with its growth, as the heart of an animal with its life; injure the heart, an animal dies; injure the pips, an apple falls. Whether the fall of his house gives the tenant warning to quit I cannot say, but quit he does, and that almost immediately; he leaves the core, crawls along his lateral gallery, the mouth of which, before nearly closed, he now gnaws into a smooth round hole, which will permit him free passage without hurting his fat, soft, round body; then out he comes, and for the first time in his life finds himself in the open air. He now wanders about on the ground till he finds the stem of an apple tree; up this he climbs, and hides himself in some nice little crack in the bark.

Such is the usual mode of proceeding; but I must notice a deviation from this mode. I have said that the moth, in the selection of a nidius for its egg, exhibits a preference for the early varieties of apples; but when these are not at hand it by no means denies itself the agreeable duty of billeting its destructive progeny on others. Still in the later kinds it very often meets with this difficulty: the apples

at this early period are much smaller, and a single apple is insufficient for the requirements of a single grub; so the moth, before laying its egg, judiciously selects a cluster of two, three, or four apples which are touching one another, so that, having worked its will on one of these, it can pass into the next through a hole in the cheek which it has made for this especial purpose; and, curiously enough, the extruded excrement serves as glue or cement to fasten two apples together like Siamese twins. In nine cases out of ten the grub contents himself with a single apple, never leaving it until he is full-fed.

Having now followed the grub until he is full-fed, it seems desirable to describe him entomologically; it has taken him three or four weeks to eat up to his full stature. The body consists of twelve

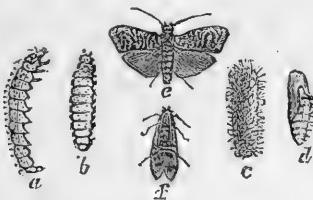

The Apple Maggot: *a*. Section of two apples joined together by the passing of the grub from one to the other.

segments besides the head, which is obtusely triangular, shining, and nearly black; the body is dingy white, with the slightest possible tinge of pink, except on the second and thirteenth segments, the backs of both of which are nearly black. It should here be observed that entomologists now properly consider the head as the first segment—hence the first segment of the body is the second segment of the insect; it is needful to bear this in mind, or some numerical confusion may occur in counting. Every segment of the body after the second has eight very small black warts, and these are arranged somewhat in pairs, and each wart emits a slender hair or bristle, which are too small and fine to be represented in a woodcut; the very pale colour of the body, and likewise the black warts, are more observable before the grub has quite attained its full size, after which period the colour of the body is slightly darker, and the warts are less distinct.

I ought here to remark, that the fall of the apple, the exit of the grub, and his wandering to a place of security, usually take place in the night-time.

When safely ensconced in the "nice little crack in the bark" I have already described, he remains without stirring for a day or two,

The Apple Grub viewed sideways, and distended by being killed in spirits, *a*; back view, *b*; the cocoon, *c*; the chrysalis, *d*; the moth with wings expanded, *e*; the same with wings folded, *f*.

as if to rest himself after the uncommon fatigue of a two yards' march; then gnaws away the bark a little, in order to get further in out of the way of observation; and having made a smooth chamber big enough for his wants, he spins a beautiful little cocoon or case, and within this changes to a chrysalis, which may be described as of a mahogany-brown colour, and as having on each segment of the body a transverse double series of minute warts; these, although so small, are rough to the touch, and may be distinctly felt by passing the finger along the back of the chrysalis. The length of time that elapses between the spinning of the cocoon and the transformation

from a grub to a chrysalis does not seem to be very constant, for I have found the grubs unchanged even as late as March. Be this as it may, it is quite certain that the creature, whether changed or unchanged, remains in the cocoon eight or nine months of the year and always during the winter months.

It is difficult, perhaps unwise, to express an opinion as to the particular design in the economy of nature which decrees that one animal shall either prey on or be preyed on by another. But two conclusions are inevitable; first, that the tomits, now so abundant in our cider counties, must inevitably perish were it not for the oak galls, and the hosts of apple grubs which have sprung up in the crevices of the bark, and which these active birds are hunting for during every moment of our short winter days; and, secondly, that without the assistance of the tomits the apple crop would be entirely destroyed by this irrepressible insect. Many a proprietor of garden or orchard in Herefordshire, Worcestershire, or Devonshire will contend that the tomits must be killed because they peck holes in the apples and pears just above the insertion of the stalk—a fact that cannot be denied, an act which cannot be defended; the blue-headed tomits in particular, if he have any conscience at all, must plead guilty to its commission; but gentlemen will find that in exactly in the same ratio as they diminish the number of their tomits so do they increase that of their worm-eaten windfalls.

To myself there is no sight more pleasing than a little bluecap searching every crack and cranny in the trunk of an apple tree for the cocoons of the apple grub; his excessive, his indomitable industry, the sharpness of his sight, the knowing manner in which he turns his head on one side the better to peer into the crevices, the drollery of his attitudes, infinitely surpassing those of gymnast or acrobat, and his merriment although perhaps unmusical note—all commend him to my affection, and indeed to my protection where I can possibly extend it; but almost every apple-grower of my acquaintance prefers worm-eaten apples to blue-headed tomits, and I find it impossible to overcome this preference.

Supposing, however, that our little chrysalis escaped the prying eyes of the bluecap; supposing no such ill fortune betide him as to be transferred from his carefully-selected retreat to the crop of the little bird—then by the middle of June the chrysalis has become a moth, and is again on the wing and hovering round the young apples on a midsummer evening as before.

"Is there no remedy but the tomits?" asks some devoted enemy of the titmouse race. Yes, a partial one. By burning weeds in your gardens at this time of year you may drive away this little moth. If you have trees the crops of which you value, make a smoking (mind, not a blazing) fire under each. It will put you to some inconvenience if your garden be near your house, but the apples thus saved will repay you for that. Then again you may do as some recommend—pick every apple that the grub has attacked. This is indeed a radical cure, but who can accomplish it? After all, Nature's remedy is by far the best; for the tomits will serve you without giving you any trouble, and simply for their own gratification. And then again, supposing you are possessed of an orchard (mind, this remedy will not do for a garden), turn in your pigs; nothing is more agreeable to the porcine community than crunching a windfall. It is proverbial that a pig always delights in going the wrong way; and I verily believe they like these windfalls all the better from a conviction that they are taking what they ought not—their silly little eyes twinkle with delight as they utter their complaining grunt over each crisp mouthful. Thus the pigs are fed, and the grubs are destroyed before they have left the stall where they were fattened.

E. Newman, in "Field."

BIRDS IN GARDENS.

This is, as one of your correspondents truly observes, a sore point in many establishments. Farmers have of late cried out loudly against the over-preservation of game, and undoubtedly much good has resulted to them from a free and temperate discussion of that subject; why, therefore, should not gardeners ventilate their grievances respecting the over-preservation of such birds as are destructive to seeds, buds, fruit, &c.? In places where there is a standing order that not a bird must be killed nor an egg destroyed the gardener is often placed in a difficult position; for, no matter however careful and vigilant he may be, if birds are present in undue numbers, they will mar his hopes and destroy the fruits of his labours in spite of all he can do to prevent them. I have several times tried to net up large standard cherry trees so as to preserve the fruit until ripe, but have never succeeded, for the simple reason, that if no way was left for the birds to get inside, they very soon made one, and after that a good many more, by breaking the meshes of the net, be it new or old.

As a garden destroyer, the blackbird may be placed in the front

rank, for he is not only a great thief but a great glutton, and very daring; he has also a well deserved reputation for wariness and cunning, for he will run on the ground under cover of anything that may be on it, until out of gunshot, and then he skims quickly over the wall and into the bushes, chattering defiance as he goes. In dietary matters his taste seems to be pretty correct, but his habits are profligate; although he invariably attacks the best first, he does not trouble himself to make a clean job of one fruit before he begins on another, but gorges away right and left till he has spoiled the lot and filled himself until he can hardly rise from the spot. If he cannot get soft fruit, hard will do; no matter how hard it is, his bill is strong and his digestion good, and when the supply of fruit fails, he will take to worms and such things; but then he is hard up —these are his last resource.

ARCHITECTURE AND FOLIAGE AT WILHELMA, WURTEMBERG.

STUTTGART some few years ago was one of the most picturesque of small German capitals. Its Alten Schloss Platz, a spacious area, was enclosed by buildings whose quaint

lions of the vicinity. The gardens are laid out upon a partially geometrical plan, in more or less accordance with the form and character of the building. But the unpleasant formal result which might have been expected from this system of planting has been relieved from its most objectionable characteristics by allowing the growth of the trees and shrubs to assume their natural forms and dimensions; so that, while the arrangement is based upon a well-defined and even "formal" plan, which, near a large building, has many advantages over unmeaning tortuosities, the objectionable element of mere formality is overcome by the graceful irregularity and varying forms of the luxuriant foliage. The end attainable by this means is well worthy of careful consideration, for it is of great value in garden aesthetics.

Mere uniformity is of high value as a foundation, but requires to be elevated into symmetry, which is a thing of far higher character and importance than the bare duplicate repetition of any given set of absolute forms. For instance, in a group of buildings one wing may be made to harmonise perfectly with another, not by mere repetition, but by the introduction of objects

The Chateau and Grounds of Wilhelma, Wurtemburg.

architecture formed the delight of travelling artists in search of subjects for pallet and pencil. The ancient Schloss of the Electors occupied one entire side of the Platz, and from it diverged the principal streets, almost as rich as the Platz in interesting specimens of mediæval architecture; but modern improvements, all in the direction of convenience, cleanliness, and improved ventilation, have played sad havoc with many of the most picturesque features of the place. Each of the main streets of Stuttgart leads to one or other of the gates of the little Wurtemburg capital, and through the opening of nearly every one of them a view is obtained of vine-planted hills, which form a delightful termination to the vista. Many of those rocky vineyards yield wines of various qualities and considerable excellence, which, at no distant period, are destined to be better known in England than they are at present. Not more than a mile or two from the city is the domain of Wilhelma, the fine modern chateau of which, with its pretty conservatories and outbuildings, is one of the

and forms of corresponding values. Say, on one side a low massive tower is the main feature, while on the other a slender and lofty turret is made to balance that effect harmoniously, without the necessity of resorting to the unimaginative and poverty-stricken resource of repeating the low tower; and thus symmetry, instead of mere uniformity, is attained. In the same way, by judicious planting, the effect of masses of trees and shrubs, which, in the ground plan, are geometric reflexes of each other, may be made to produce similar varieties of effect without destroying their harmony. A towering and slender Deodar, for instance, being made to balance the effect of a dark mass of evergreen oak, in a manner precisely analogous to that of the low square tower and the accumulating minaret above alluded to.

These principles are well shown in the engraving of the Wilhelma structures and gardens, which serves to illustrate these remarks. The buildings, though pleasing, have, unfortunately, somewhat of that fantastic cast which distinguishes modern

German architecture, which is in a state of active, but exceedingly indecisive, transition. Whether it shall become Gothic, or Spanish-Saracenic, or Italian *resorgimenti*, or whether some national style shall evolve itself from the chaos of decomposed architectural atoms which are at present being jumbled together in the struggle after progress, it is difficult to say. German critics dream very fondly of a "Gothic of the future," as in the art of music the adherents of Richard Wagner boldly assert the coming advent of a "Music of the future." But just at present a little fog of confusion, both in idea and performance, somewhat obscures the distant prospect.

THE ARBORETUM.

FINE TREES OUT OF PLACE.

BY JAMES BARNES.

How often in our rambles do we observe trees planted in situations in nearly every garden and pleasure-ground that would almost cause one to imagine that little thought or consideration had been previously given as to the amount of space they would require for extending their growth, or the size to which they would ultimately attain. Everywhere do we find fine old Cedars, Larches, Cypress, evergreen Oaks, and even Poplars, Yews, Horse Chestnuts, Elms, and other large and ornamental trees, planted closely to old castles, mansions, halls, &c.; and still such misplacement is continued. Neither is this always the gardener's fault; for a lady or gentleman may purchase in a pot a plant of some newly-introduced tree, and, without consulting anybody, choose some conspicuous spot for the reception and future development of their little favourite. The gardener is then informed of their decision, and although he may remonstrate, his endeavours to frustrate their purpose often fail. This, therefore, is frequently the reason why we find stately and handsome trees planted so near mansion houses. During their infancy, all goes on well; but as they grow older, they increase in stature, as a matter of course; and, if not removed, they ultimately attain dimensions which quite unsuit them for the situations they occupy, sometimes darkening the house, and at others obstructing a free view of the distant landscape.

Where it is desired to have choice trees grown to advantage, a piece of deep, well-prepared ground should be selected purposely for them, in what may be termed an arboretum, where, when once planted, they should be allowed to remain uninterfered with.

When the Sequoia (*Wellingtonia*) gigantea was first introduced into this country, a number of them was placed under my charge, and, with careful treatment and regular and large shifts, to my great satisfaction, they soon made fine luxuriant plants. Proud of my success, I wished to provide them with a permanent situation where they would be well sheltered, have plenty of room, and enjoy a considerable depth of good soil; and with that object in view I consulted my employer about them, when I learned with astonishment that the place fixed upon for their future development was where they now stand, viz.—in a situation exposed to the sea, on the poorest ground on the estate—a solid bed of gravel! I determined, however, to make the best of such adverse circumstances; I gave each tree a space of sixty feet, trenched the station on which it was to stand forty feet in diameter, and enriched it with surface soil and whatever other suitable material I could obtain, thoroughly incorporating the whole and fashioning it into a gradually sloping mound five feet high in the middle. At the time of planting, a railway was to have been made through an adjoining field, the turfy surface of which I intended to secure, for the purpose of filling up the hollows between the trees to a height of six or eight feet, thus converting their present mounds into little valleys; but in this I was afterwards disappointed. In planting, the centre of each mound was cast out, and a load of good open healthy soil was introduced, in which the plants were inserted. They were then mulched, and the operation was finished by placing a rustic cage six feet in diameter around each young tree. Thus treated, and kept free from weeds, they grew most luxuriantly, and safely weathered the cutting north and north-east winds of the severe winter of 1860-61, and also those of the winter of 1864-65, with the exception of a slight searing on the windward side, from which they completely recovered the following summer.

In the arboretum one tree was planted and did remarkably well, when, owing to an addition of seven or eight acres of new ground being made, it, together with others, had to be removed. I then planted it on a spot filled up with many hundreds of cartloads of healthy old bank soil mixed with turf, thus forming a depth of eight feet of excellent soil, in which it will find room to grow and luxuriate

for the next five hundred years at least; there it remains still, a noble example of what may be expected of this tree when planted under favourable circumstances.

These Sequoias (*Wellingtonias*) have for several years produced cones, both male and female, and from their seeds have been obtained young plants. Immediately I discovered the male catkins, and found them in a fit state, I had a few of the female cones fertilized; these quickly swelled, and from their enlarged form could easily be distinguished from others even from a distance. When full grown the seed cones are about the size of a walnut, and in shape something between that of the cones of *Cupressus macrocarpa* and of *Celrus Deodara*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Preserving Stakes.—Some few years ago, I had some stakes for the nursery made of pine inch-boards, three inches wide, sharpened to a point, and then boiled for a short time in a solution of blue vitriol, and they are lying around in the field now as sound as the day they were made; while other stakes, coal tarred, do not last much longer than when left without it.—*A. Starke*, in "Cultivator and Country Gentleman."

Golden Yews.—Persons interested in these effective shrubs, or those who are yet unacquainted with the splendid effects well-developed specimens produce, would do well to see the fine old examples in Mr. Anthony Waterer's nursery at Woking. In summer they assume their richest tints. A good specimen, seen amidst the ordinary verdure of our evergreens, is something not to be forgotten.

The Tulip Tree.—A few days ago we saw a tulip tree about eighty feet high, in Surrey, and one which was much crowded up by other trees. This reminds us of what few seem to be aware, that this tree, which endures the hardest frosts of the American winter, is considered the largest tree of the Eastern or older States of America, often reaching a hundred feet high and six feet in diameter. Specimens in North Carolina have been measured thirty feet, and even more, in circumference.

Movement of the Sap.—The following example destroys the generally admitted rule, "that the sap rises by the albumen and descends between that and the bark to form the cambium." Our illustration is an elm of about nineteen inches in diameter, near the base of which four inches in width of bark have been stripped all round. Notwithstanding that, and also that the operation took place towards the end of December 1870, the tree does not seem to have suffered in the least, and has shot forth very well. It is therefore certain that the movement of the sap, both up and down, must have been by the centre of the tree.

Mistletoe Bearing Oak.—There is a fine old oak with mistletoe growing on it in Lord Sondes' Park at Lees Court, Kent. I saw it for the first time in 1867. I do not know if it was known before that time that the parasite was growing upon it in five different places. I have been to look at it to-day (April 2nd), and I see that some ruthless hands have cut away the two largest pieces since I last saw it, so that there are now only three pieces left. There are hundreds of oaks of all sizes growing around it, from saplings to hoary-headed fellows that have stood the tear and wear of time for centuries, but on none can I find the parasite growing, except on the solitary one just-named.—J. PINK, *The Gardens, Lees Court*.

GARDENING FOR MAY.

THE INDOOR GARDEN.

BY T. BAINES, SOUTHGATE.

Conservatory.—In order to prolong the flowering season of such plants as are in bloom here, it will now be necessary to attend carefully to shading during the middle of the day in sunny weather. Scrim, a fabric made of flax, is much the best and cheapest shading material in the end. It outlasts considerably any other material I have ever tried. The finest quality of it will break the sun's rays without excluding too much light. Roof climbers will now require regular attention to keep them from becoming an entangled mass. The system of allowing the whole roof to become covered, as is frequently done, is objectionable. It excludes too much light from the plants underneath, especially in dull weather; it also spoils the general effect, which is much enhanced by confining climbers to something like one-fourth of the roof space, and leaving them to hang down gracefully at intervals; yet in this too much uniformity should be avoided, by allowing some to hang lower than others. Let every means be employed to keep them free from insects, more especially scale. Azaleas that are brought into bloom in other structures for removal to the conservatory, will be benefited by sprinklings overhead with the syringe every afternoon until their flowers are fully expanded; they should also be shaded, especially the high-coloured varieties. They must likewise be well attended to with water, as during the development of their flowers there is a much greater drain upon the roots than at any other time, and if allowed to become dry the flowers suffer as well as the growth for

the ensuing year. Geraniums and Calceolarias that are throwing up flower trusses should be encouraged by means of liquid manure, not too strong, especially in the case of Geraniums, or it causes them to run too much to leaf. Fumigate regularly, and not too severely. Fuchsias stake, stop, and tie. Closely examine them to see that they do not suffer from aphides or red spider, as either quickly spoils them. Cockscombs, Balsams, Achimenes, and Hydrangeas should be well attended to, as these, with the plants previously mentioned, will be the principal things to be depended on during the following two months, when there is a much greater scarcity of flowering plants than during early spring. Chrysanthemums that have filled the small pots they at present occupy, should be at once potted into their flowering pots; from eight to twelve inch pots, according to the sizes the plants are required, will be found large enough for general use. If fine flowers are wanted, stop the shoots during this month, but not later. A dozen really good blooms on a plant of the large-flowered varieties are preferable to three times the number of starvelings often met with. Plunge them at once in their summer quarters in ashes, which will prevent worms from getting into the pots, and will keep their roots at a much more equable temperature than when not plunged. The effect of rapid change in the temperature of the soil in an ordinary plant pot when not plunged is not sufficiently considered; during bright weather the effect of the sun's rays acting upon the pot raises the earth heat in an unnatural degree, and therefore the cold chill of even our summer nights causes a corresponding reaction. The first batch of Primulas and Cinerarias will now require potting into thumb pots, using good loam, well enriched with rotten dung and leaf mould for the purpose, mixed with a little clean sand; place the plants in a somewhat close pit or frame; shade them from bright sun, and attend to them well with water. Pot off all cuttings struck of Euphorbias, Hydrangeas, and Poinsettias, placing them in a growing temperature near the glass, so as to insure short, stout growth. Rhynchospermum jasminoides is a useful conservatory plant, its fragrant white flowers rendering it a general favourite. It is a plant of easy management, requiring the temperature of a viney or intermediate house during its growing season. The different varieties of Kalosanthus will now be fast showing flower, and will be benefited by weak manure water. Get them properly tied before the shoots get too heavy. They are useful decorative plants for summer. Now is a good time to propagate them; they strike freely in loam or peat, with an admixture of a little sand, giving very little water until they are rooted. Tie out Achimenes as they advance in growth, giving them all the light possible, so as to induce a stout, blooming habit. A good number of the oldest plants of scarlet and pink Geraniums should be selected for keeping up the conservatory display during the summer and autumn; and a batch of the scarlet Pelargonium Vesuvius should be potted into six-inch pots and turned out of doors, where they will be fully exposed during the summer to the full sun. With these it is not size that is required, but a thoroughly matured growth that will ensure their flowering freely when subjected to heat for winter decoration.

Stove.—Allamandas in pots that have not made a sufficient number of shoots should have their branches wound round the trellis on which they are trained, bringing the points of the shoots down towards the top of the pot; this will have the effect of causing them to break freely, which growth will show bloom before it has advanced far. All stove plants that flower from the current season's wood will be benefited by liquid manure as their pots get filled with roots; but in all cases let it not be given too strong, and always in a transparent condition; if applied thick and muddy it closes up the surface of the soil, doing more harm than good. Even in May we frequently get cold cutting winds; therefore, when such is the case, never give air at both top and bottom of stoves, as it causes a through current of cold air, which is equally as injurious to vegetable as it is to animal life. We are frequently told that if the openings where the air is admitted are opposite the hot pipes, the air is warmed in its ingress by passing over the heated surface. To some extent it is, but not sufficiently; neither is it sufficiently charged with moisture to be allowed to rush onward on a windy day amongst young tender foliage at this season of the year; towards the autumn, when the object is to ripen up late growth, the case is different. Place Gloxinias, Tydeas, and all soft quick-growing plants near the glass, so as to get all the light possible; otherwise, when they have to be removed for decoration elsewhere, or their flowers are required for cutting, they are so soft and flimsy as to be useless.

Fern House.—Plants that have not been repotted for some time, and where it is not deemed advisable to give them more root room, may be assisted by the application of manure water; but in all cases see that the drainage is effective, otherwise its application will only aggravate the evil. If any plants are out-growing their bounds,

either in pots or planted out, it is an easy matter to reduce this over-luxuriance by cutting away, more or less, according to circumstances, their oldest fronds whilst in a green living state; this will be found to reduce the size of the young fronds made afterwards, in proportion to the extent it has been carried out. The different kinds of Dicksonia, Lomaria, Cyathea, &c., that throw up their young fronds in a batch may have, when these are fully developed, the oldest fronds, if unwisely, cut away.

Orchids.—This and the ensuing month is generally the gayest period of the year as far as these plants are concerned. The great drawback to the enjoyment of Orchids during this their flowering season, is that many of the plants occupying the different structures devoted to their culture are now in active growth, necessitating a high temperature and humid atmosphere. Where numbers of plants are grown, therefore, a small house should be devoted to such as are in flower; this can be kept drier, so as to prolong their flowers, and also cooler, than is required for such as are in active growth, at the same time affording facilities for inspection without the infliction of a vapour bath. See that Dendrobiums, especially such as are found in the almost saturated atmosphere of the hill regions of India, receive an abundance of water, both at their roots, and in the atmosphere during their season of growth. Keep them also in a lower temperature than is required for the well-being of such plants as inhabit the low hotter regions. The greater number of Cattleyas, including Mossia, labiate, Skinneri, and intermedia; Lealia purpurata and crispa, &c., are also very impatient of too much water at the roots, even during their season of growth, unless where the temperature in which they are grown is higher than either is necessary or desirable.

Hard-wooded Plants.—Azaleas will now be coming into flower without the assistance of fire heat, and although with the increased temperature of the season they will not last in bloom so long as those that have been forced, yet the much brighter colours which they acquire under more natural conditions will compensate for their shorter duration. The house they occupy whilst in bloom should be well shaded, in order to prolong their flowering as long as possible. Remove all seed pods from such as have done flowering; after which, allow them a fortnight or three weeks to recruit their energies previous to repotting. Use in the operation good fibrous peat broken into pieces proportionate to the size of the plants; add nothing except as much silver sand as will not only insure porosity, but also maintain a sweet healthy condition of the soil for years; for Azaleas with anything like fair treatment are not short lived. After potting keep them in a closer atmosphere than they have been in for a few weeks, and shade during bright sunny weather. Admit no side air during such time, but give sufficient at top to keep the temperature from getting too high; 80° or 85° with air, shade, and moisture will do no harm; on the contrary Azaleas enjoy it. Plants that are vigorous and that push some of their shoots very strong will be benefited by having the points of such shoots nipped out, as soon as they show a disposition to outrun their neighbours; if done whilst the growth is soft the plants will push several shoots, which will set blooms with the rest of the plant. Attend as heretofore to the general stock of hard-wooded plants, and by close attention encourage early and vigorous growth.

THE FLOWER GARDEN.

BY GEORGE WESTLAND, WITLEY COURT.

ALTHOUGH our springs of late years have cautioned gardeners as to the propriety of early "bedding out"—many preferring to wait until the first week in June before they commit tender plants to the open ground—it is not too early to decide how the garden shall be planted, and to make arrangements accordingly. What may be termed the massing system has had its day, and it is evident that something fresh must soon be introduced. Gardeners, it is to be regretted, have in too many instances prided themselves more upon the tens of thousands of plants bedded out, than upon the good taste which should have characterised their distribution. Striking masses of primary colour are all very well when viewed from a distance and when well balanced by an ample background of green; but close under the windows of the mansion, associated with light-coloured walks and bright statuary, they not only become offensive to the eye, but in sunny weather positively intolerable. London describes a beautiful scene "as one which an artist would like to paint," but we wonder where the artist could be found who would like to paint even the best of our modern flower gardens. As examples of broad masses of mere colour, and of the ability to crowd the greatest quantity of plants into the smallest space, they are well enough; but refined taste repudiates such ostentatious colouring. Nevertheless, bold masses of brilliant colours are not always out of place. Who at the present time, whether travelling by rail or road, can abstain from

admiring the soft, bright tint of the Larch? Some of the Acers, too, are scarcely less beautiful; while the grey of the Poplar and the brown of the Elm contrast admirably with the sombre green of some of the Pinus tribe; and the snowy blossoms of the Bird-cherry are everywhere enchanting; but, on the other hand, go again later in the season to our health-empurpled mountains and moorlands, and though the expanse may be lovely, who is not delighted when a break of Fern, a group of Foxgloves, or even a few scrubby bushes of Birch, Thorn, or the golden Furze step in to break the monotony? This is what we want in our gardens. The flavour of the Quince in the Apple-tart is good, but an Apple-tart nearly all Quinces would not be catable; just the same is it with our modern flower gardens; where we have striven for effect we must henceforth be satisfied with quiet repose. Towards this point are we drifting when we introduce foliage and sub-tropical plants into our flower gardens; and it is, to the artistic disposition of these—the judicious blending, as it were, of colour with form—we must look for a satisfactory solution of our present flower-garden difficulty. We would have masses of colour in suitable situations, but we would have them subdued and tastefully toned down by means of foliage, so as to form a rich, quiet, and harmonious whole. Even ribbons, if a mere repetition of the same plants *ad infinitum*, cease to charm; and the same holds good in the case of paneling and carpet-bedding, where gaudy colours are employed.

We would, therefore, as the planting season is at hand, council our readers to put in practice the subdued system of decoration; and, where it may be necessary to introduce colour boldly, so to tone it down by foliage and contrast as to produce a harmonious and pleasing picture. The secret of garden decoration does not consist in crowding hundreds or thousands of plants, however scarce or valuable, into a given space. No; it lies more in the judicious use of appropriate plants, and in so lighting them up by means of colour that each shall enhance the beauty of the other. For this purpose expensive materials are unnecessary; it is the arrangement rather than the plants individually which charms. One man, with a handful of flowers from the hedgerow will often produce an exquisite bouquet; while another, with flowers however choice, might fail. Tasteful application of the material which may be at command is what is wanted.

Spring-flowering plants, although now doing good service, will soon require to be removed to the reserve garden, the ground in which should be put in order to receive them; add to it a little thoroughly decomposed manure, leaf soil, or peat as the case may be. Before re-planting, divide into small portions such plants as Aubrietas, Arabis, and Daisies, &c., allowing sufficient space between the plants for proper development, without crowding. Bulbs must be removed in as perfect a manner as possible, being careful not to bruise the leaves in the operation, and on no account remove the flower stems, as they greatly assist the maturation of the roots. Water freely, and protect from sunshine for a few days with evergreen branches. Plant out spring-struck Hollyhocks, and divide and re-plant Neapolitan and late-flowering Violets. Centaureas should be plunged in the beds in pots, as they grow more compactly, colour better, and are more manageable in winter. Clip box edgings, and everywhere maintain perfect neatness and order.

Pits and Frames.—The majority of bedding plants now occupying these may be placed under temporary protection, preparatory to being planted out. Attend to the pricking off of tender annuals, and push forward what potting off may yet remain to be done. Abundance of space and air should be afforded to the more tender bedding plants, so as to insure sturdy, well-matured growth. Continue to make sowings of tender annuals.

THE ROSE GARDEN.

BY GEORGE PAUL.

In the case of Roses on the briar, suckers seem peculiarly troublesome this year, and their removal demands immediate and continued attention. Look for them carefully in the head of the trees, and check any incipient shoots that appear on the stem. On the budded briars of last year they will be found in abundance, and entirely overpowering the variety budded; in this case all should be removed at once, except one just above the breaking bud. This may be left for a day or two in full vigour, then shortened, and finally, in about a week altogether, be cut off. Experience shows that too sudden a check, before the bud has time to carry off all the sap, kills the now abundantly-forming white rootlets.

In early districts and on hill-tops, where frost threatens not, a dressing of guano or dried blood (ammonia with carbon) will be beneficial to the growth. In the valleys we are afraid to encourage a vigorous sappy growth, too often finding ourselves overtaken by May frosts, and prefer awaiting the benefits arising from a mulching of

droppings, to be prepared for application just as the buds are swelling and the hot season is setting in. Take advantage of the softer condition of the ground after showers to break up any clods still left after digging; hoe deeply and frequently.

Careful and almost daily search should be made for maggots; they lie often close to the flower bud, gnawing through the stalk just below it; when not looked after, the foliage, eaten and ragged, is a disfigurement for the whole season.

Towards the end of the month, plant out dwarf Teas, and more especially Roses on their own roots in pots; the latter get so much better established than if left until autumn, or when put out in winter.

Last week and the present first week in May is emphatically the season for pot roses; they are never so fine as when in flower now, and with the not too hot weather which we are now experiencing, they last long in bloom. They open, with the cool treatment now possible, large in size and fine in colour. The house in which the plants are opening their blooms should be kept shaded from all mid-day sun; a temperature of 55°, the happy medium, is not always possible at mid-day, but by plenty of water on the floor and amongst the pots a comparatively cool and moist atmosphere may be produced. If wanted for a particular date, hastening on the bloom may be done by a warmer and closer night temperature; but if they may be allowed to come in regardless of shows or garden parties, air may be left on and a cool night temperature may be maintained with obvious advantage to the size of the blooms. Pot roses for June cannot have too much air or be grown too slowly. In tying, plants should be gone through a second and last time when the growth is fully made and the operator can see how far out his flowers will be.

THE FRUIT GARDEN.

BY WILLIAM TILLERY, WELBECK.

Outdoor Fruits.—Our fickle climate has never been better represented than it has been lately, for on April 21st it snowed here nearly all day, with a frosty north-east gale prevailing all the time. The latest flowering portion of standard Pears, Plums, and Cherries, being then in full bloom, the prospects of a good crop of these fruits are again somewhat blighted. Last year the rainy, cold weather which we had in April and May prevented some kinds of outdoor fruits from setting well, especially Apples, and very thin crops were the result in nearly every locality. Where Apricots, Peaches, and Nectarines have been protected, the coverings will want gradually taking off, so that the trees may not suffer from too sudden exposure. Disbudding the shoots, by only taking off a few at a time, till all danger from the influence of cold weather is over, must now be proceeded with; and where this is properly done it adds to the beauty and health of the trees. Where the fruit has set thickly, timely attention to thinning must be observed; but I am afraid this operation will be a sinecure this year on many kinds of fruit trees. Apricot trees are often much infested with the grub, that curls their leaves up and eats the young fruit. As this pest is safe from syringings or dressings of any kind, it must be searched for and crushed with the finger and thumb; and the more effectually this is done, the fewer grubs will appear next year. Peach and Nectarine trees on the walls, if infested with green fly, must be syringed with tobacco water; and this, if done in time, will prevent them from injuring the foliage. Attend to the stopping of all fore-right shoots on Pears, Plums, and Cherries on the walls. Towards the end of the month, Strawberries will be beginning to swell their fruit; and for all the large, valuable dessert kinds, forked sticks should be placed in the rows to support the trusses. This I find is far better than laying straw, short grass, or hay down to keep the fruit clean, as these materials harbour snails and other vermin.

Orchard House Fruit Trees.—In true orchard houses, that is, where no artificial heat is employed, the temperature must be ruled by the weather. It is advisable, therefore, on bright sunny days to close the lights early in the afternoon, to secure a higher temperature for the night. Disbudding and pinching all strong shoots, and thinning the fruit where set too thickly, will be the routine for this month. Green fly and red spider must be eradicated by fumigation or syringing with tobacco water.

Vineries.—The Vines in the early houses will now be ripening, and some air left on at night will assist the colouring process. In the succession houses, where the Vines are in flower, good fires must be kept up, and plenty of air given when the weather permits. Thinning the berries as soon as they are fit, stopping the laterals at a leaf or two above the bunches, and removing all superfluous shoots will be the main points now to attend to in the latest vineries. The coverings may now be removed from all the outside

borders, and some liquid manure applied to them when watering is necessary.

Peach Houses.—The fruit in the earliest peach house will now be at its second swelling, and the border must be examined to see that the moisture is sufficient, especially where the roots are all inside the house. Abundance of air must be given when the fruit is colouring, and the watering at the roots gradually discontinued. The trees in the late succession houses must be syringed every afternoon, and a moist atmosphere kept to prevent red spider from injuring the foliage. Soft water, at a temperature as high as that of the house, should be used for this purpose, for hard water stains the foliage and fruit with carbonate of lime, and spoils the bloom on the fruit when ripe. The thinning of the fruit must be attended to, and the quantity left on be regulated by the health of the trees. I find the best soil for Peach and Nectarine borders, where such can be procured, is the turfly loam from old pastures or the sides of roads, and no manure or compost of any kind added to it. Peach trees grown in such soils never make too gross or unhealthy wood, and they can always be kept up to the desired vigour by an addition of fresh soil to the roots, and liquid manure during the time the fruit is swelling. All leaf mould, old tan, or any compost or soil that is likely to bring funguses into Peach-tree borders, should be strictly avoided when making them, for when fungus fastens on the roots of Peach trees it soon renders them unhealthy and unproductive.

Figs.—As the first crop of fruit will be about ripening, the supply of water to the roots must be diminished, and only sufficient given to prevent the second crop from dropping off. The trees grown on walls after the winter coverings are removed will want their wood thinned, and all the shoots left nailed or tied in.

Cherry House.—As soon as the fruit is all gathered, the trees must get all the air possible by taking the lights off or opening them to their fullest extent. When grown in tubs or pots, the trees can be placed in the open air in some sheltered situation, and not neglected for water in dry weather. Syringe with tobacco water, or fumigate, should the black aphis make its appearance on the trees.

Cucumbers and Melons.—A steady bottom heat will still want keeping up, and by attention to syringing and a moist atmosphere the foliage will appear clean and healthy. The fruits on both Melon and Cucumber plants often set too many at a time, and require thinning, so as not to weaken the plants too much. Put pieces of slate or glass under Melons grown in frames, to prevent the damp soil from rotting the young fruit. When Melons are grown in pits and the plants trained on wires or trellises the fruit when getting heavy must be supported on a square piece of wood with a piece of string fastened to each corner tied to the wires, leaving plenty of room for the fruit to swell to their full size. Plants in frames will still want covering up with mats at night, and continued till all danger from cold weather is over. The ridge Cucumbers sown in May will want planting out by the end of the month, and a suitable ridge or bed made with hot dung will want preparing for their reception. Vegetable Marrows will likewise want planting out at the same time, and in the same way.

Strawberries.—When the fruit is all gathered from forced Strawberries the plants are often huddled together in some exposed corner and neglected; but such plants, if taken care of and planted out, will furnish fine fruiting plants next year in the open air. Some varieties likewise when planted out early produce a good crop in the autumn, and notably Sir Charles Napier for one, as I had this variety very fine last year in September, and quite fit for dessert. If the ground cannot be got ready for planting them out till other crops come off, and the pots are wanted, the plants may be shaken out and packed closely together with a little mould sprinkled amongst them, when they will be safe till planting-time, if supplied with water in dry weather. Take advantage of favourable weather to clean between the plants, and to mulch them properly in good time. Where the soil is light and open, tread it firmly previous to mulching.

THE PINERY.

BY JAMES BARNES.

To make fruit swell off freely, now that the days are long and light, ought to be no difficulty. All that is required is method in the way of applying necessaries, such as tepid manure water, charging the atmosphere with ammonia and humidity, kindly airings occasionally, and never shading if well swelled, finely-coloured fruit is aimed at. Talk of shading, indeed, in our cloudy, dark, humid climate, where the general complaint always is what little sun we get! Oh, no; to deprive our fruits of that little is against all natural reason and law. Succession plants in every stage of growth

should now get their full share of heat, humidity, and air, with a warm humid atmosphere. Air freely night and day, in order to get strong robust plants.

THE KITCHEN GARDEN.

BY JAMES BARNES.

In order that vegetation may make proper progress, stir the surface of the soil frequently and well amongst growing crops, by means of the hand scarifier, Dutch and draw hoes. Unctious, stiff, wet soils must be methodically trenched, exposing as much of them as possible to the influence of sun and air, in a rough, ridged state. Forking, scarifying, hoeing, &c., at all seasons amongst crops is the masterpiece of good cultivation, giving neither vermin nor weeds a chance of existence. Make up vacancies by transplanting, or you tolerate a loss; everything can be transplanted by means of a trowel in each hand, one to open the hole and the other to take up the plant with a ball of earth attached to it. After-thinnings, when the plants are established, are made with crane-necked hoes, one in each hand, sharply looked after. Broccoli, make the last sowing of some late kind for the season; prick off all previously sown plants as soon as they can be handled; also those of Savoys, Brussels Sprouts, Borecole, and other Kales. Cauliflowers, plant these out in succession now, on the coldest, dampest situations you can select, and make small sowings for succession. Carrots, thin early sorts, and sow other early kinds in small quantities, in order to have always a succession of young roots. Beans, plant garden Beans on stiff, cold ground, and pinch the tops out of such as are coming into bloom. French Beans, transplanted or up and growing, dredge with dry dust, to prevent shanking or canker; shelter, where not under hand-glasses, with boards or boughs. Of Scarlet Runners, and other runner Beans, plant a full crop, sheltering and dredging them as just recommended for French Beans.

Celery.—To early plants in frames give air freely, and water abundantly; earth carefully, remove the lights entirely now, and make use of them for sheltering and assisting the second crop for a short time, or for French Beans, Capsicums, Chilies, Sweet Basil, &c. Young Celery for succession, continue to pick out; never allow the plants to get large or drawn previously with large tap roots, if fine, crisp, well-finished Celery is aimed at. The best situation for Celery at this season is in partial shade, that is, where tall late peas have been sown in rows, twelve or fourteen feet apart, as they always should be, in order to obtain a heavy, perfect crop, and where early crops of Spinach, Turnips, Cauliflowers, &c., have first been taken; between the Peas cast out a shallow trench, six feet wide, fork into it a good portion of good rotten manure, and plant seven or eight plants crossways in the trench, eighteen inches apart. Thus treated, the result cannot fail to be a heavy crop of fine Celery, and that with less trouble, labour, and expense, than by any other method, and in this way all the winter crops can be conveniently sheltered and protected from severe frost.

Lettuces.—Sow these once a fortnight in drills, on well-prepared ground, to be thinned by hand or hoe; they will grow away much freer without "bolting" from seed, than when transplanted in hot, dry weather.

Peas.—Of these continue to sow late varieties at good distances apart, in order to obtain good and perfect crops, and partial shade for intermediate cropping. Draw a ridge of earth up to within nine or ten inches of each side of all Peas up and ready for sticks, and place mulchings of decayed manure of some kind between the Peas, and the ridge on each side. It is astonishing how this benefits them by preventing evaporation, and it affords convenience for applications of water. Stop or pinch out the tops of all early blooming Peas; and all late kinds and strong growers should be first stopped when two feet in height, and three or four times afterwards, in order to get heavy crops.

Seakale.—Manure and fork the ground between crops of this that have been cut; thin the crowns early to two or three shoots, according to strength, and apply dredgings of soty pretty freely in rainy, dark, cloudy weather. Seakale grows naturally in great abundance, as do also Cabbages and Asparagus, round this coast close to the sea.

Tomatoes.—These should now be planted out against walls, close fences, under hand-glasses at the bottom of steep sloping banks, or in warm valleys against stakes, &c.; they may be trained and led with one shoot up to any bare spots on walls between fruit trees, then stopped to fill up. The Tomato is a wholesome fruit not grown or made use of in this country to the extent it should be.

Radishes, Mustard and Cress, Chervil, and other saladings, sow little and often; and make a small sowing of Endive.

Turnips, sow these in small portions, in drills on the coldest and dampest land that can be found.

THE HOUSEHOLD.

GREEN PEA SOUP IN WINTER AND SPRING.

Sow Peas thickly in pots and boxes, say six weeks before the soup is wanted. Place them in a temperature of 60° or so, close to the glass in a house or pit. Cut the plants as soon as they attain a height of from three to six inches, and rub them through a sieve. The shoots alone will make a fair soup. Mixed with dry peas, also passed through a sieve, no one could scarcely distinguish colour or flavour from that of real green pea soup. There is, however, considerable difference in the flavour of pea leaves, as well as of the peas themselves. The best marrows, such as No. Plus Ultra and Veitch's Perfection, yield the most piquant cuttings. Also the more light the plants receive the higher the flavour; plants drawn up, or at all blanched, being by no means comparable with those well and strongly grown.

In the spring, a few patches or rows may be sown in open quarters expressly for green cuttings. These are most perfect and full flavoured when four inches high. When too long, the flavour seems to have run to wood, and the peculiar aroma of green peas is weaker.

There is yet another mode of making green pea soup at any season at very short notice. Chip the peas by steeping them in water and leaving them in a warm place for a few days. Then slightly boil or stew, chips and all, and pass them through a sieve. The flavour is full and good, though such pea soup lacks colour. It is astonishing how much the mere vegetation of seeds develops their more active and predominant flavour or qualities; a fact that might often be turned to useful account in the kitchen in the flavouring of soups or dishes, with turnips, celery, parsley, &c.

D. T. FISH.

FLAVOURING WITH LEAVES.

LEAVES are more or less popular for garnishing, but it has often surprised me that they are so little used for flavouring. With the exception of sweet and bitter herbs grown chiefly for the purpose and parsley, which is neither bitter nor sweet, but the most popular of all flavouring plants, comparatively few other leaves are used. Perhaps I ought also to except the sweet bay, which is popular in rice and other puddings, and certainly imparts one of the most pleasant and exquisite flavours. But, on the other hand, what a waste there is of the flavouring properties of peach, almond, and laurel leaves, so richly charged with the essence of bitter almonds, so much used in most kitchens! Of course, such leaves must be used with caution, but so must the spirit as well. An infusion of these could readily be made, either green or dry, and a tea or table spoonful of the flavouring liquor used to taste.

One of the most useful and harmless of all leaves for flavouring is that of the common syringa. When cucumbers are scarce, these are a perfect substitute in salads or anything in which that flavour is desired. The taste is not only like that of cucumbers, but identical—a curious instance of the correlation of flavours in widely different families.

Again, the young leaves of cucumbers have a striking likeness in the way of flavour to that of the fruit. The same may be affirmed of carrot tops, which are as like carrots in taste as may be. In most gardens there is a prodigious waste of celery flavour in the sacrifice of the external leaves and their partially blanched footstalks. Scores of sticks of celery are cut up into soup, when the outsides would flavour it equally well or better.

The young leaves of gooseberries added to bottled fruit give a fresher flavour and a greener colour to pies and tarts. The leaves of the flowering currant give a sort of intermediate flavour between that of black currants and red. Orange, citron, and lemon leaves impart a flavouring equal to that of the fruit and rind combined, and somewhat different from both. A few leaves added to pies or boiled in the milk used to bake with rice, or formed into crusts or paste, impart an admirable and almost imitable bouquet. In short, leaves are not half so much used for seasoning purposes as they might be.

D. BURY.

Flavouring with Seeds.—For the dead season, when greens are scarce, or frost has made a full and final meal of them, it may be of service to bear in mind that we can turn to seeds, dry or chipped, for various flavours. I have already adverted to such as celery, turnips, and parsley, among vegetables. The seeds of most herbs possess similar characteristics; such seeds as those of thyme, marjoram, or savory, taste very like the plants. But most herbs may be dried and bottled, and it is comparatively easy to have such, either green or dry, in sufficient quantity; it is, however, often otherwise with parsley. Its seed is of fair size and substance, and the flavour much concentrated, so that a little goes a

long way. For soups, &c., the seed boiled is a capital substitute for the leaves. For melted butter the great drawback is colour. But even this may be overcome by the employment of a neutral green to mix with strong parsley seed water. Perhaps this neutral tint is given by mild Scotch kale, grated as parsley is for melted butter. The colour is almost identical, and the flavour can be parsleyed over so completely as to defy distinction.

—D. T. FISH.

THE FRUIT GARDEN.

PEARS IN THE CHANNEL ISLANDS.

In reply to Mr. Baines (p. 415), as to why I named only two sorts of Pears in my former paper, I beg to say that I did so because the two kinds mentioned are well-known to most persons. I am glad to see Mr. Baines's acknowledgment that the Chaumontel and Duchesse d'Angoulême are of better quality grown in the Channel Islands than those of English growth; and I can safely affirm that the same is the case with all other first-class Pears with which I am acquainted, or have ever seen grown. The Channel Islands are the land of Pears, all of which can be grown to first-rate perfection, both as to quality and size. And why should it not be so? England, as a whole, is not the best of Pear-growing countries. Apples do better in it than Pears. I am aware that many good Pears are grown in England, but the sorts must be selected with care for the different localities; and even then, often after much trouble and expense, they do not equal those grown either here or in France. In most parts of England many sorts have to be given up in despair; and, as Mr. Baines says, the further north the worse they are. He might also have added too far south is just the same. There, also, Pears will be found "no better than turnips." Mr. Baines appears to have overlooked the fact that there is a happy medium in most things, and in nothing is it more conspicuous than in growing first-class Pears. All good cultivators of the Pear are agreed that too great heat, too great an amount of cold, or any changeable temperature, is fatal to those who aim at growing first-class quality fruit, either for size or flavour. Such being the case, I affirm that few, if any, places will beat the Channel Islands for the flavour of their fruit. Never mind what sorts are cultivated, they will all be first-class in that respect. First: We have an excellent soil, in which the Pear delights to grow. Second: Our temperature neither rises too high nor falls too low in summer, which is frequently the reverse in England, our insular position obviating extremes. Third: We have longer summers, which commence earlier in spring and last longer in autumn; a point of primary importance to late-keeping and long-hanging fruit. Thus it is evident that we have great advantages on our side as regards growing first-class Pears, either for size or quality. I myself cultivate upwards of two hundred varieties of Pears, some of which are the most delicate and tender in cultivation. My trees are wholly grown as pyramids or as ground cordons, and they receive no protection of any kind. They invariably produce good crops, and ripen fruit to the highest perfection. Among them are to be found sorts that I feel confident Mr. Baines would not equal even with the aid of walls; and I am led to this conclusion from observing that Mr. Baines calls the Chaumontel a coarse fruit. I have an idea that Mr. Baines is too far north, or he could never call the Chaumontel a coarse Pear, for few if any Pears can beat it for flavour; and if all its good qualities are taken into consideration, it cannot be surpassed by any Pear in cultivation—of course, I mean when grown in a favourable climate, such as we have here. Those Pears named by Mr. Baines are good sorts, and will bear good fruit in most parts of England where Pears do anything at all, excepting Marie Louise, which is rather tender in some places; and this Pear, also, is better flavoured here than even in Devonshire, where I have seen it in beautiful condition against a south wall. I believe I may repeat with certainty that no better Pears can be grown in Europe for size or flavour than are grown in the Channel Islands and France, say as far as the river Loire. South of this the flavour decreases, and far south Pears get worse and worse, until they become little "better than turnips;" and there we enter the land of grapes, figs, olives, melons, &c. JOHN RICHARD WILLIS, *Rohais Nursery, Guernsey.*

ORCHARD HOUSES.

WE have here a very good span-roofed orchard house, measuring seventy-five feet long, twenty-two feet wide, and fifteen feet high. From the time we gather from this house our first dish of currants, raspberries, and gooseberries, for tarts, up to the month of October, when we gather the last dish of Easter Beurrey pears, the house is full of interest. It will be seen that we do not gather superior fruits at the beginning of the season, but we gather peaches and apricots, nectarines, plums, and cherries by the hundred afterwards,

and apples and pears by the dozen. The greatest drawback is not having plenty of fruit trees to go on with when the house is built. On the trees in pots first bought, I have no doubt there will be a good crop the first season, if the selection has been rightly made; but next year, putting all together, a good crop will seldom be obtained. What, therefore, is to be done? Instead of buying only one set of trees at first, buy two; one set to be in pots to begin with, the second unpotted and from two to four feet high, which should be planted rather closely in a sheltered but sunny situation, and if practicable in a stiff, yellow loam, in which they should be planted pretty firmly and allowed to remain undisturbed till the following season. The following February examine your trees in the orchard house, and those that bore a heavy crop the previous season, if not likely to be very productive this year, as they will not probably bear, remove them to the outside; and in their place take in those planted out. Lift these with good balls, and pot them firmly in good, stiff loam, mixed with a little bone dust. By yearly pursuing this practice, no lack of fruit need be experienced. In this house last year we had a small plant of Williams's Bon Chrétien pear, that produced six fine fruits, averaging in weight sixteen ounces each, and of superior flavour. I quite agree with your correspondent "W." in saying that those who have never tasted a well-ripened pear, produced under glass, have something in store. So fine is the flavour of these pears that they are always eaten even in preference to peaches or grapes. The currants, gooseberries, and raspberries which we bring forward under glass for tarts, are all removed before they in any way prove injurious to the regular inmates of the house.

T. SOUTHWORTH.

Castle Head, Morecambe Bay.

Fruit Improvement in Canada.—As evidence of this it is only necessary to call to mind the magnificent displays of fruit that have now for several years formed so conspicuous and attractive a feature in our provincial exhibitions, and which have elicited the admiration of all beholders. The change is also shown by the fact, that whereas we used to be dependent upon our neighbours across the line for our supply of nearly all kinds of fruit, we now not only raise sufficient of the harder sorts to meet the demands of home consumption, but we annually ship large quantities of apples for the English market. The culture of the grape has also been prosecuted with most encouraging success, and is spreading rapidly. Still further proof of our progress in the same direction is furnished by the growth of the nursery business in this country. There is not a nurseryman in the Dominion, though their number and the extent of their transactions have greatly increased, who is not taxed to the very utmost to supply the demand for ornamental, shade, and fruit trees; and the results are visible in the neat aspect of city garden plots, the charming grounds of suburban residences, and the improved appearance of farm homesteads.—*Canada Farmer.*

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

(MAY 1st.)

Nor a large meeting, but one worthy of the brilliant May-day on which it was held, in the variety and beauty of the subjects shown.

Roses were abundant and remarkably fine, especially three boxes of cut blooms of Marechal Niel, which were excellent. The bright golden flowers of this Rose, its free-flowering qualities, and its suitability for greenhouse decoration as a climber, deservedly render it a universal favourite. Amongst other plants the most remarkable were two superb examples of Saracenia from Mr. Baines, of Southgate, surpassing in size and in perfectness of development even the noble specimens of these plants so often shown by Mr. Baines, both in London and Manchester. To these a silver floral medal was awarded. We noticed some improvement in the mode of showing herbaceous and alpine plants, Mr. Ware sending flat baskets crammed with the alpine Phloxes of America. Thus shown, the beauty of alpine flowers is well brought out, and the fact plainly showing that they surpass all other plants in profusion of blossom. Eucharis amazonica was shown by Mr. Standish, a fine specimen with nineteen flower spikes on it, each spike bearing some six flowers; the plant itself, which was growing in a small tub, measured five feet in diameter. Of bedding Pelargoniums some were shown in fine condition; tricolors we noticed with finely marked foliage; also white variegated-leaved kinds bearing pure white flowers, and judging from their compact habit, and apparent free-flowering qualities, we have in them obtained something good for summer outdoor work. Orchids were exhibited in great variety and beauty; conspicuous amongst them was Mesopspodium sanguineum, with three gracefully drooping spikes of charming bright rosy flowers. Cut flowers of Ranunculus from Mr. Hooper, of Bath, were contributed in excellent condition; as were likewise cut blooms of Pansies in great variety, fine in form, and distinct in colour.

Amongst new plants, a first-class certificate was awarded to Echinocactus Mirabilis, a curious and deeply-furrowed species, with clusters of large spines, from Mr. Peacock's admirable collection at Sudbury House, Hammersmith. Few private collections of these curious plants are so rich in interest as this; their requirements are well understood by Mr. Croucher, who grows them in perfection, and many species nowhere else

to be met with in Britain may be seen here. First-class certificates were also awarded to Encephalartos cycadifolia, from Mr. B. S. Williams, Upper Holloway; to a dark copper-coloured long-leaved Dracena, much after the form of *D. indivisa*, from Messrs. Rollinson & Son, Tooting; to Odontoglossum brevifolium, a distinct kind, with dark flowers and thick leathery leaves, but of a very unruly habit, from Mr. J. Linden, Belgium; to Bouvardia longiflora flammula, a promising rose-coloured kind, from Messrs. E. G. Henderson & Son, St. John's Wood; to Pansies, Mrs. Eyles, Prince of Wales, and Crimson Beauty, from Mr. Hooper; to Auriculas Mercury and Colonel Scott, two good new kinds, and to Azalea Fanny Ivory, a brilliant red kind, from Messrs. J. Ivory & Sons, Dorking; and to an alpine Pentstemon, from Messrs. Veitch, Chelsea. This, a very distinct and pretty little magenta-coloured Pentstemon, found by Mr. W. Robinson on the summit of the Rocky Mountains, was one of the most admired. It was not shown in its best state, as naturally it is a tiny, neat-habited shrub, two to three and a half inches high, forming round tufts associated with the alpine Phloxes.

Mr. Francis Dancer sent from his excellently-managed market garden at Chiswick, a noble dish of Asparagus. His system is the opposite of that of those who crowd thickly a number of plants into a bed. He leaves three feet or so between each plant. Mr. Dancer, good judge as he is, and ought from his practice to be, does not agree with those who wildly write in the papers, shoving how very foolish people are who eat blanched Asparagus. These, for the most part, found their opinion of the blanched Asparagus on imported specimens, that have been perhaps blanched to within two or two and a half inches of the top; properly done Asparagus is most delicious treated thus, at least so it seems to those who have given both ways a fair trial.

A fine example of Blue Gown Cucumber, about two feet in length, was exhibited by Mr. J. Reven, gardener to E. Forrest, Esq., Orpington, Kent; this arrived too late to come under the notice of the judges. A Melon, called Little Heath, weighing four pounds ten ounces, was shown by Mr. Monro, Potter's Bar, Barnet.

Fruit, although not shown in quantity, was as far as it went, excellent. New Grapes in good condition consisted of Black Hamburg and Buckland Sweetwater. A dish of Gross Mignonne Peaches, and one of Violette and Brown Turkey Figs were also contributed in good condition, as were likewise dishes of Dr. Hogg and Marguerite Strawberries, both fine-looking fruit.

EXHIBITION OF USEFUL AND HURTFUL INSECTS.

In order to diffuse a knowledge of the natural history of insects affecting field and garden crops, and to enable agriculturists, gardeners, fruit-growers, and others interested in the matter, not only to familiarise themselves with the appearance and transformations of their insect friends and foes, but also to become acquainted with the most effective means of encouraging the former and checking the ravages of the latter, the Central Agricultural Society of France is making arrangements for an entomological exhibition, to be held in the Luxembourg Garden, in Paris, between the 18th August and 3rd September next.

The exhibition will be divided into four sections, the first of which is to contain all the useful insects, ranged under six classes, and represented in their different stages of development, from the egg to the perfect being. Each class must be accompanied by a specimen of the food on which the insect lives, as well as by a short account of the usual method of rearing it, of its natural history, economy, products, average market value, &c.

The second section will consist of noxious insects, and as basis of classification the authorities have taken the plants which they consider it most important to protect, placing together in groups all those insects which attack the same crop or produce. This classification is perhaps not scientific, but it possesses at all events the advantage—it is hoped—of being easily comprehended, and of facilitating study. All the chief crops and objects of culture to be met with in France, including fruit and forest trees, will be represented in this section, together with the minute population to which they afford nourishment. Thus, for instance, class seven will contain insects living upon timber; class eight those infesting truffles and mushrooms; class nine such as destroy dry organic substances (woollen goods, feathers, horsehair, &c.); and class ten, parasites of the domestic animals and man.

On the one hand, place will be found for carnivorous insects, down to the parasites of the plant-louse and of different moths and butterflies; on the other, the claims to representation of insectivorous mammalia, such as the mole, hedgehog, &c., as also of insectivorous birds, will not be forgotten.

The exhibition is also to embrace two entirely non-entomological sections, one of them devoted to river fish culture, the other illustrative of the rearing of edible snails, and of the damage done by snails and slugs. An enumeration of the simplest and most efficacious means of destroying these pests will be added, for the benefit of horticulturists and vine-growers—the greatest sufferers by their depredations.

Although the different collections will be so systematically arranged and catalogued as to tell their own tale, it is thought the instructive lessons they convey will be more deeply impressed on the minds of visitors if "conferences" be held in connection with the exhibition, the subjects of discussion at the same to be decided upon beforehand. This plan was followed with the best results at the last entomological exhibition in the Palais de l'Industrie (Champs Elysées), the conferences being well attended and exciting much interest. Communications relative to the exhibition should be addressed before the 1st of August to the secretary of the society, 59, Rue Monge, Paris.—*Field.*

ONE of our enthusiastic correspondents, prompted, no doubt, by the genial warmth of the season, has broken into flower with the following:—

SWEET MAY.

SWEET greeting to thee, May!—may we,
Sweet child of Sun,—run
To thy daisied lap,—and lap
From dew-sprent lids “day’s eye!”
And if not, why not?—knot thee
In our heart of hearts—for art
Thou not, with all thy love and light—light—
Hearted May! our May? and may we
For ever call thee ours—and hours—
Sweet hours of young life’s prime—chime
Sweetly in our hearts—where rime don’t fall,
Nor frost at all—only light, flowers, and sun—won,—
By the smile, may come—trippingly as thou dear daisied May;
And oft, in joyance, may we greet this day—

Mayn’t we? SWEET MAY!

May Day, 1872.

COVENT GARDEN MARKET.—May 3rd.

Flowers.—Those in pots consist chiefly of Pelargoniums of all classes, well flowered and abundant; herbaceous Calceolarias, charmingly marked and well-grown; Gardenias, indispensable on account of their sweetness; Golden-rayed Lilies, graceful little Fuchsias; spring flowering Heaths in great variety; Roses of most kinds, more especially the pretty dwarf Chinese sorts; and many other plants of interest. To these may be added fine-leaved plants such as Dracunculus, Ferns (principally Adiantums), graceful kinds of Pteris and Podocarpus; Palms, Cyperuses, and Club Mosses. Bouquet flowers mostly consist of light-coloured Tea Roses, Stephanotis, White Azaleas, Blue Cinerarias, Double-flowering Stock, sprays of various Orchids, Gardenias, Lily of the Valley, Ferns, &c. Buttercups include a Gardenia flower with a few leaves; light Rose with leaf; red Pink; spray of Lily of the Valley and Fern; Stephanotis and Fern; Hoyia, cluster of flowers; and Fern; Nemophila; and a few other flowers were also worked into them. Hardy plants are now furnished in great plenty; amongst them are Pansies, Sweet Williams, Stocks, Alyssum, blue Gentians, double-flowering Ranunculus, Minimuluses, Carnations, &c.; also Nasturtiums and Sweet Peas, and other plants of similar kinds.

ANSWERS TO CORRESPONDENTS.*

BINFIELD (Through any of the large London nurserymen.)—RALPH (In its present stage your plant is indescribable. In New Zealand Sophora tetrapeta grandiflora is called “Kowhai,” as is also the Edwardsia grandiflora of Salisbury.)—T.A.P. (There is no better way than that of allowing swans to graze down your watery meadows.)—W.B. (Many thanks. The contribution so kindly promised will be welcome.)—P. (The old double Primroses are, or were, not uncommon in Irish gardens.)—J.L.S. (Rhodanthes thrive well if sown in the open ground the last week in April.)—H. RAYLE (There is at least one of the American Hawthorns earlier than our common British one.)—Y. (We shall do our best to assist you.)—R. M. (Next week.)—H. C. (We are unacquainted with any separate work on the subject.)—C. H. (The cutting in of the Ivy on Hornsey Church Steeple will do no harm; on the contrary the bare stems will doubtless soon be again covered with new and beautiful foliage.)—

* All questions likely to interest our readers generally are answered in the several various departments.

J. O. (Mr. Baines recommends serim, a kind of flax fabric, see p. 531.) J. C. and P. J. N. (Next week.)—Miss K. (Leptospermum bullatum.)—O. M. (Camellias and Azaleas will, at the proper season, bear cutting in, not only without injury but sometimes with advantage. Perhaps your gardener objects to indiscriminate mutilation by those who cut flowers.)

ROYAL HORTICULTURAL SOCIETY.

(MAX 1ST.)

LIST OF PRIZES AND CERTIFICATES.

NINE Roses in pots—First, Mr. C. Turner, Slough; Second, Messrs. Paul & Sons, Cheshunt. 6 Roses in pots—First, Messrs. Veitch, Chelsea. 3 Roses in pots—First, Mr. E. Ellis, gardener to J. Galわworth, Esq., Kingston; Second, Mr. Baxter, gardener to C. Keiser, Esq., Brixton; Third, Mr. J. James, Islington.

12 Auriculas—First, Mr. C. Turner; Second, Mr. J. James. 6 Auriculas—First, Rev. H. Dombain; Second, Mr. J. James. 12 Alpine Auriculas—First, Mr. C. Turner; Second, Mr. J. James.

6 Azaleas—First, Messrs. H. Lane & Sons; Second, Mr. T. Hill, The Poplars, Regent’s Park; Third, Mr. C. Turner. 6 Azaleas—First, withheld; Second, Mr. J. Langford, Clapham Park; Third, Mr. C. Baldwin; Third, Mr. G. Wheeler; 3 Azaleas by Mr. J. James who have not previously taken the Society’s prize for 1871.

12 Exotic Orchids—First, Mr. Denning, Tadcaster; Second, Mr. William Ball; Third, Mr. G. Wheeler.

6 Herbaceous Calceolarias—First, Mr. J. James; Second, Mr. J. Dobson.

Culture commendations were awarded to Sarracenia flava and S. Drumondii and to from Bartsia, Bartsiae, Southgate; to a finely spotted Odontoglossum Alexander from Messrs. Veitch; to a specimen of the rarest form of Green Cherries, and one of Elton, from Mr. Stephens; gardener to the Duke ofutherland, Trentham Hall; to a dish of Black Cherries, and to a dish of Black Currant Cherries, and one of Elton, from Mr. Stephens; gardener to the Duke of Suffolk, Hartwell House, Aylesbury; to a dish of Violette and Brown Turkey Figs, from Mr. J. Tegg, gardener to J. Walter, Esq., Wokingham; to a dish of Marguerite Strawberries, from Mr. McKellar, Colworth; and to a dish of Dr. Hoggs, from Mr. J. Hopper, Hartwell House, Aylesbury; to three bunches of Black Hamburgh and three of Buckland Sweetwater Grapes, from Mr. J. Tegg; and also to three bunches of Black Hamburgh from Messrs. Wright, Lee, Kent.

His Serene Highness the Prince of Teck, president of the Royal Botanic Society, visited the gardens yesterday, and signed the nominations of the following vice-presidents for the present year:—The Duke of Buckingham and Chandos, K.G., the Marquis of Bristol, Lord Alfred Hervey, the Bishop of Winchester, D.D., F.R.S., Lord Calthorpe, Lord Chesham, Lord Tredegar, the Right Hon. Sir William Hutt, M.P., Sir Walter Stirling, Bart., and Sir Charles R. Turner.

EXHIBITIONS DURING MAY.—Royal Horticultural Society, South Kensington: Table decorations, Roses, Rhododendrons, Hardy Perennials in pots, hardy flowering Trees and Shrubs, Gloriosias, Carnations, Agaves, and Peas, 15th and 16th; Royal Botanic Society, Regent’s Park, 8th; last Spring Show, Reading Horticultural Society, 22nd; Crystal Palace, 11th; first great Flower Show, Manchester Botanical and Horticultural Society, 17th to 24th; Royal National Tulip Society, Grand National Horticultural Exhibition, Manchester, 25th; Sefton Park Great Horticultural Exhibition in aid of the new Southern Hospital, 21st to 23rd.

A LETTER FROM A MARKET GARDENER TO THE SECRETARY OF THE HORTICULTURAL SOCIETY.

Sir,—The Satiety having been pleased to Complement Me before I beg Leaf to Lie before Them again as follow in particularis with I hop They will luck upon with a Sowth Aspic.

This ear I have turnd my Eyes to Goberriis.—I am happy to Say I have allmost succidid in Making them too Big for Bottlin. I beg to Present sum of itch kind.—Pleas observe a Green Goose is larger in Siz then a Red Gooseby. Sir as to Cherries my atention has Been cheafly occupid by the Black Arts. Sum of them are as big as Cricket Balls as will be seen I send a Sample tyed on a Wauking-stick. I send likewise a Potle of strawberryis witch I hop will reach. They air so large as to object to lay more nor too in a Bed. Also a Potle of Hobbiis and one of my new Pins, of a remarkably sharp flavour. I hop they will cum to Hand in Time to be at your Feat. Respective Black red & White Currancy I have growed equally Large, so as one Bunch is not to be Put into a Galley Pot without jamming. My Pitches has not been Strong, and their is no Show on My Walls of the Plumb line. Damsins will be moor Plentifl & their is no Want of common Bullicies about Lunnon. Please inform if proper to classify the Slow with the creepers.

Concerning Graps I have bin recommded by mixing Wines with Warter Mellons, the later is improved in its juice—but have doubts of the fuck. Of the Patagonian Pickleing Cucumber, I have mad Trial of, and have hops of Growing one up to Markt by sitting one End agin my front dore. On account of its Proggersiveness I propos calling it Pickles Perrigrinatus if Approved of.

Sir, about Improving the common Stocks.—Of Haws I have some hops but am disporing about my Hyps. I have quite faled in culturating them into Cramberriis. I have also attempted to Mill Blackberis, but am satisfied them & the Mulberriis of difrent Genius. Pleas observe of Aples I have found a Grafft of the common Crab from its Straglin sideways of use to Hispaliess. I should like to be infourmed weather Scotch Granite is a variety of the Pom Granite &

weather as sum say so pore a frute, and nothing but Stone. Sir, My Engine Corn has been all eat up by the Burds namely Rocks and Ravines. In like manner I had a full Shew of Pees but was destroyd by the Spares. There as bean grate Mischef dun beside by Entymology—in some parts a compleat Patch of Blight. Their has bean a grata Deal too of Robin by boys and men picking and stealing but their has bean so many axidents by Steel Traps I don't like setting on 'em.—*Hood's Own.*

ANCIENT GARDENING IN ENGLAND.

"SUCH herbes, fruits, and roots as grow yéerelie out of the ground, of seed, have béné verie plentiful in this land, in the time of the first Edward, and after his daies, but in processe of time they grew also to be neglected, so that from Henry the fourth till the latter end of Henrie the seventh, and beginning of Henrie the eight, there was little or no vse for them in England, but they remained vnknown, or supposed as food more meet for hogs, and saugre beastes than mankind. Whereas in my time their vse is not onlie resumed among the poore commons, I meane of melons, pompons, gourds, cucumbers, radishes, skirrets, parsnips, carrots, cabbages, naueves, turneps, and all kind of salad herbes, but also fed vpon as deintie dishes at the tables of delicate merchants, gentlemen, and the nobilitie, who make their prouision yearly for new seeds out of strange countries, from whence they haue them abundantie. Neither doo they now stai with such of these frutes as are wholesome in their kinds but aduenture further vpon such as are verie dangerous & hurtfull, as the verangenes, mushrooms, &c., as if nature had ordeneid all for the bellic, or that all things were to be eaten, for whose mischievous operation the Lord in some measure hath given and provided a remedie."

"Hops in time past were plentiful in this land, afterwards also their maintenance did cease, and being now reuived, where are anie better to be found? where anie greater commoditi to be raised by them? onlie poles are accounted to be their greatest charge. But sith men haue learned of late to sow ashen keies in asbyards by themselves, that inconuenience in short time will be redressed.

Madder hath growne abundante in this Iland, but of long time neglected, and now a little reuived, & offereit it selfe to procure no small benefit vnto our countrey.

"And even as it fareth with our gardens, so dooth it with our orchards which were never furnished with so good fruit, nor with such varietie as at this present. For beside that we haue most

delicate apples, plummes, peares, walnuts, filberds, &c.: and those of sundrie sorts, planted within fortie yéeres passed, in comparison of which most of the old trées are nothing woorth: so haue we no lesse store of strange fruit, as abricotes, almonds, peaches, figges, corne-treees in noble mens orchards. I haue seen capers, orange, and lemmongs, and heard of wild olives growing here, besides other strange trees brought from afar, whose names I know not

"We haue in like sort such workemen as are not onlie excellent in grafting the naturale fruits, but also in their artificial mixtures, whereby one trée bringeth forth sundrie frutes, and one and the same fruit of divers colours and tasts. . . . Of hard fruits they will make tender, of soure sweet, of sweetes yet more delicate, beekeeing also some of their kernels, other of their cores, and finallie induing them with the saumour of muske, ambre, or sweet spices, at their pleasure. . . .

"What choise they make also in their waters, and wherewith some of them doe now and then keep them moist, it is a world to see; insomuch that the apothecaries shops seeme to be needfull also to our gardens and orchards, and that in sundrie wise; naine the kitchin itselfe is so farre from being able to be missed among them, that even the verie dishwater is not without some vse amongst our finest plants."—*Vol. I. of "Holinshead's Chronicles," edition of 1807, pp. 350, 353, of "Gardens & Orchards."*

The Name and Address of the writer are required with every communication, though not for publication, unless desired. Letters or inquiries from anonymous correspondents will not be inserted.

All questions on Horticultural matters sent to THE GARDEN will be answered by the best authorities in every department. Correspondents, in sending queries or communications of any kind, are requested to write on one side of the paper only.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

Readers who may find it difficult to procure THE GARDEN regularly through the newsagents, may have the numbers sent direct from the office, at 1s. 6d. per annum 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsagents, at the railway book-stalls, and from the office.

GREEN'S PATENT ROLLERS FOR LAWNS, DRIVES, BOWLING GREENS, CRICKET FIELDS, and GRAVEL PATHS,

Suitable for Hand or Horse Power.

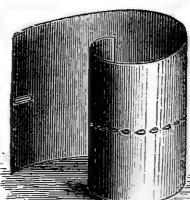

Illustrated Price Lists Free on Application.
THOMAS GREEN & SON, Smithfield Iron Works, Leeds,
64 & 65, Blackfriars Road, London, S.E.

NEW HARDY BEDDING PLANT, THYMUS CITRIDORUS AUREUS MAR-GINATUS (Lemon-scented Gold-edged Thyme), raised by FISHER, HOLMES, & CO. An exceedingly pretty Thyme, of an erect habit, with much branched habit, with large opposite leaves, which are of a bright dark green in the centre, and with a broad rich golden yellow margined variegation; is very handsome and attractive. It will prove very effective for edging flower beds, borders, or ribbon planting, and for growing in masses on banks, or in other varied forms; it may be grown as a winter bedding, having proved perfectly hardy. Although it may be considered as one of the most charming bedding plants known, and with the additional delicious fragrance of the sweet-scented Lemon Thyme.

It was exhibited at the Royal Horticultural Society on the 21st June, 1871, and received a First-Class Certificate; also at the Royal Horticultural Show at Nottingham a First-Class Certificate.

Rs. per dozen. 50s. per 100.

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE.—Shakespeare.

NOTICE.

The Conductor of THE GARDEN has commenced a tour of observation through the Gardens of England, beginning with the counties of Warwick, Worcester, and Stafford. Correspondents will greatly oblige by forwarding to him, at THE GARDEN Office, 37, Southampton Street, Covent Garden, London, W.C., information as to interesting gardens, remarkable trees, and other objects of horticultural interest in any of these counties.

THE FRUIT GARDEN.

PEACHES AND NECTARINES UNDER GLASS.

THESE are fruits deservedly esteemed by everybody, and although a considerable amount of attention is required to produce good crops of them, the result generally amply repays the grower for his trouble. For Peach borders, I prefer a strong fibrous loam, of a texture slightly adhesive, without manure of any kind, which I find apt to induce over-luxuriance. Previous to forcing, I thoroughly soak the borders in which the trees are growing with tepid manure water, which enriches the soil and stimulates the roots into action. Beginners should remember that a dry border is a frequent cause of the flowers dropping. A stagnant sour border, on the other hand, is equally injurious; aim, therefore, at what is termed the "happy medium."

I begin forcing with a low temperature; about 42° is a safe medium at night, because the slower the sap is put in motion the stronger the buds will break. With sunshine the thermometer will rise considerably, which will benefit the plants, if a free circulation of air is admitted and cold draughts avoided. I syringe the trees morning and afternoon till the bloom appears, admitting air freely in favourable weather, to secure strong and vigorous blossom, as Peaches and Nectarines are very impatient of close confinement. When the flowers are fully expanded, I increase the temperature to 50°, and discontinue syringing till the fruit is fairly set. A dry, close atmosphere being imminent to their requirements, I steam the flues and sprinkle the paths and borders to produce a moist healthy atmosphere. A close, high temperature whilst the trees are in flower, will result in failure. When the flowers are fully open, I make a point of aiding fertilization by distributing the pollen with a camel's-hair brush; a warm, nice gentle breeze also assists me greatly in the operation of fertilizing the bloom. When the fruit is set, I increase the temperature to 55°, syringe the trees as before, and apply tepid manure water pretty freely to the borders. I also gradually raise the temperature of the house at night, up to the stoning period, when it stands at 60°, and at that it remains until the stoning is completed. It is a waste of time and fuel to push them on beyond this point during the stoning process, as the fruit, although subjected to a temperature of any kind, makes little or no progress for three or four weeks. The trees themselves may be forced and growth greatly accelerated, but the fruit remains almost stationary, which shows the injudicious practice of over-forcing at this critical period.

Early and progressive disbudding is of great importance, for by it we avoid the practice of laying in too much wood, which must afterwards be cut out, thus exhausting the trees as much or probably more than the fruit they produce, and is one of the causes of barrenness or unproductiveness.

Thinning the fruits should commence when they are about the size of peas, removing only a few at a time, so as to cause no check, and reserving the final thinning till the stoning period is past, when they should be removed to their proper distances apart. Over-cropping should be studiously avoided, because it exhausts the trees, and injures them from carrying a crop next year. A safe rule is to allow one fruit for every ten or twelve inches of surface on a strong tree, but only about half this number on a weak one; and we shall find the decrease in number fully compensated for in the size and flavour of those left. The trees should always be kept scrupulously clean, and in a healthy vigorous state. To keep down aphis or green fly, slight and frequent fumigations with tobacco are much better than very strong applications.

If the roots of the trees are not duly supplied with moisture and food during the time the fruit is setting and swelling, failure of the crop is inevitable. When the fruits have commenced their second swelling, I increase the temperature to 65° by fire heat, but I am not fastidious to a degree or two. The inexperienced should be impressed with the idea that too much artificial heat and insufficient ventilation will cause a defect in colour and flavour. Every gardener who wishes to excel, is, or ought to be, ambitious to have high-coloured and well-flavoured fruits, thus enhancing their value; and the most effectual means to secure these effects are to be moderate with fire heat, allow plenty of solar heat, give abundant ventilation on all favourable occasions, and heavy tepid manure waterings to the borders whilst the fruit is swelling; but as it approaches maturity the manure water must, in all cases, be discontinued, or it will impart a bad taste to the produce. Syringing must also be withheld, and the borders allowed to get comparatively, but not completely, dry, otherwise the flavour will be affected. Throughout the forcing period, air should be admitted according to the state of the weather, and even during frost I find a little top air to be beneficial. I attach much importance to a top-dressing of leaf mould and decomposed manure in February, which prevents the drought penetrating to the roots of the trees, lessens the labour of watering, prevents too rapid an evaporation, and enriches the soil. Every means should be adopted to produce thoroughly ripened wood, as much of the success in Peach culture depends on this point. In the winter pruning, I reduce middling vigorous shoots one half, the weakest to two or three buds, from the main branch, and, if possible, to a treble eye, or where there is a blossom bud on each side of a wood bud.

By the above mode of treatment, I have been very successful in securing excellent crops of Peaches and Nectarines. I have two Peach houses, each eighty feet long and eight feet wide, heated by a brick flue. In 1868 I gathered from these two houses 106 dozen Peaches and Nectarines, and in 1870 upwards of 142 dozen, many of which exceeded eight ounces or half a pound each in weight, and they were highly-coloured and of surpassing flavour. In the present somewhat inclement season, most of my trees have set extraordinarily thick. In one house alone, I have removed as thinnings upwards of 1,500 fruit. I had the curiosity to count the fruits on about one square yard of surface of a Violet Hative Nectarine, and they exceeded three hundred; equally thickly set was a tree of Royal George Peach.

Many cultivators prefer their own treatment, to which I have no objection, provided it answers the purpose; for I am persuaded that Peach and Nectarine culture under glass resolves itself into this, that when a cultivator's practice is attended with satisfactory results, he should adhere to it as tenaciously as the ivy clings to the oak.

WILSON BOARDMAN.

SPAN-ROOFED HOUSES v. WALL PROTECTORS.

GARDEN WALLS and the protection of fruit trees on them, is a subject of great importance to gardeners, especially at this time, when we hear of such destruction of fruit blossom taking place in Yorkshire and in other localities by the snow-storms which we have lately experienced. I was probably the first who ventured to condemn garden walls as a protection for fruit trees; but every year's experience proves that I was right. Peaches, apricots, cherries, and the more tender sorts of plums, pears, and apples should be grown

Altringham.

in span-roofed houses; and the hardier varieties of apples, pears, and plums as standards, espaliers, &c., in the open borders, where they would not bloom so early as if trained on walls, and where most probably they would escape spring frosts. Trees planted out in a sheltered situation in this way do well, and the fruit is greatly superior in flavour to that grown on walls. Glass is the only effectual protection for fruit trees on walls. Mr. Ayres' protectors (see p. 476) I consider most efficient and ornamental; but I would say to those who contemplate making new gardens, do not build a wall at all when span-roofed houses can, in many districts, be erected at less cost than a brick wall with stone coping. The keeping of these houses in repair would not exceed the cost of repairing walls, providing temporary copings, canvas screens, &c. If this plan were carried out, it would be a great relief to gardeners, and the "everlasting" coping and other temporary coverings would be at an end. Last year was very disastrous to fruit trees, especially to those on walls; but had the trees been under permanent coverings such as I have described, the crop would have been saved.

Our climate is very variable and uncertain; as an instance of this I may mention what came under my own observation over twenty years ago, when in charge of a garden about seven degrees farther south than I am at present located. This season always brings it to my remembrance, and this very day (25th April) in particular. I had at that time as fine a wall of peaches as could be seen in the district. The fruits were as large as good-sized filberts, and the trees the picture of health. On the above date a sudden snow-storm came on from the south-east, which blew right against the trees, and from the violence of which old herring nets afforded no protection, as the snow could be taken off the trees in handfuls. The fall of snow was succeeded by a sharp frost, which completely destroyed the fruit, and the trees were so much injured that some of them had to be cut back, and others destroyed. This is doubtless only an instance of what others have experienced.

Lochgilphead.

J. R.

NOTES OF THE WEEK.

WE learn that in the neighbourhood of Moscow there has been a regular plague of mice, which have undermined both fields and orchards, destroying everything.

THE largest orchard in the world is said to be in California. It contains 426 acres, and more than 75,000 fruit trees. A good season in that country, it is reported, will produce as many as 20,000 oranges from a single tree.

THERE are still, we understand, eight million acres of unenclosed land in England and Wales; of these as many as three million acres lie in the lowland counties, at least one-third of which well deserves cultivation. When these million acres are enclosed, one-sixth of the whole acreage of England will still remain free and open country.

TRING PARK, Herts, comprising 3,643 acres, with a mansion seated in a deer park of 300 acres, together with the manor of Tring and the Royal grant by Charles II. of free warren and sporting over an additional 4,500 acres, and the exclusive right of fishing in the Tring reservoirs, was sold the other day by auction for the sum of £230,000 to Baron Lionel Rothschild.

THIS is reported to have been a trying season for trees and shrubs in the United States. The intensely rigorous frosts of March have proved too severe for many of the very hardiest kinds of evergreens; even rhododendrons, that thrive so well in mountainous districts where they are subjected to the keenest frosts, have sustained considerable damage. There are also heavy losses among conifers.

WE learn that vegetation is completely destroyed all round Vesuvius, which is now quiet, and the weather brilliant. Vast estates are completely ruined. It can hardly be believed that the soil trodden upon is that of *La Bella Napoli*. Orange groves, with their sweet perfume and rich vineyards, are all alike gone. Not a single flower has been left untouched to show forth the brilliancy of its colours. Houses and hamlets and gardens have been buried in burning lava.

AS an instance of expert workmanship, says the *American Agriculturist*, James Markey, one of Mr. Peter Henderson's men, can make more cuttings, or pot off more plants in the same time than any other man in America. It is good average work for one man to pot off in 2½-inch pots 2,000 cuttings in ten hours. Markey potted off in one day of ten hours, this spring, 7,000; while his average work of this kind is 5,000 a day. Of course, such ability commands its price, and Markey is paid quite twice that of most of his fellows. In market

gardening a man, planting cabbages or lettuces, with a boy to drop the plants, can set 6,000 a day; but John Scarry, also one of Mr. Henderson's old foremen, has repeatedly planted 10,000 a day. An average workman can tie 400 bundles of celery in a day, but mention is made of a market gardener who can tie up 1,200 in the same time.

— A LARGE specimen says the *Scotsman*, of Rhododendron Nuttallii is now in full bloom in a seed shop in Edinburgh. Though introduced into this country fully twenty years ago by Booth, who discovered it on the Bhutan Alps, it has as yet been rarely seen in flower. The species is interesting as having the largest flower of any known rhododendron. The leaves are from 5 to 8 inches long, and from 2½ to 4 inches wide, of a bright glossy green, and strongly reticulated on the under side.

— BESIDES the famous horse-chestnut tree which blooms yearly on or about the 18th of March, the Tuilleries gardens contain one of the numerous offspring of the willow planted on Napoleon's grave at St. Helena, which had been imported during the Second Empire. This willow, the pilgrimage of fervent Bonapartists, is at present dying, to the intense despair of all whom it interests. But it is to be hoped that the Administration will replace it secretly with another one which will answer just as well.

— DR. HOOKER, we understand, supports the project of a new Polar Expedition, on the ground of the immense service which it will render to botany. He proved the other evening, at a meeting of the Geographical Society, the extremely curious fact that Greenland had, in former times, a magnificent flora, and that maples, beeches, and other forest trees flourished there. He maintained that the disappearance of these trees, and the gradual substitution for them of the most miserable flora in the world, was a circumstance which would amply repay scientific investigation.

— AN EAST Indian tea expert, Mr. W. G. Howard, says *Hearth and Home*, has been successfully experimenting on the growth of tea in Georgia. He picked from one tea-plant twelve ounces of green leaf, which next day he made into three ounces of tea. This yield, he says, is fair ahead of that usual in India, where five hundred pounds is a fair season's yield from an acre. At the rate of yield in Georgia, he would procure 458 pounds at a single picking, and supposing he could get ten pickings—one every twenty days—the crop would amount to 4,580 pounds. The quality also is said to be excellent.

— SAYS a recent correspondent of the *Times*, before arriving at Jerusalem, taking a circumambulatory tour through the wilderness of Judea, by Solomon's Pool, Hebron, Bethlehem, Mar Saba, the Dead Sea, the Jordan, Jericho, and Bethany, I was struck with amazement by the herbal and floral clothing of the mountains and the dense foliage of the valleys, where in previous years scarcely a blade of green or a tiny flower could be seen. Our encampment in the valley of the Kedron, near Mar Saba, where last year all was sterility and barrenness, was this year amid the fragrant perfumes of a carpet of innumerable hues.

— THE SWISS *Times* reports that a fearful thunderstorm passed over Villmergen one day last week. From four o'clock in the afternoon it rained steadily, and about seven o'clock the lightning struck a cherry tree with a crashing report. Pieces of ten feet in length were found at a distance of one hundred yards. Of the stem no trace was to be seen, and the fragments of it, like those of the boughs, which were loaded with blossoms, were scattered in all directions. Half the root—a piece twelve feet long—was found some distance off with one end firmly planted in the earth. The meadow in which the tree stood looked as if some one had sown in it splinters and shavings.

— AT a meeting of the Corporation of London it was moved, as an amendment, "That the resolution of the 11th ult., agreeing with the report of the Markets Committee, in reference to Farringdon Market, be rescinded. And that it be referred to the Markets Committee to consider whether the present market could not be improved as a fruit and vegetable market at a moderate outlay. Also to consider whether, if it should be deemed expedient to build a new market at an outlay of £150,000 or more, the present site is the best one, or whether it would not be desirable to consider the advantages of some other site on the vacant land belonging to the Corporation, or some other land in the same locality? And, if thought desirable, to erect a new fruit, flower, and vegetable market upon any site, the committee be directed to advertise for plans, with an estimate of the expense, reporting thereon, from time to time, to this court." It was further moved, "that considering heavy commitments of the Corporation in reference to markets, it is most undesirable that a large outlay should be made upon Farringdon Market, until this court shall have had further time and opportunity for consideration. That the resolution of the 11th April be rescinded, and that the whole question of a vegetable, fruit, and flower market be referred to the Markets Committee for consideration, and to report fully thereon."

HARDY PLANTS IN FLOWER ROUND LONDON.

(DURING THE CURRENT WEEK.)

It is our intention to give weekly a list of hardy plants in flower in the neighbourhood of London. Such a record will be useful for reference, inasmuch as such selections may be made from it as will keep our outdoor gardens gay during every month in the year.

Adonis	Cerasus	Euphorbia	Lithospermum
vulgaris	cerasina	procera	pungens-purpureo-caeruleum
Aesculus	hippocastanum	Exochorda	leucon
rubiiflora	sylvatica	grandiflora	Lonicera
Jugla	Cherimanthus	Fothergilla	Ledebouri
repens and var.	alpinus	alnifolia	tatarica
Allium	Dillenii	Fritillaria	Xystocleum
odorum	Mitellii	Macleaggis	Lunaria
ursinum	schultzii	proxima	bipinnata and white
Alyssum	obcordatum	pyrenaicum	var.
genomenceum	montana	Forzio	Lupinus
leucadeum	Cochlearia	double and single	polyphyllus and
montanum	officinalis	Gentiana	vars.
orientale	Convallaria	germanica	Lychins
staceum	Polygalacatum	procumbens	Lagascav
spinosum	Corydalis	polystachys	syvestris plena
Wiersbeekii	eremoides	umbellata	var.
Amelanchier	Corydalis	Geranium	Marmolina
canadensis	bracteata	aconitifolium	discolor
vulgaris	capnoidea	angustifolium	obovata
Anchusa	lutea	cristatum	spectabilis
scutellarioides	Crategus	picroides	Yulan
Andromeda	floribunda	Forsternum	Malus
Androsace	hixiflora	sylvaticum and	biunciflora
chamaejasme	Cratagus	vars.	Malus
eximia	glandulosa	Globularia	melanocarpa
Anemone	macrantha	nudicaulis	Michauxii
alpina	oxyantha	tricolor	pedunculata
decapetala	tricolorantha	Gentian	Sorbus
hortensis	vars.	crassiloba	spuria
nemorosa pl.	prunifolia	Genista	Quercus
narcissiflora	Crinum	acaulis	Argilops

		rupicola	rosa
Rhododendron	var.	spongheimica	
		Lodigesii	

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

PRIVATE GARDENS.

Indoor Plant Department.—Conservatories are now gay with Azaleas, which are coming into flower without the aid of fire heat. In order to prolong their beauty, they are carefully shaded from bright sunshine. New Zealand plants, such as Boronias, Eriostemons, Pimeleas, Tremandas, Everlastings, &c., are now coming into flower, and are being nearly staked. These, as well as Hestias, occupy the coolest and most airy part of the conservatory. All plants in active growth receive plenty of water; and those done flowering are freely syringed, and have the benefit of a little artificial heat and shade. Azaleas, Rhododendrons, &c., done flowering are re-potted, pressing the soil rather firmly in the pots. Soft-wooded plants, such as Colosias and Balsams, are not allowed to receive any check from under-potting, but have plenty of root room whilst growing; a little bottom-heat and air being given them at the same time, also a little manure water. When it is desired to retard the flowering of Balsams, the flower-buds are picked off as they appear, until say a short time before they are required for use. A few Balsam seeds are also being sown in pans in gentle heat; as soon as the young plants appear, they are placed near the glass, and when fit to handle are potted off singly. Humesas required for conservatory decoration have now received their last shift, using for the purpose a compost of loam and well-decomposed manure. Stove plants, which are now making good progress, are allowed plenty of light, heat, and moisture; they are shaded from strong sun. Stephanotis, Allamandas, and Dipladenias have their shoots regularly trained as desired. Orchids making growth receive plenty of water, and such as are in flower are removed into a drier house than that in which they have been growing. Ferns are kept well shaded; paths, stages

and walls being kept moist by means of frequent sprinklings with water.

Pits and Frames.—*Polyanthus*, *Pansies*, and *Auriculas* are being raised from seed in cold frames, in boxes or pans. *Cinerarias* and *Primulas* are raised from seed sown in gentle heat. *Auriculas* done blooming and kept in frames, have the sashes removed; some are also placed out on sheltered places. The seed vessels of all, if seeds are not wanted, are removed. Seedling *Cyclamens* are kept near the glass in a moderately warm temperature; old plants producing seed are placed on shelves close to the glass in cool houses; some of the others are placed in cool, shady frames, or on a bed covered with ashes behind a north wall. Stocks are being re-potted; the best of the single ones are kept for seed. The propagation of bedding plants is now drawing to a close, except where the demand is in excess, and the pits or frames used for that purpose are now being converted into Cucumber houses. *Pelargoniums* are being hardened off by setting them in sheltered shady places, and those in frames by removing the sashes completely during the day, except in the case of the finer kinds of zonals and tricolors, which are still encouraged to make a little growth. *Verbenas*, *Calceolarias*, *Lobelias*, &c., are freely exposed, and, where convenient, are sheltered from heavy, cold rains.

Flower Garden and Shrubbery.—Shrubs are now gay with *Weigelas*, early *Rhododendrons*, *Ghent Azaleas*, *Berberis* of different kinds, scarlet and common *May*, &c.; masses of blue *Iris* and other herbaceous plants also set them off to advantage. Spring flower gardens are yet brilliant with *Heartsease*, *Trollolises*, *Daisies*, *Alyssums*, *Iberises*, *Wallflowers*, *Saxifrages*, *Tulips*, and various other plants. Preparation is now being made for bedding plants, and although many are reluctant to remove the fading beauty of spring for the more gaudy display of summer, they are convinced that unless this is done this month, summer droughts may overtake late-planted beds before their occupants get established. Indeed, in sheltered, warm situations, *Pelargoniums* have already been planted out. Flower beds are now being edged with *Gazania*, variegated *Arabis*, Japan *Honeysuckle*, and dwarf variegated grasses. *Violas* are also being divided and planted, as are likewise such plants as were divided and transplanted into nursery lines in February and March. *Polyanthuses* are divided and planted in lines; the soil for their reception having previously been enriched with fresh loam. Early spring flowering *Violets* are lifted, the offsets separated from the parents, and transplanted in lines twelve inches apart, a handful of sandy soil being placed around each root. *Sweet Peas*, *Tropaeolums*, and other annuals, raised from seed in beds, wall borders, or in boxes in frames, are now being planted out permanently.

Indoor Fruit Department.—Pines in active growth are now abundantly supplied with light, heat, and moisture, but as soon as they begin to ripen, watering is, to some extent, discontinued. Successions receive a little weak manure water, and the walls and the tan beds are syringed with the same. In the case of Vines, the fruit on which has done colouring, the temperature is reduced a little and the atmosphere kept rather dry. Pinching, thinning, &c., are being attended to in the case of later crops. Peaches and Nectarines passed the stoning period have the temperature increased to 65° at night, and from 80° to 85° during the daytime. The borders are well watered before the fruit begins to ripen; for if done afterwards the flavour is often deficient. Figs growing receive plenty of water at the roots and overhead; those ripening have the supply diminished a little; but not too much, as that would destroy the second crop. Cherry trees ripening off their crops are kept rather drier than usual, and when the fruit is gathered they are gradually hardened off, and after a time completely exposed. Melons have their laterals stopped, and where the fruit is swelling, if in frames, a piece of slate is placed under each; if in houses, they are allowed to rest on a piece of wood tied to supports with string. Cucumbers fruiting are supplied with a little manure water, and too many fruits are not allowed to remain on the plants at any one time; the syringe is also used freely amongst the foliage.

Hardy Fruit and Kitchen Garden Department.—Fruit trees making wood freely, are being stopped and thinned, so as to induce them to make an even and regular growth. Stone fruits on walls are thinned, and the trees syringed with tobacco water; all curled leaves are examined individually, and any insect pests present killed. Strawberries, now in full flower, are mulched with litter. French Beans are being sown on warm, light, rich borders. A full crop of Scarlet Runners is also being sown. Of Beetroot, the principal crop is now put in, and the produce of the first sowing thinned. Leeks for a late crop are being sown, and earlier ones transplanted. Parsnips are thinned, though at first not too much. Spinach is cleared off as soon as the leaves are gathered, and

another sowing made. White Dutch and White Stone Turnips are being sown, and the produce of former sowings thinned. A few Swede Turnips, for winter use and for tops in spring, are now being sown. Lettuces, Radishes, and other salad plants are sown in cool places. Savoys for late Crops are put in, and plants from former sowings of these, as well as Cabbages, Cauliflowers, and Kales, that are fit for the purpose, are being pricked out four inches apart. Beans are earthed up, and a late sowing of the Broad Windsor made. A few Cardoons are now sown, and also a few Carrots for drawing in a young state. Stems of Angelica are cut back, an operation which preserves the plants. On Asparagus beds that have been in bearing for some time, a few good shoots are left on each crown uncut. Trenches for early Celery are being prepared, plenty of decayed manure being dug into them. Potato crops are being hoed. Sprinklings of lime, sot, or sifted ashes are scattered over the ground in which young vegetables are grown, with a view to keep slugs in check.

NURSERIES.

Indoor Department.—Growing plants that have filled their pots with roots are being shifted into larger ones, and all that have been re-potted are subjected to a high and moist temperature, and well shaded. Plants of *Pereskia* from spring cuttings are now rooted and planted singly in pots, where, after they have got established, they will be used as stocks for Epiphyllums. In grafting Cacti, care must be taken to unite the inner, or concentric, circles of the stock with those of the scion. Young *Marantas* are being re-potted, as are also young plants of *Dracemas*, &c. *Ixoras* that have not been previously shifted this season, are now being re-potted into a compost consisting of leaf mould and peat, with a good admixture of silver sand. *Achimenes* started thickly in pans, are now transplanted into small pots, placing three or four roots in each pot. *Statice* continue to be propagated in cool pits. *Auricula* seed is being raised in cold frames. Seedling *Hollyhocks* are being potted off singly. *Lachenalias* done flowering are set outside in the shade. *Lily* of the Valley, forced in pits and remaining after the winter sales, are turned out, some into beds of ashes, and others plunged in lines to their rims in beds of soil. *Lilliums* are either kept in frames or plunged outside. *Gladioli* in pots are also plunged in open beds. *Chrysanthemums* are re-potted, the young plants being kept in cold frames, and old ones plunged in ashes outside. Hardy Ferns are kept in frames or placed outside between glasshouses. *Aloes* and *Yuccas* wintered indoors, are now set on ashes in sheltered places out of doors. All bedding plants are being turned out or into open frames.

Outdoor Department.—Suckers are being removed from grafted stocks as soon as they make their appearance. Hardy Conifers in the seed-beds are being loosened with steel forks, lifted, and transplanted in lines from six to twelve inches apart, according to size. *Magnolias* and *Prunuses* are being layered by fixing the branches down by means of strong wooden pegs, and covering over the portion under ground with a few inches of soil, allowing the points of the shoots to remain from six to ten inches out of the earth. *Magnolias* take a long time to root.

MARKET GARDENS.

EARLY Cucumbers in frames are now in good bearing; others are coming into flower, and some are still being planted in frames, and also under hand-lights on ridges. Litter is still kept around the frames, and some is also spread over them at night. Vegetable Marrows are protected with hand-lights and also with round baskets, around which litter is closely packed. Preparation is also made for another plantation of Vegetable Marrows by scraping the surface off Radish beds that have been drawn for market into the alleys, and digging it in, leaving the beds undisturbed. In every alternate bed holes about eight feet apart are taken out to be filled with fermenting manure, over which the soil will again be placed, the plants planted and covered with hand-lights, around which litter will be packed. Six or eight inch pots are filled with ordinary garden mould, and plunged to their rims in frames having a gentle heat; into these pots are planted with a dibber two young Vegetable Marrows as soon as they begin to form rough leaves. Tomatoes in pots, still kept plunged in frames, are now strong plants, and during all favourable weather the sashes are drawn completely off them. Kidney Beans are being sown in lines two feet apart, in open yet sheltered positions. Those of the first sowings have now appeared; before coming through the ground, the surface just over the seed was broken a little by means of small iron rakes. The first sowings were made amongst fruit bushes, and also on sheltered borders. In early spring, Shallot Onions were planted in lines eighteen inches apart, and little ridges of earth drawn over them; between every two lines so planted a space of three feet was left, and in this space a line of French Beans is now sown.

THE FLOWER GARDEN.

THE CASTOR-OIL PLANT.

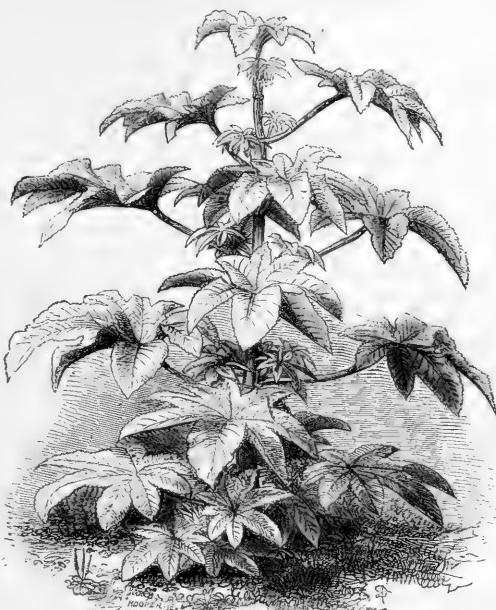

(*RICINUS COMMUNIS*.)

WHEN well grown in the open air, there is not in the whole range of cultivated plants a more effective subject than this. It may have been seen nearly twelve feet high in the London parks of late years, and with leaves nearly one yard wide. It is true we require a bed of very rich deep earth under it to make it attain such dimensions and beauty; but in all parts, with ordinary attention, it forms a noble object. In warm countries, in which the plant is very widely cultivated, it becomes a small tree, but is much prettier in the state in which it is seen with us—i.e., with an unbranched stem clothed from top to bottom with noble leaves. It is as easily raised from seed as the common bean, requiring, however, to be raised in heat. It should be sown about the middle of February, and the plants gradually hardened off so as to be fit to put out by the middle of May. The Ricinus is a grand plant for making bold and noble beds near those of the more brilliant flowers, and tends to vary the flower garden finely. It is not well to associate it closely with bedding-plants, in consequence of the strong growth and shading power of the leaves, so to speak. A good plan is to make a compact group of the plant in the centre of some wide circular bed and surround it with a band of a dwarfer subjects, say the Aralia or Caladium, and then finish with whatever arrangement of flowering plants that may be most admired. A bold and striking centre may be obtained, while the effect of the flowers is much enhanced, especially if the planting be nicely graduated and tastefully done. For such groups the varieties of the Castor-oil plant are not likely to be surpassed. It is also a grand subject for dotting amidst smaller plants in sheltered spots.

HARDY GLOIRE DE DIJON ROSES.

A FEW words on "Tea-scented Noisette Roses" for Camellia houses may be supplemented by some mention of Roses likely to play the same part out of doors. Good hardy white, yellow, buff (aye, and crimson—but of these anon) climbing Roses are a want. There is springing up quite a race of seedlings from Gloire de Dijon, from amongst which I would select the following as the best and most distinct. We all know our old friend Gloire de Dijon; but all do not know that it grows and does as well on a wall of northern aspect as when facing the sun. An amateur, whose little garden of Roses I should like to describe (his wife always ascribes his recovery from an illness to be due to a bunch of Roses the writer one day sent him in March, so you may guess how he loves them), has plants on east, south, and north-west aspects respectively, and from May to July these plants keep up in succession a perfect chorus of Gloire de Dijon. What say you to a first batch, on the south, of five hundred blooms, and so on? He gives plenty of nourishment, thus securing plenty of young wood, and his plants last for some years.

Well, first comes Gloire de Bordeaux, a rose-colour, with white

Castor-Oil Plant. Sketched at Berry Hill, September 1871.

smaller plants in sheltered spots.

shading on petals; few can bloom it; it does not like the knife, which some people use irrespective of habit. It is useful, but we would welcome a freer flowering rose. It reached us in two instalments (a guinea a plant each time), first as Gloire de Bordeaux, and the second time as Belle de Bordeaux; on examination, in the course of a year or two, both proved to be the same variety. Well, in 1869, some of our Lyons friends sent us some interesting seedlings of Gloire de Dijon. Our hopes were raised, and some turned out to be distinct. Belle Lyonnaise proves first rate; it loses the buff tint of Dijon, and is a deep-lemon colour, with the good habit of that variety. Madame Levet has a slight tint of violet sufficient to render it distinct. The others of that year are not to be recommended as distinct, so are not named.

Tour Bertrand has a slightly dwarfer habit, and may prove useful as a more compact headed standard Rose than its progenitors of 1870; and perhaps the best French Rose of last year is Madame Berard, a light salmon, with a fine reflexed petalled flower, and seemingly free in blooming.

Here are therefore five varieties, all hardy as their first parent, in colour buff, rose, lemon, salmon, tinted slightly with violet, and light salmon, with a distinctly-shaped flower. They are all worth growing.

G. PAUL.

THE SNAKE'S HEAD.

(*FRTILLARIA MELEAGRIS*.)

The pleasure of wild flower culture in the garden is greatly enhanced by the delight and excitement of discovery; I enjoy my white Bluebells and the double-flowered Ladies' Smock with much more zest on account of having discovered and unearthed them in their native homes, than if they had been introduced to my garden by the more prosaic means of ordinary purchase.

I first became acquainted with the speckled Fritillaria in the following manner:—Some of our village girls came on the first of May, a few years ago, to dance on the lawn in front of our cottage retreat, and I was much struck on observing that some of the garlands they carried were composed almost entirely of Fritillarias, one of them being wholly made up with the white variety of that pretty drooping flower. I eagerly inquired where they had gathered them, and was

informed that they grew in two old pastures not half a mile from the back of the village.

One day soon after I found myself in a meadow with great dots of dusky crimson here and there, which proved, on nearer approach, to be a profuse growth of the beautiful *Fritillaria Meleagris*, which I had never seen growing wild before, not even a single specimen, and here under my feet the flowers were as thick as Buttercups and Daisies, so much so that in a few minutes I had gathered as many as I could carry, and my somewhat sombre coloured bouquet was pleasantly varied by a few flowers of a white variety, which grew here among the dark ones, but not in the same profusion. This elegant wild flower might be said to resemble the Tulip in the shape of its bloom, but that instead of its stately and erect habit of growth, the drooping flower of the Fritillaria assumes a bell-like modest character. There are a good many species of Fritillaria, but all of them are exotic with the exception of *Fritillaria Meleagris*, generally known as the "common Fritillary." It has other popular names, one of which, Snake's Head, has doubtless been given in consequence of the peculiar colouring and shape of the bud. It has also been called the chequered Daffodil, from a slight resemblance in the bell-like form of its corolla to that flower.

The locality where I found my Fritillarias being literally empurpled with their hanging bells, I ventured to take up a few

roots and bear them home in triumph to our garden. The plants, both of the common form and the white variety, bore the transplanting to my garden without complaining, and several handsome patches have ever since continued to decorate the favourite borders of my wild garden, in which careful culture has made them surpass in beauty of form and luxuriance many of my regular garden *habitats*.

I have just lately visited meadows in various parts of Kent, which are literally carpeted with the richly sombre tints of this lovely flower, *Fritillaria*. I may add that this flower is not difficult to obtain in nurseries, and from which the bulbs may be easily transplanted when at rest. As a rule, it is best not to lessen the numbers of such uncommon wildlings.

G. C. H.

THE ALPINE GARDEN.

(Continued from page 497.)

ESSENTIALS IN THE CONSTRUCTION OF ROCK-GARDENS. POSITION.

The position selected for the rock-garden should never be near walls; never very near a house; never, if possible, within view of formal surroundings of any kind. It should generally be in an open position; and of course a diversified spot, or one with bold prominences, should be selected, if available. No efforts should be spared to make all the surroundings, and every point visible from the rockwork, as graceful, quiet, and natural as they can be made. The part of the gardens around the rockwork should be picturesque, and in any case display a careless wildness resulting from the naturalization of beautiful hardy herbaceous plants, and the absence of formal walks, beds, &c. No tree should occur in or very near the rock-garden; hence a site should not be selected where it would be necessary to remove valuable or favourite specimens. The roots of trees would be almost sure to find their way into the masses of good soil provided for the choicer alpines, and thoroughly exhaust them. Besides, as the choicest alpine flowers are usually found on treeless and even bushless wastes, it is certainly wrong to place them under trees or in shaded positions, as has generally hitherto been their fate. It need hardly be added that it is an unwise practice to plant pines on rockwork, as has been lately done in Hyde Park and many other places. In large rock-gardens rhododendrons may be planted, if desired, without letting them occupy the surface suitable for alpine vegetation. It will, however, generally be in good taste to have some graceful, tapering young pines within view, as this type of vegetation is usually to be seen on mountains, apart altogether from their great beauty and the aid which they so well afford in making the surroundings of the rock-garden what they ought to be. In small places, and in those where from unavoidable circumstances the rock-garden is made near a group of trees, the roots of which might rob it, it would be found a good plan to cut them off by a narrow drain, descending as deep as, or somewhat deeper than, the roots of the trees; this should be filled with rough concrete, and will form an effectual barrier.

CONSTRUCTION.

In no case should regular steps be permitted in or near the rock garden. Steps may be made quite irregular, and not only not offensive to the eye, but very beautiful; with violets and other small plants jutting from every crevice. No cement should be used in connection with the steps. Rockwork which is so made that its miniature cliffs, &c., overhang, is useless for alpine vegetation; and all but such wall-loving subjects as *Corydalis* soon quickly perish on it. The tendency to make it with overhanging peaks is everywhere seen in the cement rock-gardens now becoming rather common. Into the alpine garden this species of construction should never be admitted, except to get the effect of bold and distant cliffs, where that is desired and cannot be obtained in a more natural manner. When this system is admitted, the designer should be requested to obtain his picturesque effect otherwise than by making all his cliffs and precipices overhang. It is erroneous to suppose that heaps of stones or small rocks are necessary for the health of alpine plants. The great majority will thrive without their aid if the soil be suitable; and though all are benefited by them, if properly used as elsewhere described, it is important that it should be generally known how needless is the common system of inserting mountain plants among loose

stones, burrs, &c. Half-burying rocks or stones in the earth round a rare species, which it is intended to save from excessive evaporation, and which has a deep body of soil to root into, is, however, quite a different and an excellent practice.

MATERIALS.

As regards the kinds of stone to be used, if one could choose, sandstone or millstone grit would perhaps be the best; but it is seldom that a choice can be made, and happily almost any kind of stone will do, from Kentish rag to limestone; soft, silty, and other kinds liable to crumble away, should be avoided, as also should magnesian limestone. It can hardly be necessary to add that the stone of the neighbourhood, if not very unsuitable, should be adopted for economy's sake, if for no other reason. Wherever the natural rock crops out, it is sheer waste to create artificial rockwork instead of embellishing that which naturally occurs. In the Central Park at New York there are scores of noble and picturesque breaks of rock, which have not been adorned with a single alpine flower or rock bush. Something of the same kind might be said of many of our country seats. In many cases of this kind nothing would have to be done but to clear the ground, and add here and there a few loads of suitable soil, with broken stones, &c., to prevent evaporation; the natural crevices and crests being planted where possible. Cliffs or banks of chalk should be taken advantage of in this way, as well as all kinds of rock; many plants, like the dwarf campanulas, rock roses, &c., thrive vigorously on such places. No burrs, clinkers, vitrified matter, obscene crockery, portions of old arches and pillars, broken-nosed statues, &c., should ever obtain a place in a garden devoted to alpine flowers. Stumps and pieces of old trees are quite as objectionable as any of the foregoing materials; they are only fitted to form supports for rough climbers, and it is rarely worth while incurring any expense in removing or arranging them. Begin without attempting too much. Let your earliest attempts at "the first great evidences of mountain beauty" be confined to a few square yards of earth, with no protuberance more than a yard or so high. Be satisfied that you succeed perfectly with that before you try anything more ambitious. Never let any part of the rock-garden appear as if it had been shot out of a cart. The rocks should all have their bases buried in the ground, and the seams should not be visible; whenever a vertical or oblique seam of any kind occurs, it should be crammed with earth, and the plants put in will quickly hide the seams. Horizontal fissures should be avoided as much as possible; they are only likely to occur in vertical faces of rock, and these should be avoided except where distant effect is sought. No vacuum should exist beneath the surface of the soil or surface-stones. The *detritus*, &c., should be so disposed that a vacuum cannot exist. Myriads of alpine plants have been destroyed from want of observing this precaution, the open crevices and loose texture of the soil permitting the dry air to destroy them in a very short time.

In all cases where elevations of any kind are to be formed, the true way is to obtain them by means of a mass of soil suitable to the plants, putting a rock in here and there as the work proceeds; frequently it would be desirable to make these mounds of earth without any strata or "craggs." The wrong and the usual way is to get the desired elevation by piling up arid masses of rock.

The surface of every part of the rock-garden should be so arranged that all rain will be directly absorbed by it; here, again, the objection to precipitous and overhanging faces holds good. If the elevations are obtained, as they should be, by gradually receding, irregular steps, rather than by abrupt crags, walls, &c., all the plants on the surface will be equally refreshed by rains. The upper surfaces of crags, mounds, &c., should in all cases be of earth, broken stones, grit, &c., as indeed should every spot where projecting stones or rock are not required for the sake of effect. All the soil-surfaces of the rock-garden should be protected from excessive evaporation by finely broken stones, pebbles, or grit scattered on the surface, or by means of small pieces of broken sandstone or millstone half buried in the ground.

(To be continued.)

A CHINESE NARCISSUS.

("THE GRAND EMPEROR.")

NOTICING that one of your contributors is interested in collecting facts about varieties of Narcissus, I think it possible that what I have to offer may be new. Some of the Chinese who have been tempted by high wages to emigrate to this country have brought with them a few bulbs of a Polyanthus Narcissus, which they call the "Grand Emperor." Its growth seems to me remarkable. Two bulbs which came into my hands about the first of January, threw up shoots more than two feet high before the end of the month; and by the middle of February there were five or six stalks from each bulb, all in blossom. I do not think I should be able to distinguish a stalk of these flowers from one of the Staten General, except by its length; the flowers appeared to me to be exactly similar to those of that well-known bulb, but as I had not any of the latter in bloom at the time, I could only depend upon memory in this comparison.

But its rapid and tall growth is perhaps less remarkable than the treatment this Narcissus requires. I was specially cautioned by the Chinese from whom I received the bulbs that no earth must be used in "planting" them. They were simply to be covered with water, which was to be renewed every day. Some clean pebble-stones might be piled on them to keep them from floating. All further care was to consist in giving them light and keeping them from frost. I complied with the instructions, except that I substituted bright sand for pebbles; and I was fairly successful, for although a few buds failed to mature, I had an abundance of flowers, the offsets as well as the bulbs producing flowering stalks. Preferring to watch their growth in transparent pots, I was very much puzzled to find suitable glass vessels for them, but at length discovered that the "battery cups" of a telegraph apparatus were exactly what I wanted. The plants are now about three feet high, and the leaves are green, showing no signs of dying down, though the flowers are long since dead. As I was instructed to keep the bulbs wet and not to plant them in earth, I begin to think they may prove troublesome in the coming summer, if they are to be ever thus.

There is a Chinese legend which accounts for the "origin of species" as regards this Narcissus. It seems that once upon a time a father left his property to two sons, with the understanding that it should be equally divided; but the elder son seized all the tillable land and left the younger nothing but an acre covered with rocks and water. The younger son, unable to obtain justice, sat down at the water's edge, bemoaning his misfortune. A benevolent fairy appeared, and giving him these Narcissus bulbs, told him to drop them into the water. Shortly afterwards their flowers were developed, and neighbours crowded to admire the fairy gift. In the course of a few years he accumulated a fortune by the rapid increase and sale of his bulbs. Then the elder brother, envious of the younger's prosperity, bought great numbers of the bulbs—hoping to obtain a monopoly by getting all of them—at so heavy an expense that he was obliged to mortgage his property to procure funds for the purchase. He planted all his land with the bulbs. They soon began to die, as they cannot live long out of water. He was ruined, while his brother, who had bought the mortgage, foreclosed it, and became possessed of the whole estate in time to re-plant some of the dying bulbs in the watery acre.

Nevertheless, I put down one of the offsets in damp garden soil some weeks ago, and at present it is still flourishing.

P.

New York.

CULTURE OF SPRING-FLOWERING PLANTS.

Now, before they finally leave us, seems an opportune moment for saying a few words on the treatment of these. All enjoy the sweeteness and beauty of the Violet, Primrose, Forget-me-Not, Aubrietia, Arabis, &c., but comparatively few have yet learned that the foundation of that beauty must be laid presently if a bountiful harvest of it is to be reaped next spring. Each tuft must be divided into single stems, hearts, or runners, and these tiny bits planted in good soil in the open border to insure patches from six inches to a foot wide, bristling with flowers in embryo next October. Even Daisies should be separated into single crowns if they are to bloom in perfection next year. In regard to Violets, only the runners rooted, on the plant or off, should be saved. The old plants, if divided even, never blossom so profusely a second time; while as to leaving them undisturbed to flower again, is a mere waste of ground, as they will only yield tens of flowers to hundreds borne on the young plants. The same rule holds good with all such running plants as Arabis, Aubrietia, and Candytuft. Annual subdivision and liberal culture throughout the summer months are the ways to make the best of them.

There are a few exceptions possibly to this rule of annual subdivision. That grand golden plant the Alyssum saxatile flowers best the second season after subdivision, and will go on flowering grandly in the same spot until a single plant covers a yard or more of ground round into a veritable miniature Field of the Cloth of Gold. Iberis sempervirens again, and some of the Saxifragas, do likewise, though they also bear division well. On the other hand, Myosotis dissitiflora is comparatively poor and apt to lose its heart if left two years in one place without complete subdivision. The fact is, that where spring gardening is carried out on a large scale and to any degree of perfection, a supplementary staff and a reserve garden are requisite. This must be borne in mind by all who would have their gardens filled with beauty from February to May. As well expect to gather grapes off thorns as to reap a harvest full of spring beauty without preparing the plants for it by previous culture. The spring sun only loosens and brings forth those treasures of sweetness and charms of colour that the winter frosts had barred in; but the fragrance and the glory are the products of the previous summer's sunshine, its balmy airs, soft dews, and refreshing rains. As we sow so shall we reap.

D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Native Heaths.—*Erica vagans* and its varieties are among the best growers, and soon become large plants. They can be trained, or rather cut, to any shape, and would be useful ornaments in many spots in our gardens.

Eccremocarpus scaber.—Among neglected and unappreciated plants may be mentioned *Eccremocarpus scaber*, a pretty little tree, and a rapid grower, producing spikes of orange-coloured flowers in profusion. The price of it is what it bears is incredible. Last June I sowed some, the produce from which remained green through the winter, and in February blossomed sparingly; no seeds resulting, blossoms have appeared at intervals ever since. My garden is on one of the highest hills in Kent; aspect, due east.—BOTANY COTTAGE.

Arabis blepharophylla.—I have now a bed of this beautiful and most modest rock crevix in full bloom. Like *Myosotis dissitiflora*, it has had the edge taken off its beauty by the late sudden and severe frosts and snow-storms, but it is still a very effective mass of magenta, and quite unique in its way; it seems to like a dry, chalybeate Buckinghamshire soil, almost rivaling its congener, *Lunaria biennis*, in the size of its blossoms. It seeds freely, and also strikes readily from cuttings.—H. HARPER CEWEZ, *The Rectory, Drayton-Beauchamp, Tring*.

Camellias and Myrtles in Leicestershire.—We are often apt to associate myrtles and, above all, healthy bushes of camellias in the open air, with the balmiest sea-coast districts. Few would suppose it less than folly to plant such subjects in the open air in the midland counties; yet at Belvoir the other day we saw a fine specimen of the latter, half a dozen feet high, in glorious flower as they are in Devonshire. They grow on the elevated slopes, well sheltered by surrounding shrubs and trees. Of course, similar success could not be hoped for in low-lying and exposed grounds. It is the elevation, with the shelter, which accounts for the success. These conditions occur frequently, without advantage being taken of them.—W. R.

Rose Showings.—I intend competing at a flower show, and there are offered prizes for the best light rose and best dark, and I wish to ask the Rev. Reynold Hole if I might show Madame de Cambacérès or Coupe d'Hebé as light roses. I never had any doubt about them being light roses myself; but to a friend who asked me to let me know my intentions about showing them in the light class, and himself said he could disqualify it if I did, as they are not light roses, I certainly should never think of showing them as dark, as, according to M. Jacquemelin, Fisher Holmes, &c., to represent the dark class. In his book on roses, Mr. Hole says, avoid using leaves help to set them off, as they would be disqualified. The schedule belonging to the society's show at which I intend to compete, says buds and foliage will be allowed; would it make any difference, then, that the collection was smaller, if I used foliage as allowed in this schedule?—W. R. Y.—*Editor of the Horticultural Magazine*.

Madame de Cambacérès' rose, mentioned above, is usually shown as "light" roses, but such varieties as the Baroness Rothschild, Marguerite de St. Amand, La France, Mille Eugénie Verdier, Madame Vidot, Madame Rivers, Miss Ingram, Devonensis, &c., would be much more likely to win the prize alluded to. If additional foliage is allowed in the schedule, and the flowers shown are not naturally accompanied by ample and healthful leaves, let advantage be taken by all means of the permission given.]

Hardy Variegated Plants.—We may safely predict that in a very few years we may produce the grandest effects on our patios with such of these plants as bear the open air in grand style, at least with the protection of a cold, frame during the winter period. The will be a revolution in flower gardening, and will vastly lessen the labour of the flower gardener, who, I suspect, I do not know how many thousands of tender exotics, often with means totally inadequate. The greatest want of the hardy flower gardener is a suitable reserve ground with a few cold frames for propagation, increase, and protection of the choice species and varieties, some of them equaling if not surpassing in beauty many varieties of tender plants fostered in our stoves and greenhouses. The *Primula* and *Primula* *farinosa* are a few examples which, when exposed to little unprotected nursery beds for the increase of this class of plants is also very desirable. They are becoming very popular, and are within the reach of peasant as well as peer. From what I can see of our native plants, the variegated forms of them are inimitable. I have seen a dock (*Rumex crispus*) so handsomely variegated that I shall not be far wrong in stating that it is as handsome a hardy plant as ever was introduced. The form is in the form of a large yellow leaf, and as ever as the surface of the leaves is white, pale, and, as lovely as any Crocus. I have seen it in our stove. If this comes from seed, it must become a general favourite. One of the finest plants for marginal effects is another British plant, and only a "nettle" (*Lamium maculatum aureum*). This is more adapted for shady situations than in the full sun or it would have proved a formidable rival to Henderson's Golden Feverfew, and I assert that when well grown it beats anything else for an edging of gold. During the summer season it has a distinct orange tint; this, combined with the white stripe up the centre of each leaf, renders it at once most brilliant and unique.—W. E.

PUBLIC GARDENS.

THE CENTRAL PARK, NEW YORK.

(Continued from p. 525.)

It is pleasant now to turn to the many charming features of this noble national garden. Although its oblong shape, and the immense space occupied by the stiffly outlined reservoirs that supply the city with water, were in the way of very great breadths of turf being formed, yet the designers deserve great praise for the happy manner in which they have succeeded in creating large and pleasant lawns.

Another admirable feature is the way in which certain roads are carried across the park. There are four of these transverse roads in its whole length: one at Sixty-fifth Street; another at Seventy-ninth; a third at Eighty-fifth Street, on the Fifth Avenue, but as it follows the curved southern wall of the new reservoir, this road comes out at Eighty-sixth Street on the Eighth Avenue. The fourth road is at Ninety-seventh Street. The original instructions to the competitors called for these transverse roads; but none of the designs, except Mr. Olmsted's, the designer of the park, offered any solution to the very serious problem presented by the necessity of making provision for the traffic that must at some day be provided with roadways across the park, and which must yet, at the same time, be prevented from interfering with the objects for which the park has been created. All the other competitors merely carried their transverse roads from one side of the park to the other, on the surface, keeping the same level with the other roads, and

Native Oaks in Central Park, New York.

not in any way distinguished from them. Of course, such an arrangement as this would have even now been sufficient to interfere seriously with the comfort, the retirement, and even the safety of the park.

The trees in the parks are nearly all young. There were few trees of any importance in the place originally; of these, however, the best were preserved, and among them the group of native oaks illustrated above. The planting is, as a rule, well varied and well arranged.

It has been several times proposed to establish in the park a formal arboretum, or a scientifically arranged botanical garden. But, to our thinking, it is quite as agreeable a way of studying the different varieties of plants, and trees, and flowers, to find them scattered naturally over the whole park, as it would be to have them planted more scientifically in rows and squares, as for convenience of classification and reference they must be in a botanic garden. For our part we like to come upon these pretty strangers unawares; to catch them, as it were, off their guard, rather than to go through the formalities of an introduction. Rather, in this particular case, make the whole park a botanical garden, giving each plant as far as possible its native habitat and surroundings, and fixing near it, in a quiet, informal way, a label with its name. The scientific man and the poet can then enjoy it, each in his own way.

The park is distinguished from any we have seen in Europe by often happy attempts to introduce such features as bird-houses, a dairy, and various other structures, very suggestive

of rural life; most conspicuous among these being well-constructed shade or summer-houses, one very large one of which, called the viney, is shown below. The warm climate renders such structures very agreeable, if not absolutely necessary.

The material employed in the construction of these structures is the common American cedar, which abounds in the vicinity of New York. The limbs and trunks are stripped of their bark, and they are then put together in a solid and

The Vinery, Central Park, New York.

workman-like fashion, very unlike the frail and flimsy structures which we commonly meet with under the name of summer-houses. Nor is it merely the workmanship that make them noticeable—the design is always artistic and agreeable, and they are no less an ornament to the park than useful and convenient buildings, without which the place would lose one of its chief attractions. Nearly all of them are now covered with vines which, in many cases, almost conceal the frame-work, giving us, instead of artificial decoration, a profuse tracery of the most graceful creepers. Over some, the Chinese Honeysuckle spreads a fragrant shade; over others the Wistaria, with its parti-coloured leaves of tenderest brown

Summer-House in Central Park, New York.

and green, and its delicate lilac flowers; or the rampant Trumpet-creepers, that with the larger, and that with the smaller and finer flowers; or the wild grape with its spring-scent sweeter than mignonette; or the pretty gourds with their pendent bottles of yellow, green, and orange, the delight of children.

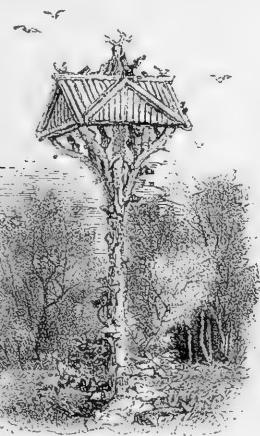

The only objection we could see to such structures was that they were often too much exposed to view, and occupied positions of too great importance to be given to any such structures. A great many of the smaller type of summer-houses may also be seen. They are, however, usually so well and tastefully built that they do not fail to please. They will look very much better when time or the gardener clothes them with the wild grace and loveliness of climbing plants.

Among other rusticities of this sort are the boat houses, the swan rests, the houses for English sparrows, and the various strong and very prettily arranged rustic bridges. The

Rustic Bridge in Central Park, New York.

sparrow, pelted from the ivy, and mercilessly dragged out of the caves with us, here finds himself provided not only with a house, but with a palace. Here he may increase and multiply in peace, and by his vigorous and successful onslaught on the hordes of ugly caterpillars with which the trees in New York used to swarm, he has well rewarded the New Yorkers for their good treatment of him. There is a rumour, however, of

English Sparrow House in Central Park, New York.

Mr. Sparrow fighting with and exterminating some of the American songsters, and, if so, he may some day be deprived of his lordly dwelling, especially if in the meantime he should succeed in exterminating the "measuring worm," enemy of trees, and of tree-loving and shade-haunting men. Swans have been presented to the park by the City of London and Hamburg, and now thrive there.

(To be continued.)

THE LIBRARY.

BOTANY FOR BEGINNERS.*

A PRETTY little volume, well illustrated, and clearly written by one of our most accomplished botanists. Happy should be the little budding botanist in having such a good and simple guide as this. The most zealous students, as Dr. Masters remarks, not unfrequently chafe at the irksome task of making themselves acquainted with a series of abstract propositions, couched in harsh unfamiliar language, and whose significance they are unable to appreciate. An attempt has therefore been made in "Botany for Beginners" to correlate these details from the first, and to give the pupil an interest in them, by making manifest to him their importance in illustrations of the principles of plant-construction. The simplest flowers have been chosen as examples in the first instance; afterwards others of more complicated construction have been selected. An effort has been made in each case to show how and why the various modifications have been brought about. The life-history of the several plants has been incidentally touched on, and occasional hints have been furnished with a view to show the real aim and scope of botanical science, concerning which many students hold far too limited views.

We heartily recommend this book to all who want a pleasant and accurate guide to elementary botanical knowledge.

THE FAIRFIELD ORCHIDS. †

WE have before us a well-printed, neatly-bound volume of 128 pages devoted to the general history, culture, and description of the Orchidaceous plants cultivated by James Brooke & Co., at their nurseries, Fairfield, near Manchester. This useful little work is the result of a well-directed attempt to elevate the tone and introduce strictly correct and reliable information into a trade catalogue, and if we judge it from the latter stand-point we must confess that it is the best issued by any nurseryman up to the present date. It is, however, something more than a mere catalogue; it contains a good deal of sound practical cultural information, together with able and lucid descriptions of between three and four hundred species and varieties of the best garden orchids, with date of introduction, native country, season of flowering, duration of the flowers themselves, and other information interesting both to cultivator and exhibitor.

We could have wished it had been carried out still further, however, since we find one or two genera omitted which are just now deservedly popular with orchid-growers; as *Masdevallia*, for example, a lovely genus of cool orchids from the highlands of the New World. Again, many good showy species are omitted which might with advantage be added in the future editions through which we hope this instructive work will pass. We notice one or two irregularities; notably one at the foot of page 79, where the author has been singularly unfortunate in selecting illustrative examples of the yellow-lipped *Odontoglossum*; since all cultivators will agree with us that both *O. lavea* and *O. bictonense* have white lips, or rather lips the ground colour of which is white, certainly never yellow; and on referring to the specific descriptions of the two species named (see p. 80 and p. 82), we find the author there himself admits that they have white grounds.

The latter part of the volume contains valuable glossary of generic, specific, and descriptive terms used when speaking of these beautiful plants, besides some useful general information connected therewith. We add a short extract to give an idea of the information given, and wish this handy little volume all the success which it deserves:—

"**LIMATODES.**—Ground orchids, natives of India and Java, and in structural characters nearly allied to Calanthe. 236. *L. rosca* [a.b], Moulnmein, in the Province of Martaban, 1850. Leaves oblong-lanceolate, plaited, and deciduous. Scape erect, ten inches high, bearing a raceme of many loosely placed and deep rose-coloured flowers two inches across. A sparkling and delightful species, presenting all the features of a Calanthe (with the addition of long and fusiform pseudo-bulbs), blossoming in winter very abundantly, and easily grown. 10s. 6d. *Bot. Mag.*, 88, 5,312; *Part. Fl. Gard.*, 3, 81."

* Botany for Beginners. An Introduction to the Study of Plants. By Maxwell T. Masters, M.D., F.R.S., late Lecturer on Botany at St. George's Hospital, London: Bradbury, Evans, & Co.

† "The Fairfield Orchids. A Descriptive Catalogue of the Species and Varieties of Orchids Grown by J. Brooke & Co., Manchester.

THE INDOOR GARDEN.

GESNERAS.

To all who wish to provide for a fine and not too evanescent autumn and winter bloom, these lovely and stately plants are invaluable; and no time should now be lost before laying the foundation of the hoped-for harvest of brilliant blossoms. In point of treatment the Gesneras are not exacting, the chief requirements being a rich open vegetable soil, a bottom heat of 75° to 80° to start them into growth, a moist atmospheric temperature of 65° rising to 80° , with sun heat and partial shade, in bright weather. Provide these conditions and success in cultivation is certain. For the purpose, however, of having a continuous succession of bloom the plants should be started at three different times, say the early part of April, May, and June—a sufficient number of bulbs being put in on each occasion to furnish the plants you may require at each period. Those started into growth first will come into bloom by the end of September, and the others will follow in succession through the winter and spring.

The bulbs should be planted entire, placing one in each small pot, when they are to be bloomed in four or six inch pots; but three, five, or seven bulbs when plants of larger dimensions are required. For soil, take fibrous sandy loam two parts, broken so as to pass through an inch meshed sieve, and with the fine soil sifted out, leaf mould one part, and turfy peat, broken small, in the same proportion. To each peck of the preceding ingredients add a pint of silver sand, and about the same quantity of charcoal, broken to the size of horse beans. Mix these intimately together, and the compost is fit for use. Then procure the requisite number of clean three-inch pots, drain them properly, fill lightly, and press into each one or more bulbs, as you may decide to grow them, leaving each bulb about half an inch below the level of the soil. When the variety is scarce, or a large quantity of plants is required, each strong bulb may be broken into four or five pieces. Thus broken, they will not start so quickly into growth, but still they will start and make good plants. After potting, plunge the pots in a botched of 80° , and, until the young plants begin to show through the soil, keep the soil moist, but not wet. As the plants progress in growth, they must be shifted into larger pots, using the same compost, and they must receive the moist atmospheric temperature before indicated.

As Gesneras are very liable to burn, it is particularly necessary that they be shaded early by a piece of very thin net, or, what is better, and what will prevent the possibility of injury from neglect, wash the glass, under which the plants are placed, quite clean, and when quite dry, coat it thinly with boiled linseed oil. This will stand for a season, and in the autumn may be washed off with strong soda water. As the plants progress in growth they will require to be shifted into larger pots, always using the same compost, and pressing it quite firmly. For the largest specimens, pots eleven to fifteen inches in diameter may be required, but for these, pans of about nine inches deep, and of the necessary size otherwise, are the best. Maintain a mean atmospheric temperature of 70° throughout the growing season, but, as the plants begin to show bloom, the temperature may be gradually lowered, and 55° to 65° should be the medium through the blooming season. More than this will cause the flower stems to be drawn and the flowers to drop prematurely; neither will they attain so fine a colour. The atmosphere of the house through the winter should not be moist, but rather dry. Thus managed it will be found that plants of *G. exoniensis* will maintain a "blaze of bloom" for three months in succession. We have said nothing of liquid manure. That prepared from sheep or cow dung and soot, clarified by throwing a lump of lime into it, may be used weak and warm at all times after the plants are thoroughly established and the pots full of roots. Take care, however, that it is weak; and in order that we may not be mistaken, we may say that a quart of the prepared liquid thrown into a gallon of clean soft water will be ample for repeated use. F.

A REVISION OF THE GENUS DRACÆNA.

BY DR. REGEL.

This noble genus of fine-leaved plants is now becoming so deservedly popular that the following revision of it by Dr. Regel, cannot fail to be useful to all who take an interest in them:—

DRACÆNA UMBRACULIFERA.

Stem simple, erect, sometimes seven feet high; leaves sessile, half-clasping, those on the top of the stem forming an umbel, drooping, elongated linear-lanceolate, 1 inch to $1\frac{1}{2}$ inch broad, 2 feet to 3 feet long, with a prominent nerve in

the middle on both sides, and striated with fine longitudinal veins or nerves; panicle terminal, very short and densely corymbose; flowers red on the outside, white inside, of a long tubular shape (the divisions of the corolla being less than one-fourth of the length of the tube), with short and thick flower-stalks, and arranged in fascicles on the ends of the branches. Native of the Mascarene Islands.

Synonyms—*Cordyline umbraculifera* (Fl. d. Serres).

DRACÆNA ARBOREA.

Stem simple, thick; leaves crowded together at the top of the stem, recurved-patent, sessile, clasping, narrowly lanceolate, $2\frac{1}{2}$ inches to 3 inches broad, 2 feet to 3 feet long, parchment-like, with a thick prominent nerve in the middle on both sides, with small longitudinal folds and nerves of a shining green on the upper surface (margin of the same colour), and often marked with darker anastomosing small veins. Native country and flowers unknown.

Synonyms—*Aletris arborea* (Willd.), *Dracaena Knerckiana* (C. Koch).

DRACÆNA ANGUSTIFOLIA.

Stem erect, simple or branching; leaves crowded together at the top of the stem and branches, sessile, erect-patent, linear-lanceolate, 1 inch broad, $1\frac{1}{4}$ to $1\frac{1}{2}$ foot long, with a central nerve on both sides which is very prominent on the under side, striated with veins; panicle terminal, simple, erect, with loosely racemose branches. Flowers in fascicles of two to five blooms, with scarious bracts, which are shorter than the slender flower-stalks. East Indies.

DRACÆNA FRUTICOSA.

Stem shrubby, with leaves only at the top; leaves sessile, linear-lanceolate, 2 inches broad, 17 to 20 inches long (according to Rumph., but only 12 or 13 inches in the specimen which I have seen), with a conspicuous midrib on both sides, stem-clasping, concealing the internodes with their bases; panicle simple, terminal, with loosely racemose branches; flowers in pairs or solitary; bracts scarious, ovate, acute, shorter than the pedicels; style as long as the stamens. Java. The specimen which I have seen was gathered near Pellowa (Pegu).

Lamarck considers the *Terminalia angustifolia* of Rumph. identical with *Dracaena reflexa*, but the latter is a very different plant, as the internodes are not concealed by the bases of the half-clasping leaves. *Dracaena fruticosa* of Blume comes very close to *D. ensifolia* of Wallich and D. *Kochiana* of Regel, but they are easily distinguished, as the former has narrower and shorter leaves which cover the stem entirely or as far as the middle; flowers in threes or fours, and the style longer than the stamens. In the latter the leaves are slightly margined with red, and the bracts are of a violet colour and as long as the pedicels.

Synonyms—*Sansevieria fruticosa* (Blume), *Terminalia angustifolia* (Rumph.).

DRACÆNA FRAGRANS (GAWL.).

Stem tree-like, branching, 15 feet to 20 feet high, clothed with leaves from the base to the top, or from the middle to the top; leaves sessile, clasping, recurved-patent, lanceolate, $2\frac{1}{2}$ to $3\frac{1}{2}$ inches broad, $1\frac{1}{2}$ to 2 feet long, slightly undulated, with a midrib sunken on the upper surface and prominent on the under-side, and striated with fine nerves; panicle terminal, nearly erect or recurved, bent at the joints; branches divaricately-patent; flowers in dense racemose heads and very fragrant. Guinea and Sierra Leone.

Synonyms—*Aletris fragrans* (L.), *Sansevieria fragrans* (Jacq.), *Cordyline fragrans* (Fl. d. Serres).

DRACÆNA KOCHIANA (RGL.).

Stem shrubby, erect, simple or branched, clothed with leaves at the top; leaves sessile, patent-recurved, leathery, narrowly linear-lanceolate, attenuated, acute, about $1\frac{1}{2}$ inch broad, and sometimes as much as $1\frac{1}{2}$ foot long, with a stout midrib which is sunken in the upper surface of the leaf and prominent on the under surface, striated with fine veins, and with a faint red margin which in some specimens is hardly visible; panicle terminal, simple; flowers crowded together in threes, and accompanied with violet-coloured bracts of the same length as

the pedicels. Native country unknown. I have seen a specimen in cultivation.

Synonyms—*Dracena arborea* (C. Koch.), *Dracena fruticosa* (Hort. Berol.).

(To be continued.)

PALMS FOR THE GARDEN.

(Concluded from p. 462.)

THRINAX.—An elegant and useful genus, belonging to the fan-shaped section, the foliage being compact, and more graceful than that of *Chamærops* or *Lataenia*. The different species will succeed in moderately cool-houses; they are free growers, and may be exposed to the sun without damage. For table and room decoration they are exceedingly useful, especially *parviflora* and *radiata*. Not being fast growers, they last for years in a small state, and are therefore very suitable for small houses. The different species are:—

THRINAX EXCELSA (SYN., *TRITHRINAX ACULEATA*: JAMAICA).—This is sometimes called *Chamærops staurantha*.

T. *chuco* (West Indies), T. *gracilis* (Jamaica), T. *parviflora* (syn., *Sylvestris* et *elegansissima*: Jamaica), T. *pumila* (Jamaica), T. *radiata* (syn., *tunicata*: Cuba), T. *argentea* (Silver Thatch; syn., *elegans*: West Indies).

VERSCHAFELTIA SPLENDIDA (SEYCHELLES).—A grand palm, with foliage standing out flat from the stem, and when fully developed, three feet wide. The leaves are borne on slender stems, which are furnished with strong black spines, and they move gracefully with the slightest breeze. For a stove slightly shaded this is a fine plant; but care should be taken to keep it from cold air, which turns it yellow.

V. MELANOCHACTA (SYN., *ROSCHERIA*).—From the same island. It is a useful plant, though inferior to *V. splendida*.

VEITCHIA JOHANNIS (TROPICAL AUSTRALIA).—This somewhat resembles *Seafioria elegans*, but is more erect, and narrower in the foliage. As a vase or room plant, or for table decoration, it is very elegant—in fact, not to be surpassed. It also makes a good plant for mixing with Orchids; being slight in stature, it does not obstruct the light.

WALLICHA.—A genus of palms allied to *Caryota*, from which they differ in their fronds, being simply pinnate. They are free growers, though fond of heat and water; the undersides of the leaves are white. They will stand a considerable amount of ill usage; they are, therefore, useful for furnishing purposes. Otherwise, they cannot be said to stand in the first rank. The species are:—*W. caryotoides* (Chittagong), *W. densiflora* (Assam), *W. tremula* (Siam and Philippines). *Caryotoides* is the best.

WELFIA REGIA (TROPICAL AMERICA).—A good plant for stoves. Boing of a red tint, it contrasts with others; must have plenty of heat. In habit resembles an *Areca*.

ZALACCA.—The different species of this genus are allied to *Calamus*, from which they differ in being denser; they also grow to a larger size. For decorative purposes, much cannot be said in their favour, though, when young, the following are good kinds, especially as sub-aquatics:—

Z. EDULIS (JAVA).—Habit, spreading.

Z. WALLICHIANA (SYN., *WAGNERII*: INDIA).—Dense.

Z. CONFERTA (JAVA).—Frond, nearly round; green.

Z. AFFINIS (JAVA).—Near the above, but larger.

To palms, as to other popular plants, names have been given to which they had no kind of claim. In the foregoing enumeration, now brought to a close, these have been either omitted, or given as synonyms.

J. CROUCHER.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Brownia grandiceps.—This noble stove-plant is now in flower in the old orangery at Kew. In leaf or in flower, there are few subjects to surpass it; all large stoves should be embellished with its great globes of brilliant blossom. B. *coccinea*, which blooms more freely, but is not so fine a species as the preceding, is also now in blossom.—W. F.

Geranium v. Pelargonium.—Is a Pelargonium a Geranium? and, if not, how are they distinguished? [G. L.] A Pelargonium is not a Geranium through fructification; the Geraniums are easily distinguished from the Pelargoniums by their extreme hardness; whereas no Pelargonium that we know of is hardy, except P. *Endlicherianum*, and that is very rare, if in the country. All the bedding and show plants often referred to under this name are true Pelargoniums. The Geraniums may also be readily known by their regular flowers, and by having ten stamens, whereas Pelargoniums have irregular flowers, and usually seven stamens, and have moreover a peculiar feature in the arrangement of the stamens, so that the anthers are placed at the base of a sepal. There is, however, good excuse for the common mistake of confounding these plants, as at one time the genera we now call Erodium, Pelargonium, and Geranium, were all known to science by the last name.]

GARDEN DESTROYERS.

BARK-BORING INSECTS.

(*SCOLYTUS DESTRUCTOR.*)

THERE is one question regarding bark-boring insects which, however thoroughly examined and apparently finally settled, every now and then reappears, and offers itself afresh for discussion, according as new facts show themselves or old ones assume a new face; viz., whether these insects attack sound trees, or confine themselves to those which are moribund or in a bad state of health.

The question relates not only to our present subject, but to a great many other bark-boring insects; and it may be well, therefore, that in dealing with the first on our list, we once for all explain what we believe to be the true statement of facts regarding it. In the first place, we believe the fact to be that, while in general the trees which they attack are old or failing in health, there are also occasional instances where they are found attacking and more or less injuring trees which to all outward appearance are in perfect health. A few weeks ago, for example, a specimen of a small branch of an elm was shown at a meeting of the scientific committee of the Horticultural Society, which was found to have the bark literally crowded with the burrows and grubs of the Scolytus; and the branch was sound; perhaps a little dry, and as if not quite recently cut. We remember a similar instance occurring at Brussels a few years ago, where the efforts of the municipality to plant rows of elms in their new streets and boulevards were frustrated or greatly obstructed by the ravages of this insect; and, if we look nearer at home, in our parks, we shall not have much difficulty in detecting them in trees which, although perhaps past their best, are yet fresh and green. Notwithstanding these apparently opposed instances, and many others which could be cited to the same effect, we believe that it is only in failing trees that there is any reason to dread the attacks of the insects of which we speak; and this simply because if the Scolytus makes its attack on a healthy young plant which yields abundance of sap, the grubs are incommoded or drowned by its overflow into their burrows and around themselves. The dead and mummified remains of these insects, which may occasionally be found in their burrows, are the result of such an incident. It is only where there is such a lack of free-flowing sap that the grub can work away in a moderately dry medium that it can proceed with comfort to itself, or indeed can long proceed at all. This being the case we might expect that the parent insect will be endowed with an instinct to guide it to the selection of the tree suited for the abode of its progeny; and, in point of fact, it is guided to such a selection, but not by any remarkable faculty, or wonderful display of unreasoning instinct. Like a great many other instances of apparent design for which instinct gets credit, the wisdom in this case is simply the necessary result of the natural habits of the insect. The mother lays her eggs not on the exterior of the bark, but in the gallery which she herself makes in feeding under or in the bark, and if the bark be in an unsuitable state for her living and feeding in it, she goes away after trying it, or only remains (taking the chances of her condition) if she can find no other refuge. It is also to be observed that the perfect beetle may be able to stand and struggle through an overflow of sap, which might envelope and be fatal to small grubs.

In giving this explanation, we have assumed that it is only in trees where the sap is deficient that the Scolytus can live in comfort; but although we have only made the assumption to explain the principle, a moment's consideration of the manner of life of the insect will show that it cannot be otherwise. If we make due inquiry, we shall find that in every case to the contrary there is one of two things present—the trees attacked are themselves back-going and deficient in sap, which we imagine to have been the case in the example shown to the scientific committee of the Horticultural Society the other day; or there are special circumstances about the locality which provide an unusual quantity of the old beetles, accompanied with a scarcity of their special trees in a state fitted for them; they are thus

driven by the want of these to settle on the thriving young trees of the same kind, where they may survive for a short time until drowned by the sap; and if a constant fresh supply of old insects be from year to year provided to renew the attack, they may perhaps succeed in reducing the trees to a state of debility suited to their requirements, and then their progeny will run their course unmolested, and rapidly finish off the trees. This, we imagine, is what took place in Brussels. It is a city in which a large amount of wood is used for fuel, and large forests in the neighbourhood are grown for the purpose. There is thus constantly a large quantity of recently-felled wood around the city. This is brought in and stacked in its heart, bearing along with it myriads of bark-boring insects, which, by and bye, come out and search for trees suited for their purpose. The Scolytidae search for old elms, find none, and are driven to attack the young ones planted in the boulevards. As a matter of course, the trees there, having been transplanted when large, and breathing the air of a great city, are not in the most prosperous or vigorous condition, and are thus, although young, sufficiently feeble and languid in their circulation to be suited to their attacks. But even although they had been the most vigorous trees in the world, it would not seem extraordinary if, in time, they were to give way before the constantly renewed attacks of fresh hosts, annually brought in with the new supplies of firewood from without. We do not, however, know as a fact that this would be the case, for from an analogous case, cited by a great authority in such matters (M. Perris), it would appear to be doubtful whether that effect would really be produced. He states that in his district (the Landes) there are a good many industrial establishments which burn great quantities of logs of pine, and for that purpose make large stores of them. From these immense heaps of logs of all sizes there proceed innumerable swarms of Bostrichi, and above all of Hylurgus piniperda, and in the neighbourhood, quite near, occur some pine trees, either isolated or in groups of greater or less extent which nothing would seem to guarantee against their assaults; and yet M. Perris states that he never knew an instance of any one of these trees owing its death to them. They suffer more or less in their young shoots, which serve in the summer for refuge and nourishment to the Hylurgus, and notwithstanding the apparently very grave disturbance which these attacks, when much multiplied, cause to the economy of the trees, there still remains to them sufficient vigour and health to discourage more serious enterprises. The reason of their immunity he supposes to be that the Stone Pine (*P. pinaster*) is there in its own country, and that the climate and soil agree with it so completely that it is there able to resist morbid causes to which it elsewhere proves more vulnerable.

"On the other hand," says he, "I could show—for the traces still exist—pines, and more especially elms, attacked and riddled by ill-advised Bostrichi and Scolyt, born in the neighbourhood, and without doubt pressed to lay their eggs, and whose attempts have been defeated and projects disconcerted by the powerful sap. I have quite recently predicted a similar result to one of my friends who was in much alarm at the invasion by Scolyt of an avenue of young elms, which he was anxious to preserve, and which came from felled trunks lying not far off, and the event bore out my predictions, which I had based on the evident vigour of these trees." The practical conclusion to be drawn from these considerations is that where the trees are strong and vigorous we need not fear insects, and that if they are attacked, the best remedy is to supply it with nourishment, so as to improve its vigour and strengthen its constitution. A. M.

(To be continued.)

"War with Insects" (see p. 445).—This should have been called "War with Peach Trees." I can conceive nothing more injurious to a Peach tree than the application of wet paint, or even the proximity of wet paint; the very scent of the paint would inevitably kill the tree. As to aphides and "thousands of little snails being captured darting out," I would say with Tennyson of the departing year, "let them go;" but I can assure your correspondent, after noting aphides for fifty years, that they never dart;

they insert their trunks in the epidermis, and generally remain firmly fixed for life. At the end of the season, a last brood of aphides appears, and these have wings; but they never "dart." Each particular aphid opens his filmy wings, and waits for the breeze to take him off his legs, when he is borne, *nolens volens*, wherever the breeze likes to carry him. The motion is floating, not darting; like a little feather, he has no will of his own; he must go where the wind pleases. I will not contest the point about the snails; they may "dart in and out"; but from some little acquaintance with their habits, I think it unlikely. We entomologists are continually evincing a very strong desire to help the gardeners, but the gardeners invariably reject our services on the plea that we are not *practical men*; and I feel there is no help for it until an entire change comes over the spirit of the gardener—until he will consent to learn of the entomologist, and try to attain some knowledge of his insect enemies. Thanks to the late Mr. Walsh, to Dr. Park, and to Mr. Riley, this great work is progressing nobly in America; there a man who understands entomology is respected as a teacher, here he is condemned as a visionary; he who can train a Peach tree or a Pear tree to a particular pattern on a wall, is regarded as the only practical man. Believe me, some knowledge of insects is as needful as a knowledge of the use of the spade, or the hoe, or the pruning-knife; and until we can induce gardeners to acquire that little knowledge, they will handle the spade and the hoe and the pruning-knife in vain.—EDWARD NEWMAN.

THE ROYAL GARDENS, K.E.W.

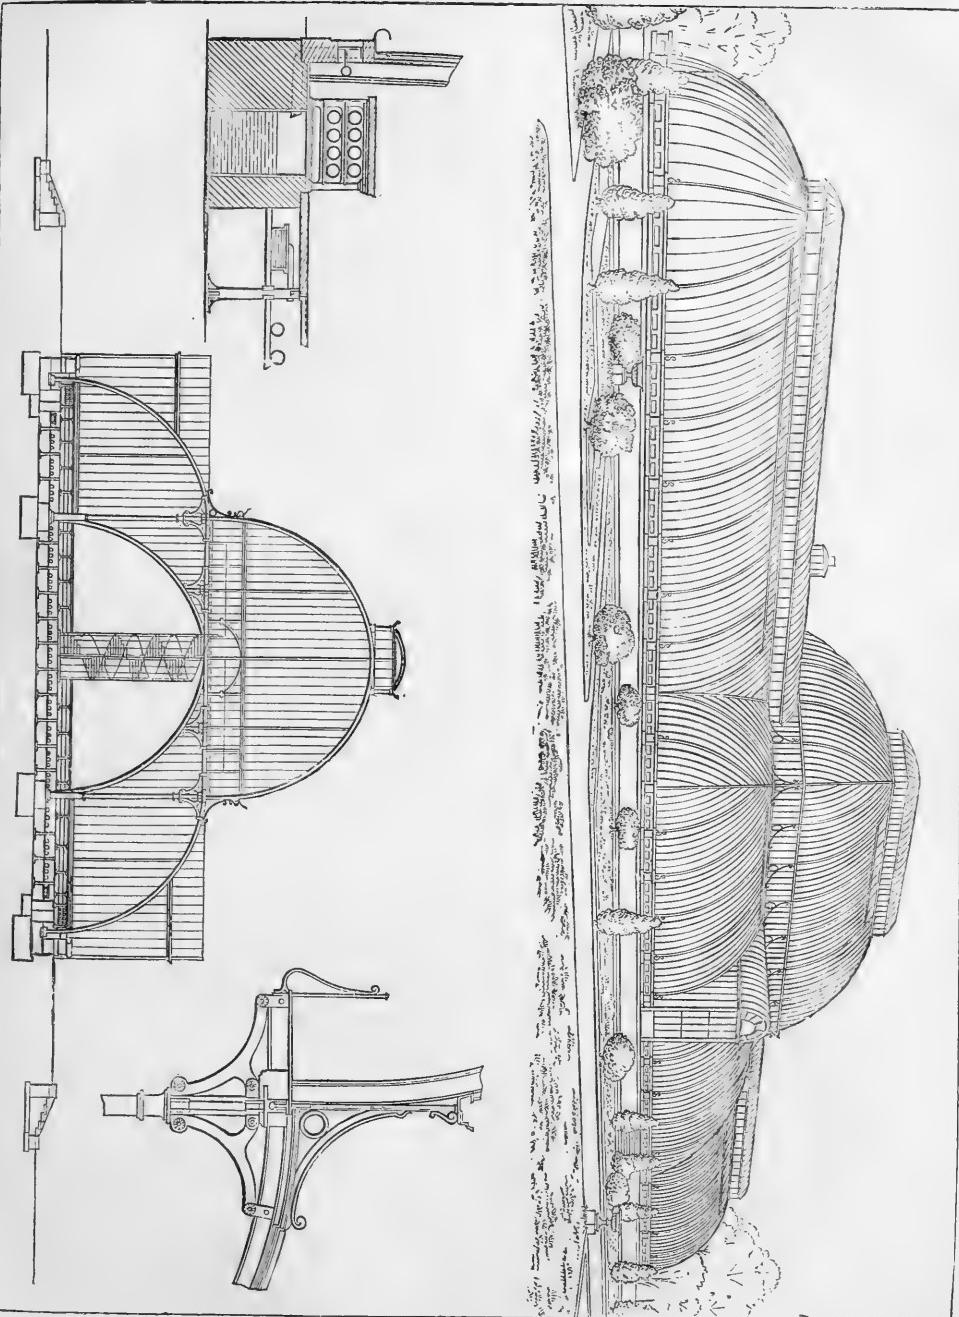

THE PALM HOUSE.

This noble structure still ranks amongst the finest erections of the kind that exist in any country. It was designed by Mr. Decimus Burton, and erected by Mr. Richard Turner, of Dublin, in 1849. It represents the first application, on a large scale, of malleable iron beams for the support of curved roofs, set on foundations of masonry. No timber whatever is used in its construction.

As regards general arrangements they can be easily understood by a glance at the annexed illustrations and at the ground-plan and sections which we published last week. The central portion consists of a square with two wings, each having semi-circular ends, the centre being raised above the rest of the building so as to afford accommodation for large plants. The roof is furnished with a continuous lanthorn, in which the sashes for ventilation open and shut simultaneously by means of machinery. This lanthorn is in keeping with the base and plinth, which is also provided with ventilators for the admission of air.

Round the central portion is a gallery which is reached by two cylindrical iron staircases, one for ascending and the other for descending, and from this gallery the whole of the magnificent palms and other tropical vegetation, with which the house is furnished, can be viewed with advantage. The exterior outline or contour is semi-ellipse, a form very suitable for a house of such large dimensions. The extreme length is about 362 feet, width of centre 100 feet, wings 50 feet, length of centre 137 feet, wing (each) 112 feet, height of centre 63 feet, wings 27 feet. It is set on a slightly elevated terrace, where it has remained without a single settlement or subsidence in any part, or almost the fracture of a pane of glass, since its erection. The glass and glazing were entrusted by Mr. Turner to Messrs. Chance, of Birmingham, the glass being of a peculiar tint of green, then thought to be most suitable for palms and other plants intended to be grown under it.

The interior arrangements are very simple. They consist of a wide side-shelf all round, with a series of ranges of hot-water pipes underneath it; the flooring, supported on piers of masonry, is of perforated cast-iron, under which is the main heating apparatus, consisting of hot-water pipes spread over the whole surface. No other material but iron could have answered the purposes for which this building is intended

VIEW AND SECTIONS OF THE GREAT PALM HOUSE AT KEW.

—for plants requiring great space, great heat, and great moisture. This building, in short, well illustrates the great superiority of curvilinear iron houses for all very large structures in gardens, its effect being very satisfactory from every point of view. We have seldom seen large conservatories of the opposite style pleasing in effect, and it is certainly a fallacy to suppose that they are better for plants. The great Temperate House at Kew is a noble structure, but there are few who would not prefer the older Palm House. It is difficult to say how any persons loving their country, not to say loving gardens, should erect such a structure as the new palm house in the Glasnevin Garden, with this in existence as an example. Of course, we do not expect every botanic garden to rival Kew with a palm house, but the principle may be applied on a smaller scale. There is only one style of palm house that we should think worthy of being named in connection with that at Kew, and that is such as the palm house at Edinburgh. In this case the sides of massive stone lend a more stately air to the structure than if the curvilinear ribs started from near the ground. Palms, as Mr. McNab has shown, thrive perfectly in such a structure.

We are indebted to Mr. H. M. Burton for the loan of some of the noble series of drawings, originally made by Mr. Decimus Burton for the larger structures at Kew, and from these the drawings for THE GARDEN have been made. We feel bound to state in conclusion that this and other houses built by Mr. Turner, of Dublin, do him great credit. We have now seen them in many gardens, private and public, and they always seemed to us, judged from an ornamental point of view, worthy to stand in the fairest garden, and always constructed with a view to the perfect health of the plants. The iron range at Glasnevin, the conservatory in the Regent's Park, and the range at Killakee are cases in point.

THE ARBORETUM.

THE PLANES.

BY GEORGE GORDON, A.L.S.

II.—THE ORIENTAL PLANE (*PLATANUS ORIENTALIS*—LINNÆUS).

This is one of the noblest trees of the East; it has wide-spreading branches and a massive trunk. Its peculiar character, however, is its being massive and graceful, yet open and varied in outline, with the lower branches extending horizontally to a considerable distance. Under favourable circumstances it attains a height of from sixty to seventy feet, with a trunk of large dimensions near the ground; but it soon divides into numerous huge spreading arms or branches, which, together with the stem, are covered with smooth, whitish-grey bark, that scales off every year in rather large, irregular patches, while the bark on the smaller branches and younger portions of the tree is more persistent, and of a brown colour, sometimes tinted with purple.

The *Platanus orientalis* is a native of Asia Minor, Persia, Greece, and Western India, where it extends as far as Cashmere. It is also found on the coast of Barbary, the south of Italy, and in Sicily; but most probably it is not indigenous to those countries. It is likewise found on Mount Etna, as high as two thousand feet above the level of the sea.

It is the "Chinar" of the Persians and the people of Western India, and the "Doob" of the Arabians. Griffith, in his "Notes on Western India," says the "Chinar" is common in Afghanistan at a place called Otiore, where it forms a large and handsome tree, but with a trunk never of any great height, and with the branches, when left to themselves, dependent, and of a great size. He also found the "Chinar" common in the province of Khorassan, at Ghuznee, in Cabul, Jalalabad, and Candahar. He states that a long avenue of it is a distinguishing feature in the city of Ispahan.

Dr. Walsh, in his "Residence at Constantinople," says that the great tree of Buylkde is an Oriental Plane of tremendous size, rising from the middle of a valley; it measures forty-seven yards in circumference at its base, and the branches afford shade to a circular area of 130 yards; he also assures us that there is no exaggeration in the statement, as he measured the tree himself in 1836. He says, however, that this vast stem divides into fourteen branches, some of which issue from

below the present surface of the soil, and some do not divide till they rise seven or eight feet above it. One of the largest has been hollowed out by fire, and affords a cabin to shelter a husbandman. This, if it can be considered a single tree, is certainly the largest of its kind in the world, and, as is conjectured by De Candolle, must be more than two thousand years old.

The leaves of this Plane are large, frequently measuring nine inches and a half in length, and eight inches in breadth; they are palmate, wedge-shaped, or tapering to the footstalk, and deeply divided into five pointed lobes or acute segments, the three outer of which are cuneate, and sometimes again slightly lobed, and all are furnished towards the points with acute indentations or large serratures on the margins; the petioles are rather long, and the principal veins palmately divided. The young leaves and shoots when they first appear in spring, are covered all over with a dense silky wool of a rusty brown colour, but which soon sheds, and, by the time the leaves are fully matured, totally disappears; the upper surface of the leaves becomes quite glabrous and of a shining green colour, while underneath they are much paler, and slightly tomentose in the angles of the veins and on the principal ribs; the stipules are entire, and the petioles so swelled

Leaf of the Oriental Plane.—Natural size, 2½ inches long, including footstalk, and 1¾ inches broad.

at the base as to cover the buds; the flowers are small and in close balls or heads, which appear before the leaves in spring, and the seeds in fine seasons ripen late in autumn, but the balls which contain them mostly hang on the tree until the following spring; the balls or seed-heads of this Plane are thickly furnished externally with stiff, bristly points, and elevated conical-shaped nipples, covered with a silky down, and vary very much in size, some of the balls being one inch and a half in diameter, while others are not more than three-fourths of an inch. They are produced on long, zig-zag, pendulous peduncles, sometimes six inches in length, and bearing from three to six balls or heads on each, generally crowded together, or but at short distances apart.

The Oriental Plane was first introduced into England about the middle of the sixteenth century, and some of the oldest and finest trees of it, near London, are at Mount Grove, Hampstead; in 1838 these had attained a height of from seventy to eighty feet, with massive trunks. It has the following synonyms, viz., *Platanus cashmeriana*, *nepalensis*, and *indica*.

BRITISH COLUMBIAN CONIFERS.

(Continued from page 503.)

JEFFREY'S DECIDUOUS TREES, SHRUBS, AND HERBACEOUS PLANTS.

BESIDES conifers, Jeffrey also introduced many deciduous trees, shrubs, and herbaceous plants. Many sent home by him had been introduced, while others were known only by name, but had not been previously sent home. One of the latter is *Nuttallia cerasiformis*, a shrub belonging to the Rose tribe. This plant ranks amongst the earliest leafing shrubs now cultivated in the open garden. The flowers are in racemes not unlike the white variety of the *Ribes sanguineum*. Although the *Nuttallia* flowers freely in the open border, it is wonderfully improved in appearance when grown against a wall. Among the numerous herbaceous plants sent home, those really new which have come under my observation are the *Dodecatheon Jeffreyi* and *Pentstemon Jeffreyi*.

As Jeffrey's expedition to British Columbia turned out a prosperous undertaking, its promoters were induced to organize another expedition for the further exploration of these coniferous regions. After several preliminary meetings, it was ultimately arranged to send out another collector, and Mr. Robert Brown, an enthusiastic Scotch botanist, was selected to undertake this second expedition. He started in March 1863, and was absent for nearly four years. Of conifers (the collection of which was one of the chief objects of the mission), comparatively few, however, were received from him; but these I shall now enumerate.

Of the genus *Pinus*, seeds of the true *P. Murrayana* of Jeffrey came up freely, being readily distinguished by the green colour of the leaves and beautiful upright habit of growth. Of the genus *Picea*, one kind only came up, named *P. grandis*. This plant is evidently one of the forms previously introduced as *P. lasiocarpa*, certainly not the true *P. grandis* of Douglas.

ABIES.

Of this genus seeds of several kinds were received, and two sent home as new were provisionally named—one, *Abies Parryana*, and the other, *A. Hanburyana*. The former has turned out to be identical with the *Abies Pattontiana* first introduced by Jeffrey, while the *A. Hanburyana* seems to be nearly allied. Its leaves, however, are longer, broader, and somewhat undulated. Some seeds of *Abies Douglasii* were sent home by Mr. Brown. They soon grew, but have a light-green colour, and much covered with resinous blisters in the young state, like those raised from Jeffrey's importations, having a habit almost identical with the early plants raised from British ripened seed, certainly very different in colour from those sent home by Drummond during the Franklin expedition, or by the ill-fated David Douglas during 1826. I feel convinced that there is a variety of the *A. Douglasii* yet to be sent from the Rocky Mountain district, infinitely superior to the generality of *A. Douglasii* seedlings received during recent years, having dark evergreen leaves, perfectly hardy, very upright in growth, and admirably adapted for forest purposes. Those sent home by Drummond are of this character. Some plants sent out by nurserymen under the name of *A. Douglasii taxifolia* may be this variety, but certainly not all, as some varieties cultivated under this name are rather tender, and have more or less a drooping habit.

SEED COLLECTING.

There is a circumstance to which seed collectors pay very little attention, but which calls for careful observation. Seeds are not unfrequently procured from medium-sized trees growing along the outskirts of pine forests. In such situations it is often impossible to depend on the progeny. The pollen of most coniferous trees is produced in very large quantities, and is often blown about to a considerable distance. To this cause I attribute the sickly condition of the plants raised from much of our home-ripened seeds, as is observable in *Abies Menziesii*, *A. Douglasii*, *Picea nobilis*, *Pinus monticola*, *P. Laricio*, and others. Such examples prove the necessity of foreign seed-collectors penetrating the pine forests in order to secure seeds in a pure and perfect state. The rarer species of conifers now cultivated in this country are not yet to be had in such quantities as to be grown in a forest condition. The chances, therefore, of impure seed are very great.

EARLY CONING.

A circumstance connected with the early coning of certain recently introduced conifers into this country deserves investigation. On inquiry, it will be found that early coning may be attributed to several causes. For many years the newer conifers were generally grown in pots perhaps for a much longer time than they ought to have been, and when planted out the roots were often matted together, rendering it often impossible to extricate them without injuring the plants. Such specimens were generally

planted with their balls of adherent earth entire. For several years these trees get on well, but in time sicken from a strangulation of their roots, which results in early coning. Another mode of bringing young trees into a coning condition, is the tying the stems upright which happen to be leaning to one side, from wind or other causes. The tying which some of these plants are often subjected to, and the after neglect of taking off ligatures used, has a tendency to cut into the bark on one side, and often weakens the top, which results in early coning. Another cause is from transplanting, and is particularly noticeable in plants of the *Pinus nobilis*. Although transplanting is often done for this express purpose, I have my doubts if the progeny of such trees can be relied on for producing permanent healthy plants. I am inclined to think that all these premature methods of inducing cones will produce a sickly progeny. It will be a service if those who have had experience in seedlings thus produced will kindly give the results of their experience; it would confer a favour on many cultivators, by saving the extensive planting of trees that will not ultimately succeed. The sickly state of many of our young larch plantations, I much fear, is owing to carelessness in seed collecting.

THUJAS.

Of this genus a considerable quantity of seeds was sent home by Mr. Brown, under the name of *Thuja Craigiana*. These have the appearance of *T. gigantea* sent home by Jeffrey, or the varieties sent by other collectors under the names of *T. Lobbi* and *T. Menziesii*. The varieties of *Thuja* received at different times from British Columbia are numerous, and from the slight difference observable in them, I am inclined to think that the seeds must have been collected from trees growing on different soils and situations.

JUNIPERUS.

Of this genus several interesting species are to be seen amongst the dried specimens received from Mr. Brown. Several packets of *Juniperus* seed were also sent home. The only one named by him was *J. Henryana*, of which two distinct varieties have come up, and are now in cultivation. As the true plant has not been described, it is difficult to know which was originally intended to bear that name.

DECIDUOUS TREES AND SHRUBS.

Seeds of these were also distributed; of the former, *Prunus Pattontiana* appears to be distinct, although more of a shrub than of tree growth. *Mahonia Balfouriana* seems to be identical with *Mahonia Aquifolium*, introduced from California in 1824. A species sent without a name has turned out to be *Spiraea alrixifolia*.

THE BUNCH AND OTHER GRASSES.

Perhaps one of the most useful introductions by Mr. Brown was the *Bunch grass* (*Elymus condensatus*). This grass is, without exception, one of the earliest we have in Britain, the leaves can be cut about twenty-four inches long at the beginning of March, while this year it was nearly thirty inches, and before the end of September the plants measure from eight to nine feet in height. Although introduced during 1864, it does not appear to be receiving that attention which I think it justly deserves. This grass should be thoroughly analyzed by competent parties, and its merits given to the public. It seeds abundantly in this country, and if found to possess sufficient nutritive qualities it could be readily increased. Seeds of several pasture grasses were also received and grew freely, but I have not heard of any good that has resulted from them. Besides grasses, seeds of many herbaceous plants were also distributed.

ENCOURAGEMENT FOR FURTHER EXPLORATION.

Mr. Brown's mission ended in the autumn of 1866. Looking through the dried specimens sent home by Jeffrey and Brown, as well as the introductions of Douglas, there appears yet to be ample scope in North West America for a collector to go over the same ground again. The original habitats of *Picea amabilis* and *P. grandis* of Douglas do not appear to have been touched upon by any other party, as no true seeds of these two species have again been procured. The *Pinus Balfouriana* and the true *P. flexilis* have only been sent home by Jeffrey; and the *Abies Hanburyana* and *Juniperus Henryana* only by Brown. Judging from the dried specimens received from the various collectors, interesting specimens of *Pinus*, *Picea*, *Abies*, *Thuja*, and *Juniperus*, have yet to be introduced. In these extensive and comparatively unexplored regions, a variety of soils and situations must be met with particularly adapted for certain species of conifers. Suitable spots, as damp, dry, loamy, or peaty, favourable to the growth of certain plants, are frequently very limited in extent. A collector may therefore pass within a few hundred yards of some rare species and never see them. From these regions a vast amount of novelties have yet to be procured, and such as would reward any young and enterprising collector.

JAMES McNAB.

THE GARDENS OF ENGLAND.

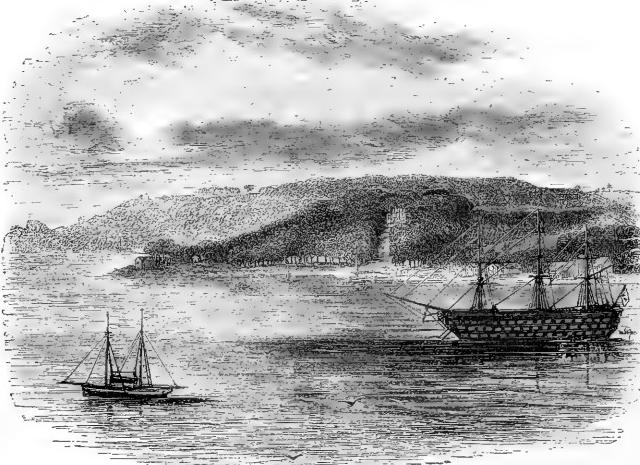

MOUNT EDGCUMBE.

This is a noble and extensive place, surrounded by a finely undulated park, stocked with deer and furnished with fine trees, consisting of Oak, Beech, Elm, and Chestnut. It also contains some very large evergreen Oaks, Cedars of Lebanon (which, for spread of branches or size generally, one seldom sees elsewhere), Thorns of select and beautiful kinds, and other ornamental trees. From the higher lying ground the views, both of sea and land, are marvellously fine, embracing, as they do, the town of Plymouth, with its bay, shipping, and dockyard, Drake's Island, and extensive inland tracts of the lovely counties of Devon and Cornwall. In short, few places are so charmingly situated as Mount Edgcumbe, from which can be seen Dartmoor, with its wonderful rocks and tors, as well as Lord Morley's park and domain, and other gentlemen's seats.

The wide and diversified prospects that rise on every side, of towering hill, flowery vale, furzy down, and fertile field, are such as cannot fail to awaken the most pleasing sensations. The peninsula occupied by Mount Edgcumbe stretches out its majestic heights, crowned by the noblest woods, into the ocean, where the waves break over reefs of black rock that lie at the base of the cragged cliffs. This beautiful domain is one of the most noticeable features in the landscape of Plymouth Sound. It may be viewed to perfection from the commanding eminence opposite Mount Wise. Here the whole of the expanse of its magnificent scenery, as well as the neighbouring landscape, is spread out unbroken to the view, and may be taken in at one comprehensive glance. Its appearance from the Plymouth Hoe is also particularly fine. The noble woods, rising tier above tier, with here and there patches of bright green, the blue sky beyond, and the deep tints of the water around, dotted with vessels, all combine to form a very pleasing picture.

At the entrance to the park is a splendid avenue of gigantic trees. These extend in unbroken order nearly up to the house itself, which occupies a commanding position. The trees are so arranged as to form three avenues—one very wide central promenade with side aisles. To our left we catch pretty glimpses of the sea, through the openings in the trees, which are here tastefully arranged. To the left of the house is a high walk, leading to the most beautiful part of the grounds, while further to the left is a lower path, which passes in many places close to the sea.

What is called "Lady Emma's Cottage" is a pleasant resting-place, situated at the foot of a wood, a "most delightful solitude of venerable trees," which tower up to a great height rendering the neighbourhood of the cottage shady and enjoyable. There is, too, a pretty little garden in front of this cottage, offering pleasing contrast to the overhanging woods. In due course we arrive at an upper walk, called the Great Terrace, or Laurel Walk, and proceed along through a dense

Mount Edgcumbe from the Sea.

plantation of fir and other trees towards Picklecombe, our path being at a considerable elevation from the sea, which lies far below us. The Valley of Picklecombe has, at its upper extremity, a building intended to represent a ruined chapel, from which the prospect is strikingly pretty, the little valley sloping away gradually towards the sea. On the further side of this valley is one of the most delightful parts of this charming domain. A portion of the Great Terrace continues in this direction, the road winding along among the most delightful variations of foliage, arranged in the most perfect order, and with true artistic taste. Here we find the Portugal Laurel, the Laurustinus, the Arbutus, and other evergreens and flowering shrubs, covering the whole surface of the cliff on either side; while on our left, as we proceed, we are attracted to various openings in the shrubbery, through which we catch tiny glimpses of the sea dotted with sails, while even and anon our ears are pleasantly assailed by the murmur of the waves as they beat in regular cadence some hundreds of feet below. This walk retains the same charming appearance throughout the year, the woodlands being almost entirely composed of evergreens. One Laurel tree has reached the astonishing altitude of fifty feet, and is supposed to be the largest of its kind in Europe.

The mansion itself boasts of considerable antiquity, having been erected in 1550 by Sir Richard Edgcumbe. It is in the castellated style, battlemented, and had originally circular towers at each angle, but during the latter part of the last century these towers were converted into an octagonal form.

The gardens, which are very extensive, possess some fine terraces, from which are obtained the most delightful views imaginable in every direction. The rosary itself is worth travelling a great many miles to see;

and the flower gardens are both extensive and varied. The English flower garden, as it is called, is of considerable extent, and is embellished with some very fine trees, among which may be noticed a grand old Cedar, one of the largest in England, which has so outgrown its space as to render it necessary for some of the boughs to be lopped off, while others are chained up. On a seat beneath this tree are inscribed some appropriate lines from Cowper's "Task." Another large Cedar measures twenty-one feet in circumference at six feet from the ground, and its branches spread ninety-five feet in diameter. There are besides some Cork trees, and fine specimens of the brave old English Oak. What is called the French flower garden is a small square enclosure bounded by a high hedge, cut close, of various evergreens. The garden is laid out as a *parterre*, with a basin and *jet d'eau* in the midst issuing from rockwork intermixed with shells, and surrounded by trellis work, on which numerous creepers are trained. In the Italian garden is a lofty orangery, one hundred feet in length, having a Doric front, designed by Lord Chelmsford. Into this building the orange trees, which include many fine specimens, are removed during the winter months, but in summer they are tastefully arranged in long avenues in the garden. This garden is encircled by a fine bank of flowering shrubs and evergreens, in the centre of which

is placed a basin of water, with a superb marble fountain. In the shrubberies, one of the most striking features belonging to the place, are some magnificent examples of Arbutus and common and Portugal Laurels, of a height and size equal to those of some timber trees; other evergreens, too, acquire proportionate dimensions. The Bamboos here are unequalled for beauty and elegance; and the scarlet Indian Tree and other Rhododendrons grow with surprising luxuriance; as do also Camellias, Myrtles, Chinese Azaleas, and Heaths. Indeed, plants which need the protection of glass in other parts of England succeed perfectly out of doors in this favoured climate, and acquire wonderful luxuriance. A lovely Malvaceous plant (*Abutilon vitifolium*) grows here to the size of a tree, which, for months together, is loaded with beautiful mauve-coloured flowers, each as large as a crown piece, making a glorious display. The foliage is handsome and vine-like. Mount Edgcumbe is also celebrated for its Magnolias, of which it contains many varieties—large and grand examples of that fine genus. Conifers, too, such as Sequoias (*Wellingtonia*), Araucarias, Pinuses, Abies, Junipers, Cypresses, Cryptomerias, and others, may also be found here as large and fine as in any other county in England. Especially are there beautiful groves of Pinasters, which here acquire large sizes. JAS. BARNES.

THE SIX OF SPADES.

CHAPTER XIII.

The President's Lecture—(concluded).

You have seen a well-bred hunter turned out for his summer's run, when the soft showers of April have made the grasses green, and ere the suns of May, opening the Buttercups, have converted every pasture into a Field of the Cloth of Gold. For half-a-dozen seconds, when the groom has quietly slipped over his nose the old "exercising bridle,"

which he knows so well, he stands gazing in amazement and perplexity, astonished as the rustic who, having formed his idea of cities from the occasional contemplation of a small market town in the distance, sees for the first time from some commanding height great London spread out before him. Hardly, at first, can he (I am referring now to the nobler animal of the two, the horse)—hardly at first can he realise his freedom; it seems to him too good to be true; but suddenly he apprehends the happiness of his state, and with a wild whimsy of delight he is away at speed, kicking as he goes, and giving ample demonstration to eye and ear that he thoroughly appreciates his new liberty. By and bye he may descend to a majestic trot, coming towards you with head erect, lithe, supple, elastic, "scarcely touching the ground, he's so proud and elate," and exhibiting a dignity and grace and power, which you can see in no other animal, and only in him when thus unusually excited. After a while, perhaps, he may treat eye and nostril to a sight and scent of the young, tender herbage; but he is much too happy to eat. Were he less so, he would hesitate where to begin, like the schoolboy, whom you treat at the confectioner's, and bid, in Lear's words, "take all." But now he has youth's gladness without its appetite, and he is racing off again, head down and heels in the air, as though about to rehearse

Mount Edgcumbe.

a series of somersaults for the edification of some favoured hippodrome.

A like joyous consternation, a like embarrassment of happiness are mine, my friends, when, released from the introductory part of my lecture, from my allegorical snaffle, I find myself free to expatiate upon a field—of roses, turned out as it were into the "rosea rura Velini," into those rose fields near Ghaze-poor, which the great Bishop Heber tells us extended over many hundred acres, or into that "beautiful plain covered with innumerable roses," of which we read in the more recent "Wanderings of an Artist." So let me have a metaphorical gallop to relieve my exuberance of delight; or rather, since the rosarium is not good galloping ground, let me, like some nightingale just arrived in a rose nursery, and who can "scarce get out his notes for joy," take a preliminary fly over the premises, with obligato and irregular music, ere I settle down to sing in a more measured time and in a more usual key.

Hurrah, then, for the royal Rose! for a Queen who, like our own Victoria, reigns the wide world over in loving hearts. Hurrah for old England's emblem, emblem true of a happy land, whose sons flush quickly with a righteous anger to resent injustice and to defend the right, and whose daughters blush

with a rosate beauty, with the "shame, which is a glory and a grace."

Hurrah for the precious perfumed flower, which, for seven months of our fickle and inclement year, gives its welcome beauty to high and low, admired and loved by us all, from the patrician, who sees it in the golden epergne of the banquet, to the ploughboy, who sticks it in his coat o' Sundays, and seemst to his younger brother, learning his Collect, the embodiment of earthly bliss, as to a junior at Eton his gorgeous fraternity in the Life Guards. Hurrah for the flower, which in all history, sacred and

secular, maintains priority of praise; which the Greeks named to *anthos*—the flower, and of which all their poets, heroic, pastoral, sentimental, comic—Homer, Theocritus, Aristophanes, and "burning Sappho," sang; which the Romans strewed before their victorious chiefs, chose first to ornament their homes and feasts, and even offered to their gods; which all nations, emancipated from barbarism, have ever fondly cherished; which displays its charms, as our English girls their loveliness, with an infinite variety of form, grace, and complexion, now *petite* as some pocket Venus (anglicé, "a little duck") and now beautiful abundantly—

"A daughter of the gods, divinely fair,
And most divinely tall!"

(colloquially, "a glorious girl, sir"); which, only requiring in ordinary gardens the smallest share of attention to insure an ample bloom, may be induced by a patient and careful love to reveal its glories under adverse skies—which finally, my Mattocks, is the Queen of flowers, *Rosa Mundi*, perfect, peerless! "True," says the French proverb, "*true aime mieux bran que Roses*"—the sow would rather have its nose in the swill-tub than smelling the sweetest posy; and he is a hog who does not love the Rose.

There! The hunter has had his gallop round the "rosea

rura," the nightingale alights breathless in his bower of roses; and we will moderate our pace now, if you please, and pitch our note an octave lower.

But we follow, though more slowly, the same route; the refrain of our song may not be changed, *Rose est Bonheur*, the Rose is happiness!

To review them more calmly and to demonstrate more practically what I have said, I will speak first of the Rose's popularity. In March 1860 I received an application from a society of working men at Nottingham, inviting me to assist at their "Rose Show," which they proposed to hold on Easter Monday. As I had not at that time a Rose-bud in my possession, and never entertained the idea of an artisan with a conservatory, I came to the conclusion that some facetious friend was enlivening himself at my expense, and I wrote back curtly, inquiring what particular roses were so kind as to bloom at Nottingham three months before they condescended to appear in other less favoured localities. The reply, that the flowers intended for exhibition were grown under glass in pots, made me thoroughly ashamed of my incredulity; and on Easter Monday, 9th April, I set forth in a snow-storm, not daring to reveal my mission to anyone—for who was likely to believe me?

and travelled forty miles in all by rail and road for the show. Never was journey more delightfully compensated. Driving through sleet and sludge to the "General Cathcart," the weather pain-fully recalling that hero on the hills of the Crimea, I found, to my sudden but complete happiness, a long table covered with roses! Yes, there were our summer sweethearts, fresh and fair, smiling at the hail which pattered against the windows, as though reproofing them for their precocious forwardness. Ah, did we not enjoy our stolen kisses, the bright glowing tints,

shining foliage, the delicious perfume! Had we not a genial, joyous time of it, praising and comparing our charmers, and, rose-growers all of us, saying our say without reserve or restraint? Then, after an hour's thorough enjoyment, I went, with the most successful trainer of the day, a bricklayer, and a very pleasant companion I found him, from the race-course to the stables—from the show to the greenhouses, some of them so small that I, being of extra size, and wearing a winter overcoat, was compelled to remain outside, and all of them belonging to working men, who, living in the town, often come long distances, before and after a hard day's labour, to attend to firing and watering, and to wait with an affection, which defies all difficulties, upon their lovely mistress, the Rose. I went home with my heart full of pleasant thoughts, and with my hands full of such winsome flowers as made every passenger in the train livid with envy.

Passing over a thousand intermediate examples, and skipping to the top of the social staircase, let us again suppose ourselves, three months later in the season, at the third national Rose Show in the Crystal Palace. Do you see a lady in mourning, elbowed by the unscrupulous, anxious crowd, but making her way good-humouredly as best she can, evidently charmed with the spectacle, and taking notes with all the

enthusiasm of an amateur? It is the Duchess of Sutherland, it is the Mistress of the Robes, waiting upon the only Queen in all the world more beautifully robed than her own. She bends in fond allegiance, but not more loyally, not more tenderly, not more heartily than those earnest men, who work for their bread at Nottingham.

For duration, in the next place, what flower dare, upraise her head to dispute the supremacy of the rose? "Gather ye roses, while ye may," says old Herrick, and with us rose-growers is it not almost "always May?" From that month to December, at all events, from the first blooms of the charming Banksiae and of Gloire de Dijon on our warm south walls, until the last Giant of Battles must yield to Jack (the Giant-killer) Frost, we subjects of Queen Rosa may wear in our button-holes "of loyalty this token true." Whatsoever the weather in the intermediate months, however "deformed by sullen rains," or by continuous drought, a rose tree, in good health to begin with, will have its bloom sooner or later; and, because different seasons suit different sorts, some trees in the Rosarium will ever assume for our delectation their most perfect phase of beauty.

Consider, too, not only their diversity of colour—and if you wish for special examples of this compare Maréchal Niel with Pierre Notting, or the Baroness Rothschild with Xavier Olivo—but also their diversity of form. You may grow the Rose in a thumb pot, with a flower "in shape no bigger than an agate-stone on the fore-finger of an alderman," or you may cover the front of your house with it. You may, in fact, grow the Roses you most like in the form you most like—standards or half-standards, pillars, pyramids, or dwarfs. And I may say here, that I prefer to grow my own roses, generally

speaking, on briars about two feet above the ground, for thus they require no unsightly props, no rain can spoil their blooms by beating them against the wet earth as with dwarfs—their complete beauty is brought off once before the eye, and, being within easy manipulation of the gardener, a symmetrical proportion is more readily attained, and of course more lastingly prolonged. Tall standards are very useful for the back row in borders, or as the centre of beds, but are rarely beautiful in an isolated state. Their most zealous admirers must allow, I think, that the more the briar is concealed the more attractive is the tree—that the more we see of the banner, and the less we see of its pole the better; and no opponent of the Standard, though he liked it as little as the Scotch our Standard at Northallerton, could require a more full confession.

Then, as to cost, you may establish a rose garden with the money which is asked for a rare Pinus or Orchid, and may reproduce your favourite varieties on the hedgerow briar or the Manetti stock, by the easy, interesting, and sure processes of budding or grafting, at a very small outlay, and to almost any extent. But be cautious, my Spades, unless you have a taste for rubbish, not to order your rose trees, nor your anything else, from those cheap jacks of the floral market, who profess to be so much more liberal than their neighbours

Mount Edgcumbe.—View in the Gardens.

Buy good razors, Oh, my friends, as ye love to enjoy your breakfasts with a temper smooth as your chin; and buy good rose trees, Oh, ye amateurs, as ye hope to look gladly on your feast of roses, when "the time of roses" shall come. The prices charged by the best growers are quite low enough (and you will believe one who has bought and buys largely) to insure a good article to the purchaser and a fair remuneration to the seller.

For ornamental purposes, as a cut flower, what have we so effective as the Rose—whether in the bouquet of some ball-room belle, herself—

"A Rosebud set with little wilful thorns,
And sweet as English air can make her,"

in the elegant vases of the drawing-room, or, as I most rejoice to see them, in the cups of silver, won by their ancestors, upon the dinner-table and with the dessert? When Horace invites the friends of Plotius Numida to celebrate with appropriate honours the return of that distinguished officer from Spain, he bids them to have abundance of Roses at their feast ("neu dosint epulis rosa"); and when he essays to cheer up Sam, in the person of Q. Delliis, he recommends him to lose no time in giving an order for Roses ("flores amanos ferre jube rosa"). Without endorsing his other recipes for driving dull care away, I may sympathise with him, I hope, in his love of the Rose; and I like to fancy him, calling upon his friends to pass the Falernian, and, having previously proposed to them his favourite toast, "pulchra puella, novies honorata" ("the Ladies, with three times three"), requesting them to drink without heeltaps (the Latinity for heeltaps is lost) "Vivat Regina Florum" ("Long Bloom the Rose!").

I leave you, dear brothers, in their sweet society. Tend them with all love and care; and then, as surely as from the rose trees of sunnier France comes the glory of our English gardens, you shall rejoice to repeat from a thankful heart,—

S. R. H.

(To be continued.)

THE GARDEN IN THE HOUSE.

BULLETINS OF A FLORAL CELEBRITY.

BEING A REPORT OF THE DAILY STATE OF MARÉCHAL NIEL, FROM AMPUTATION TO THE CLOSE OF THE SIXTH DAY AFTERWARDS.

EVERY lover of roses must feel an interest in the length of time which a cut bloom will endure in its beauty after amputation from the parent plant. Some kinds seem to possess much more vital power than others, and will preserve their freshness longer. Others, again, are so evanescent in their character, that, like the American convolvulus—the Morning Glory—they lose the freshness of their beauty before the first mid-day sun has glowed upon them after their expansion.

Maréchal Niel at the first glance, like Devoniens, and others of its class, might be deemed a flower destined to a very brief existence. The long flake-like petals seem to hang as by a breath—

"So slight, so faint, the slightest gale
Might whirl the leaves on high."

like the petals of the flower on Zuleika's tomb of which Byron sings; but the apparent slightness of the hold of those gracefully drooping petals on the rim of their calyx is one of seeming only, for they are on the contrary very stoutly set in round the strong margin of their cup of life, and revel in their beauty and gradual expansion during many days.

Thursday, April 13, 1872.—The specimen under description was gathered on this day in a conservatory near Southwell, Notts, from a plant which covered the entire roof, and which was thickly furnished all over with the noble blooms of this truly glorious rose. After amputation, it was carefully deposited in a paper bag, and supported on all sides with cotton wadding, in which state it was put into a safe place in a portmanteau, with the idea that it would reach London by that evening's express.

Saturday, April 20, 1872.—It was, however, mid-day on Saturday before the closely-packed prisoner was taken from his cell, looking none the better for his close quarters. The stalk was then nipped shorter, and placed in tepid water; but the ill-used flower drooped disconsolately over the rim of the glass. The noble foliage (leaves nearly four inches long) persistently flagged, as though making up its mind that such rough usage ought to be resented, and that a refusal to recover should be steadily persevered in. Towards evening, however, there was more freshness in the foliage, and the beautiful flower itself slightly revived, assuming

more firmness, and exhibiting a slight disposition to disclose the beauties of the inner petals to view and display the lovely tones of their deep orange-yellow, rich and glowing as the hue of ardent flame; but still the bloom hung languidly down, and refused to be entirely comforted.

Sunday, April 21, 1872.—The freshness of the night, and perhaps dreams of dew, though there was none, to fall, produced a surprising revival; and this morning, the Marechal, after having his stalk cropp'd again, and the great weighty flower supported by an invisible wire-guard, so as not to be dragged down by its own weight, came out literally on *grande toilette*, in "Sunday best," a truly gorgeous flower, and was greatly admired and praised as a wonder of floral beauty by all who came to pay their respects. It may be truly said that as the Marechal lolled in conscious magnificence over the side of the small glass vase, that the most extravagant amount of praise could not have been deemed flattery; and yet the flower was still but a bud—only as yet a half expanded flower.

Monday, April 22, 1872.—After having again passed a cool and refreshing night the Marechal arose like a giant refreshed with sleep; and displaying more conspicuously than hitherto the crumpled, quilled, and plated petals of the deep golden depths of his central focus of beauty. The stately Marechal was now more than half expanded, and wore the splendour of his magnificence with downright audacity; as well he might.

Tuesday, April 23, 1872.—Continuously increasing vigour was again apparent. The expansion had become nearly complete, and the spectacle of a semi-sphere of golden beauty was revealed, which was the crowning glory of the breakfast-table; all that remained to be desired was that the "Autocrat," of that choicest and joyousest of meals were present to describe the spectacle in words of which, at that hour, he alone has the supreme command.

Wednesday, April 24, 1872.—The ultimate glory of full development was completed; rather, over completed, as certain omens of a coming change were revealed, just as the autumn trees disclose by the very splendour of their hues "the beginning of the end." But the grand flower was perhaps more beautiful than ever at that critical stage of its triumphant career.

Thursday, April 25, 1872.—The field marshal of the roses was still the glory of the breakfast-table, though some of the petals were somewhat too widely spread for symmetry—but—but—the heavy footfall of a late arrival at the breakfast-table brought on, somewhat suddenly, the impending change—the marshal gave up the imperial spirit of his floral reign, and his sheaf of glorious petals fell in a heavy shower upon the snowy cloth, making it veritably a field of the cloth of gold.

Friday, April 26, 1872.—The fallen petals having been sepulchrally collected and dried in the penetrating rays of the April sun, were affectionately deposited in that porcelain mausoleum of embalmed flower petals, vulgarly called the *pot pourri*; to which a new perfume was thus added, less luscious than that of the Provence rose, and more like that which Alexander Dumas calls the "*parfum acre de la mer*" shedding around a delicious freshness and ever-uncoying delight of fragrance.

NOEL HUMPHREYS.

STEPHANOTIS FOR CUTTING.

For purity, sweetness, consistence, and durability, orange-blossom is nothing in competition with Stephanotis. Seldom of the purest white (unless it be the double-flowering variety), and always liable to be scattered into fragments by the advancement of the ovary, orange blossoms have little but association to commend them as cut flowers. But the Stephanotis—who can describe the spotless purity and wax-like consistence of its clustering tubes? And the flowers are as durable as sweet, and seem made to fit into any niche or place where purity or fragrance is wanted. Bunches of Stephanotis, set in their own leaves, running round tresses of black hair, would add a fresh charm to the Queen of Beauty herself. As for flowers for button-holes, three tubes of Stephanotis, backed against a glossy leaf, are perfection on a black coat. A wedding bouquet is required; it could be formed of Stephanotis alone, interspersed with green leaves; but it would be better still were a white Camellia forthcoming for a centre, and then bunches of Stephanotis intermingled with spikes of Lily of the Valley, single flowers of pure white Azaleas, finishing with a few Calanthes. The bunches of Stephanotis as they grow are mostly too large for bouquets. Three or four tubes, with a sprig of green, are sufficient. They must be mounted on wire, and the base of each bunch of flowers should have a tiny cushion of damp moss to rest upon. So furnished, there is hardly any limit to the durability of these flowers. I have known them to keep fresh and sweet for three weeks or more after they were cut and made up.

The way to get a good supply of bloom is to plant several plants out, and let them ramble freely over the walls, ends, or roofs of plant-stoves. Although the plant blooms freely in pots, it is difficult to get sufficient flowers from the limited areas of pot plants. There is, too, another reason for planting out the Stephanotis and growing it loosely and almost untrained when practicable, and that is we are enabled in that way to cut branches of it of sufficient length for twining round the stems or handles, or hanging over the sides, of large vases and baskets. Those who have once used it thus will say that in no other way can its full merit for cutting be exhibited.

Useful as it is in bouquets—charmingly beautiful as I have seen flat arrangements of its flowers intermingled with *Myosotis diffissiflora* and fringed with the same so widely as only to show the tips of its glossy green leaves, yet to see the drooping branches laden with their burden of purity and sweetness, and the leaves glistening with artificial dewdrops on their glossy surface!—nothing can well equal it, unless it be the roof of the stove, where it will grow with a luxuriance and flower with a freedom that it seldom attains when grown in pots. Not but that the plant is admirably adapted for pot culture; and this mode of growing it possesses several advantages over any other. For instance, pot plants may be forced out of season, and the plants will bear conservatory treatment when in bloom, thus prolonging its season at both ends. Everyone who has a stove should grow *Stephanotis*, although, to have quantities of blossom, ample space and free growth are requisite. The plant will flower in a very small compass, and will bear a good deal of hard treatment. One of the most free-flowering plants I have ever known occupied the back wall of an early viney়. After the grapes were ripened, the autumn treatment of the house was not modified in any way for the *Stephanotis*. The house received the open-air treatment common to other early viney়—that is, it was exposed as much as usual without being actually unroofed, and this plant never missed flowering. Still I have never seen the plant do well in a conservatory. It was one of the aims of the late Mr. Donald Beaton to convert the *Stephanotis* into a conservatory climber. For this purpose he applied bottom heat to its roots in the fine conservatory at Shrubland for years, and succeeded in flowering it pretty well. But its proper place is the stove. Although it flowers on the current year's wood, yet it should be ripened well in the autumn, and kept tolerably dry during the winter. It then breaks with vigour, and flowers profusely. Though I have given a strong opinion in favour of using large branches of *Stephanotis* where available for decorative purposes, there are few flowers better suited for dinner-table decoration in accordance with the latest fashions than the *Stephanotis*, gathered simply in bunches, arranged in flat glass dishes or slips, and interspersed with tiny bits of scarlet flowers or berries—such as those of *Rivina humilis*, or with blue ones, and fringed with brightly shining green. Few flowers could look better lining, flanking, or encircling centre pieces, while none could be sweeter on the dinner-table than the *Stephanotis*.

F. D.

EUCHARIS AMAZONICA AND GRANDIFLORA.

UNLIKE many white flowers, the blossoms of these two useful plants are not easily tarnished; when cut they may be made to do duty as centres to bouquets two or three times, and their perfume is most pleasing. A few stems of the *Eucharis* springing from their own leaves is rich furnishing for a bridal breakfast-table. The effect may be heightened by using *Caladium* leaves in lieu of or mixed with those of the *Eucharis*. The flowers also look superb in larger arrangements combined with some of the higher-coloured Amaryllises. The *Belladonna Lily* is perfect in conjunction with the *Eucharis*. Some of the *Narcissi* also blend or contrast well with its large pure white flowers. In flatter arrangements, single flowers of the *Eucharis* are very effective. We partially fill flat dishes of glass with water, and float Begonia or *Caladium* leaves of different colours over their surface; on or among these the *Eucharis* blooms are dotted at regular or irregular intervals, and the effect is truly beautiful.

But the *Eucharis* is emphatically a flower for bouquets. Three blooms for the outside would raise any bouquet far above mediocrity. Combined with *Camellias*, either as centres or intermittent fringes, *Eucharis* flowers are magnificent. Leaves of the lovely *Caladium argyrates* form the best fringe for bouquets in which *Eucharis* flowers predominate. They fit in, harmonise with their character and form, and, if possible, lend fresh charms to their sweetness and beauty. It seems probable that the *Eucharis* will soon be considered as indispensable for bouquet work as Lily of the Valley, Violets, or *Stephanotis*, and that thousands of it will be grown for this purpose. Few plants can be easier cultivated than it is, and it has the merit of blooming many times in one year, if not perpetually.

D.

GRASSES FOR TABLE DECORATION.

WE shall soon be able to avail ourselves of the bloom-spikes and leaves of grasses for the ornamentation of vases, and doubtless I am not singular in entertaining pleasurable anticipations of the time when these graceful adjuncts to a bouquet are again at our command. When *Camellias* are over, Roses are nearly ready to take their place in our flower-vases; when the long summer reign of these is coming to a close, Dahlias and Asters are at our call for similar uses, and these

again are succeeded by Chrysanthemums, which carry us on until *Camellias* are ready for us again. But flower-spikes of grasses, which are coming in during May, are at their best all through June, and are getting scarce towards the end of July; what is there, therefore, that can fill their place at other seasons of the year? Literally nothing; let us, therefore, make the most of them while they last.

Grasses certainly have been more used during the last few years than previously for vases, i.e., if the competitions for table decorations at our flower shows may be taken as indicating the style of the period. At the same time I feel sure that they might be much more used than they have yet been. In the engraving which accompanies this, it will be seen that grasses predominate over all the other types of

Vase decorated with Grasses.

flowers and foliage; and the general effect can hardly be surpassed for grace and elegance.

The fashion of the day to value plants more for their rarity than for their intrinsic beauty, will, no doubt, account for the want of attention that has hitherto been paid to many wild plants of common occurrence suitable for decorative purposes. There are many foreign grasses of an exceedingly graceful character which might be grown in pots, and thus made available for conservatory uses as well as for bouquets and vases; and if some of our enterprising nurserymen would only advertise them at half-a-guinea a plant there might be some hopes of obtaining for grasses generally, and for our wild grasses in particular, a greater appreciation of their merits than is at present bestowed upon them.

W. T.

Violets in Moss.—Allow me to add another plant to the list of things mentioned by your correspondent "W. T." (p. 410) for the arrangement of Violets, namely, the moss *Hypnum splendens*. No wiring is needed, and the operator may place flowers or leaves just where he pleases; I could fill a large saucer in a quarter of an hour. I pull the moss into pieces, rejecting the lower part, which is brown; I then lay it lightly in the saucer, raising the middle, to give it a convex form, and put in my flowers and leaves as described by "W. T." If the moss is allowed to hang a little over the edge of the saucer, it gives a very elegant finish; but it has this objection, it conducts a quantity of water out of the saucer on to the table. This may be got over, by placing the saucer on a neat plate (say, of glass), with a few bits of moss in the space between.—T. SMITH, Teignmouth.

COVENT GARDEN MARKET.—May 10th.

Flowers.—Among flowers in pots, are different kinds of Polygalas; Eriostemons; Petunias, both single and double; Pelargoniums, double-flowered, fine-leaved, and others; also small Hydrangeas, with immense heads of bloom, in some instances blue, owing to their having been grown in peat or irony soils. In addition to these there are also Rhodanthes, Lobelias, Heliotropes, and different kinds of Cacti in flower; Heaths, Gardenias, Calceolarias, Fuchsias, Gloxinias, &c. Cut flowers consist of Roses in great variety, sprays of Orchids, Eucharis, Stephanotis, single and double Deutzias, Schizostylis, Ranunculus, Anemones, Bouvardias, Narcissi, Mignonette, Pinks, Peonies, and various fine-foliated plants.

and to *Pelargonium elegantissimum*, to *Iris iberica*, var. *Perryana*, to *Funkia japonica aurea*, to *E. Fortunii*, from Messrs. T. S. Ware, Tottenham; to *Pelargonium Lord Bacon*, and to *P. Guinevere* from Mr. Wm. Paul, Waltham Cross; to *Polystichum angulum proliferum*, *Henleyi*, to *P. angulare variegatum*, to *Hedera concolorata*, and to *Pelargonium Empress*, from Messrs. Ivory & Son, Dorking; to *Azalea Alphonse Lavallee*, from Messrs. H. Lane & Son, Berkhamsted; to *Cordyline longituberosa*, from Messrs. Carter & Co., High Holborn; to *Pelargonium Prince Charlie*, from Mr. Porter, Sion Lodge, Isleworth.

Prizes were awarded for *Herbaceous Stove Plants*, first to Mr. G. Wheeler, Regent's Park; for *Roses* in pots, first to Messrs. Paul & Son, Cheshunt; for *Calceolarias* first to Messrs. Dobson & Son, Isleworth; for *Azaleas* (nurserymen) first to Messrs. Lane & Son; for *Azaleas* (amateurs) first to Mr. Hill, gardener to H. Taylor, Esq., Avenue Road; second to Mr. Wheeler; for *Alpine and Bulbous Plants* first to Mr. T. S. Ware.

Miscellaneous prizes included one to a group of *Maples*, and a silver medal to a group of *Roses*, from Messrs. Veitch; a bronze medal to a group of *Roses* from Messrs. Paul & Son; a similar award to a collection of cut *Roses*, and a silver medal to a collection of *Pelargoniums* from Mr. Wm. Paul; a silver medal to a group of plants from Messrs. E. G. Henderson & Son; a silver medal to a collection of plants from Mr. B. S. Williams; a bronze medal to a collection of hardy variegated foliage plants; extra prizes to a stand of *Pansies*, a stand of *Pteryrhums*, and *Bedding Pansies* from Mr. T. S. Ware; a silver medal to twenty flowering plants, and a bronze medal to a collection of foliage plants from Mr. Wheeler; a similar award to a collection of plants from Mr. James; extra prizes to a collection of *Calceolarias*, and also to a stand of cut blooms from Messrs. Dobson & Son; and special certificates to a collection of *Tropaeolum Lobbi*; and a collection of cut blooms of hardy spring flowers from Mr. Porter.

DINNER-TABLE DECORATIONS BY GASLIGHT AT THE BIRMINGHAM HORTICULTURAL SHOW.

I wish to direct attention to this class of "exhibits" in the schedule of prizes in which it stands as follows:—

"Class 145, dinner-table decorations by gaslight. Dinner-table completely laid out for fourteen persons, and arranged so as to show the best means of utilising fruit and flowers in its adornment. The "exhibits" will be judged and exhibited by gaslights. Open. Prizes, £20, £15, £10, £7."

I find some misapprehension exists as to the time when these dinner-table displays will be exhibited, the words "by gaslight" having led some to suppose that they are to be seen in the evening only. This is erroneous. They will be exhibited in the daytime in a tent specially constructed so as to exclude daylight, and which will be lit with gas, the object being to show what plants and flowers are best adapted for decoration by artificial light, the light by means of which such decorations are usually seen in this country. The regulations for this class will be found on pp. 7, 8 of the schedule, copies of which I shall be happy to send on application. Much interest has been excited respecting this class, and I have no doubt that it will prove one of the most interesting in the exhibition. Entries close for it on Wednesday, the 28th instant.

EDWARD W. BADGER, Hon. Sec. (Local).
"Midland Counties Herald" Office, Birmingham.

Asphalte Paving.—The *Metropolitan* says that this paving appears to be becoming popular in the City, in spite of all the criticisms to which it has been subjected since its first introduction. As far as can be judged at present there is little to choose between the four kinds of asphalte which have been tested, or are to be tested, by the Corporation. The inhabitants of Bishopsgate Street, without have petitioned for the repavement of their roadway with asphalte, and the inhabitants of Walbrook have laid a similar memorial before the Commissioners of Sewers. Mr. Hora gave notice on Tuesday last at the Commission of Sewers that he would move at the next meeting that Houndsditch, which is now in a dangerous state, should also be paved with asphalte. The Streets Committee has further reported in favour of paving the carriage ways of Lothbury, Bishopsgate Street Within, Leadenhall Street, and Gracechurch Street with asphalte. In a short time, therefore, we may expect to see all the principal thoroughfares in the City paved in this way.

ANSWERS TO CORRESPONDENTS.*

G. P. (It is intended that *THE GARDEN* shall be bound up in half-yearly volumes, each of which will be furnished with a full and comprehensive index)—M. C. (Rough tarpaulin, nailed on light frames about eighteen inches wide, is the cheapest temporary covering for the dangerous months.)—P. I. N. (The Manetti stocks budded last summer should have been down early in March; it is late now, but still they had better be done at once.)—A. B., KELSO (Thanks)—R. M. (Burnt material, either clay or sand, acts only mechanically on soils with which it is incorporated.)—P. (The double-flowered variety of *Saxifraga granulata*).

* All questions likely to interest our readers generally are answered in the several various departments.

SOCIETIES, EXHIBITIONS, &c.

ROYAL BOTANIC SOCIETY, REGENT'S PARK.
(MAY 8TH.)

UNGENIAL weather had apparently its effect upon this, the last of the spring exhibitions this year, for it was scarcely so fully supported as might have been expected. There were, however, excellent collections of *Roses* in pots, bearing abundance of blooms of the finest quality. Besides those in pots, several stands of cut *Roses* were also present, large in size, and distinct in colour. Amongst Teas, *Marechal Niel* stood pre-eminent, accompanied by President, a pink flower of wonderful size. Associated with these were also *Souvenir d'un Ami*, Climbing Devoniensis, the well known *Gloire de Dijon*, and *Mme. Williamson*, with light yellow, very double flowers. Among Hybrid Perpetuals we noticed *Charles Lefebvre*, large, rich, velvety, crimson, Duke of Edinburgh, Victor Verdier, *Therese Levet*, *Centifolia rosa*, and others. *Azaleas*, the glory of May shows, were well flowered and extremely beautiful, especially half a dozen large plants trained pyramidally; another half-dozen smaller plants were also densely flowered, and trained so as to completely hide their pots. Other specimens were poorly represented, except a little plant of *A. punctata* rosea, with brilliant blooms; this was more like a large closely bunched bunch of cut flowers than a plant growing in a pot. There were several specimens of *Boronias*, *Eriostemons*, *Clerodendrons*, and *Chorozemas*. *Chorozema varium illicifolium*, although not so large as some of the others, presented a graceful thriving appearance; *Heaths*, *Dracanas*, variegated *Yuccas*, and similar plants were also furnished. Also *Agave Rozeliana*, a fine sharp-spined species, and *A. Regeli macradonta*, with large thick leaves, and strong formidable-looking, crooked spines; *A. Peacockii*, a smaller kind than the former, with crooked spines; *A. elegansissima*, a beautiful pale green glaucous sort, the margins of the leaves of which are densely covered with a line of short spines, inclined towards the heart of the plant, the leaves terminating in acute, sharp points; *A. Besseriana amena*, a smaller kind, with strong spines; *A. Gibbsii*, with short, broad, thick leaves, attenuated by a long, sharp spine, a few being along the margin; and *A. Besseriana glauca*. *Primula japonica* (Paul & Son) was shown, with four flower spikes on one plant, the foliage of which was most luxuriant, each leaf being about six inches across, and the plant about two feet in diameter. It produces seed plentifully. Among herbaceous plants was a grand collection with variegated foliage, including a splendid group of *Funkias*, and other interesting subjects.

First-class certificates were awarded to *Agave Peacockii*, to *A. elegansissima*, to *A. Regeli macradonta*, to *A. Gibbsii*, to *A. Besseriana glauca*, and to *A. B. amena*, all from Mr. J. Croucher, Sudbury House, Hammersmith; to *Adiantum amabile*, to *Croton lacteum*, to *Epidendrum pseud-Epidendrum*, to *E. syringothyrsus*, and to *Acer polymorphum dissectum* from Messrs. Veitch, Chelsea; to *Macrozamia McKenziei*, to *Zamia cycadifolia*, to *Agave Regeliana*, to *Rhopalos elegansissima*, and to *Stock Purple Queen*, from Mr. B. S. Williams, Upper Holloway; to *Hedera concolorata*, to *Pimelea Hendersonii alba*,

TRIAL OF BOILERS AT BIRMINGHAM.

First and foremost in this proposed trial comes the fact that no iron boiler, whether wrought or cast, displays its real working capabilities until the same has been in operation for hours, and I should not exaggerate if I said days, after fixing; therefore if the proposed trial is to continue but for one or two hours, how are the real merits of each boiler to be correctly recorded?

Second.—The quantity of fuel consumed during the first day or two, to produce certain results, is not a correct index of the future daily consumption required to maintain the same. How, then, can a verdict be pronounced upon the very important point of "economy of fuel"?

Third.—With reference to "night stoking." By what process of reasoning can this be adjudicated upon, if each boiler is to be in operation for one or two hours only?

Fourth.—"Economy of labour" is an attribute claimed by more than one maker of boilers for his pet production, and I ask whether a period of less than twenty-four hours' work will yield any practical proof of the daily labour each respective boiler absorbs?

Fifth.—Boilers "foul"—some more quickly than others. It is only a question of degree; but this is just the thing which vitally effects their maintenance of working power, consumption of fuel, and labour in attendance. It is not the trial of an hour or two's duration that will test this.

Lastly.—In so short a time it is impossible for a boiler to demonstrate the command it possesses over its work, and the niceties to which it can be regulated, by producing first a slow circulation, and raising to a great rapidity in cases of emergency. In short, I venture to submit that a trial to be of any value must necessarily be extended over a period far exceeding that assigned to the forthcoming meeting at Birmingham; and if it be worth undertaking at all, it is surely worth doing well.

The trial should be conducted, in my opinion, as follows:—Neither the temperature of the water in, say one thousand feet of pipe, nor that of a conservatory or room, would be of any avail for this purpose, on account of the influences from the external temperature to which these would be subjected. I propose, therefore, to provide an iron tank holding not less than fifteen hundred gallons, fitted with top manhole and plate, all well secured. To fit the same upon a platform elevated ten feet from the ground, so as to avoid the necessity of sinking a stake-hole. This tank is to be enveloped in a wood casing consisting of inch deal, leaving a cavity of three inches on all sides to receive a packing of sawdust, so as to effectually exclude all influence of external temperature; pierce the tank where most convenient at top, and insert a kind of bottom-heat thermometer about three to four feet long, having its bulb two feet in the water with the index exposed, which should be read at stated intervals, and all its variations recorded by properly appointed authorities. Within the tank, and worked from the top, should be placed a kind of plunger to be worked to and fro at stated periods for the purpose of thoroughly mixing the water and producing an uniform temperature throughout the tank. An air pipe to be fixed at top, and a small tap at the side, about four inches down, the former to allow of expansion, and the latter to show the quantity of water in the tank. Bolt on the flow and return nozzles, and extend the same through wood casing, leaving all other connections to be made by each competitor, the tanks would thus be ready to receive the water and commence operations. The distance between boiler and tank to be not less than one hundred and thirty feet, and if one hundred and fifty feet so much the better. Taking it at the former measurement, the top of each boiler should be fixed at a level not exceeding twenty inches below the bottom of the tank, which would give a rise of about one and a half inches in ten feet to the flow pipe.

The fall of the return pipe need not be necessarily identical with that of the flow, so as to render them parallel throughout. Opinions differ upon the advantage of such an arrangement; and, therefore, I would leave it optional with the competitors to adopt whatever plan they thought best. Every competitor should cause his own boiler to be fixed under his personal superintendence, or that of his representative, for which he shall be responsible; also, one or the other of them should be allowed to work the boiler during the entire trial. No results to be recorded by any interested party, except for their own private use and information, but not for circulation. After having clearly defined, by rules and regulations, the relative position and level which each boiler shall occupy in relation to the tank, the size, number, and form of the circulating or connecting pipes between boiler and tank should be left to the decision of the competitor, each competitor being at liberty to remove those used for any former trial, and substitute for them any special arrangement of his own, so as to meet the requirements of his boiler.

For obvious reasons, however, it would be necessary that each

competitor should at the time of making his entry lodge with the authorities a proper plan and specification, setting forth in the clearest terms his proposed plan of fixing the said flow and return pipes; also the number and size of each, together with the level of return pipe; and from this statement and plan, no deviation under any circumstances should be permitted at the time of preparing for the trial.

Such is an outline of my suggestions, which of course require to be supplied with details, a work not difficult to do, if the Society will but declare itself in favour of a properly organized boiler trial.

S.

VEGETATION IN SARDINIA.

Few countries charm the eye more by richness of foliage, abundance of blossom, and profusion of flowers, than Sardinia does. From the almost virgin forest on the higher mountains down to the fertile and often unhealthy valley where fruit and flowers are produced with tropical luxuriance, the varieties are endless—oak, cork and olive, almond, peach, orange and lemon, fruit trees of all kinds, groves of silver aspen, fig-trees growing up everywhere, in the vineyards and by the roadside, and then the hedges covered with an extraordinary wealth of wild flowers. For miles together the waste land, of which there is much on either side of the railway, is covered with a luxuriant growth of the pale pink asphodel, just as are large tracts of ground between Rome and Civita Vecchia. In the valleys one comes upon orange plantations, generally under the shelter of rising ground, for shelter and water are indispensable to the orange, and the side of the tree exposed to an inclement wind is often bare of fruit when the other branches are plentifully loaded. The arbutus, the oleander, the myrtle, the Judas tree, grow wild in abundance, the fruit of the first-named supplying the dessert-table, while the berries of the myrtle fatten and give flavour to the birds. In the spring, however, it is remarkable how few birds are seen in the country, at least in the districts I lately traversed while in the mining regions none whatever were visible. Up to the very mouths of the mines and all over the mountains, on every ledge of rock where a few grains of earth afford roothold, spring myriads of a dark pink cyclamen, one of the delicate treasures of English greenhouses; and up to the very tops of the hedges in the valleys the beautiful blue *pervenche* (Periwinkle), twice as large as any I have seen even in North Africa, where it abounds, trails itself in extraordinary profusion, mingled with a small crimson flowering vetch. The wild lavender, the orange marigold, an immense variety of orchids, the azure bloom of the horseglass, cover the banks, and I must not forget the white heath, a very beautiful sort with black stamens, which grows as big as a good-sized cherry tree, and excited the admiration of the Scottish members of our party. The garden stock grows wild in some parts of the island, particularly the blue Alexandrian stock; the cactus is everywhere, with its dangerous prickles and its mawkish fruit sprouting out of the edge of its leaves, amid which sit small frogs of the most brilliant green, contrasting with the darker and duller hue of the fleshy plant.

Curious Site for a Thrush's Nest.—There are now to be seen in Heywood Gardens, Weshbury, Wilts (the property of Mr. H. G. Luladow), two thrushes' nests close to each other, containing four eggs, and each in a Scotch kale.—C. Squier, in "Field."

THE GARDEN can be had in neatly covered monthly parts.—On sale at all Messrs. Smith & Son's bookstalls. Part V., for April, now ready, price 1s. 5d. Publishing Office, 37, Southampton Street, Covent Garden, London, W.C.

The Name and Address of the writer are required with every communication, though not for publication, unless desired. Letters or inquiries from anonymous correspondents will not be inserted.

All questions on Horticultural matters sent to THE GARDEN will be answered by the best authorities in every department. Correspondents, in sending queries or communications of any kind, are requested to write on one side of the paper only.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

Readers who may find it difficult to procure THE GARDEN regularly through the newsagents, may have the numbers sent direct from the office, at 19s. 6d. per annum 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsagents, at the railway book-stalls, and from the office.

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—Shakespeare.

H O M E L A N D S C A P E S .

GARDEN BEAUTY IN MAY.

(HYDE PARK AND KENSINGTON GARDENS.)

ONDON smoke, as the great sea of houses spreads further and wider, is beginning to tell with sadly destructive effect upon the early spring foliage of our streets and squares. Till quite recently, for a few short weeks in early May, the great city was enlivened with the many soft and bright hues of fresh young leaves of numerous kinds; but now, even in the open, airy regions of the spacious terraces and crescents of Bayswater, as the plague of building spreads around, swallowing up grassy meadows and green lanes without the least remorse, the freshness of the spring foliage has become an affair of days, instead of weeks.

Fortunately, the noble area occupied by Hyde Park and Kensington Gardens seems at present to defy the smoke field, and, from whichever side approached, the first glimpse of the noble old trees, with their massive trunks and arms clothed with their new mantle of green, and the luxuriant foliage of the younger plantations, are, just now, a sight to gladden the eyes and cheer the heart. Entering by the gate in the Bayswater Road, the picturesque leafy forms of the weeping hornbeams, and the aspect of the young horse chestnuts, with their broad and massive foliage, and their great spikes of flower just bursting into bloom, form charmingly luxuriant groups; and following the line of the shrubbery that continues as far as the Marble Arch, other combinations occur that are quite as attractive, with weeping birch and variegated sycamore, and other trees, all equally redolent of the green youth of the year. The laburnums, with their golden rain of streaming blossoms, are partially over; except where, nestling deep among the larger trees, they are shaded from the direct sun rays; and in such situations they are still in all their beauty. The Persian lilacs, also, are past their best, and there are too few of them in this shrubbery; but they are not missed just now, in the midst of the hundred forms of freshly expanding foliage, which are thickening and spreading every day. The white Portugal broom plays its part very gracefully in this plantation; but why is our fine native broom absent, with its rich golden blooms?—the "plante-a-gencet," which was the crest of our Anglo-Norman kings. It is a national plant, and ought to be conspicuous.

The general plan of this belt of fine young trees and shrubs is extremely well conceived; part being densely filled up between the trees with shrubs of a lower growth, while alternate portions are entirely clear of any underwood whatever, and the trunks of the handsome young trees rise direct from the turf, producing a Savannah-like effect of the most pleasing kind. This effect, too, is seen at its best, in consequence of the turf being protected by a slight iron fence, which prevents the destructive feet of shoals of nursemmaids and multitudes of children from treading out the life and freshness of the young grass.

With respect to the flowering herbaceous plants in front of the dense shrubberies, they are neither so well selected nor so numerous as they might be, the patches are scanty, and the variety insignificantly small. Nevertheless, the golden tufts of yellow Alyssum, and sparkling white Iberis, and some

big clumps of purple Iris, with, here and there, touches of deep orange from a few early marigolds, varied by some patches of red Valerian, give us glimpses of floral colouring that are exceedingly pleasant to see.

So far my May ramble in the park was satisfactory; for the freshness of spring, wherever its flowers and foliage are furnished forth with taste, however scantily, disarms horticultural criticism. But along the strip parallel with Park Lane—from the Marble Arch to Apsley House, the portion of Hyde Park devoted to flower-gardening on the bedding system—there was no display at all, either scanty or otherwise. This in mid-May—the month of flowers—seems utterly inexplicable; and yet it is most true. There are the long lines of beds—latey so gay with tulips, hyacinths, and crocuses—absolutely barren, with the dead and mouldy remains of the plants lying rotting on the ground. It may, perhaps, be urged that the beds are waiting for the time of planting-out the geraniums, and verbenas, and calceolarias. Very good; we shall be glad to see those never-failing favourites in due time; but why this hiatus in the middle of May, while there are such abundant means of filling these beds attractively between the tulip and geranium seasons? What more gorgeous effect, for instance, need be produced than a bed of giant purple stocks, alternating with beds of white ones—the edgings to be of the common saxifrage (the favourite London Pride), now in full bloom, or white Iberis, or of yellow Alyssum? And, then, what brilliant effects might be produced to vary these colours by means of double wallflowers, the rich brown kind to be furnished with an edging of pale blue pansies, and the golden yellow with a rich purple variety! I can fancy no finer effects than these combinations might be made to produce in order to fill the gap which is here allowed to become so disagreeably conspicuous between the early spring show and the planting out of the half hardy things for the summer and autumn display.

Going across from the Achilles statue towards the southern end of the Serpentine, the silvery gleaming of the water, seen between the trunks of the fine old elms, and the pale olive foliage of some young poplars, was very charming, backed as it is by the woods of Kensington Gardens, softened into the distance by a sunny veil of thin May mist. The enclosures in this part of the park, in which the turf is kept mown, are a very pleasing feature, beds of the tropical-looking Yucca and masses of Rhododendrons, some of them in full bloom, doing duty with marvellously good effect.

The rockwork and the valley with a winding brook-like streak of water, are features which are just now seen to great advantage, the grass of the valley wearing its freshest green. It is kept nicely mown, and the simulated stream is bordered with occasional masses of rock, entirely clothed with ivy, which make a very pretty picture. The rockwork, strictly so called, is certainly open to criticism. The "rocks" composed chiefly of over-burnt refuse bricks, are decidedly offensive where the vulgar material is left conspicuously bare; and there are a few disfiguring spruce firs, which, having been stuck in places where it was impossible for them to grow, are already quite dead, and ought to be removed. Dwarf furze is flowering upon this so-called rockwork in wide patches; the pretty London Pride enlivens it with its sparkling spikes of pink and white flowers; and Vinca, blue and white, with many other spring flowers, make it very gay and full of colour.

Round the south end of the Serpentine, where a few years ago there was only a bare brick wall and an ugly stone coping which formed the termination of the water, there has been much improvement. A sloping bank of green has been contrived, which is beautifully kept, and so soft and velvety-looking is the turf that the stately swans were tempted from the water on the morning of our ramble, and lay basking on the green slope with most picturesque effect; making a fine contrast of colour to the great clumps of dark-leaved Rhododendron, partially in flower, with which portions of the green bank are studded.

In Kensington Gardens, the bridge walk, where it becomes a long flower walk, is just now the most pleasing feature. The hawthorns—white and red, double and single—are in all their beauty, and fill the air with fragrance; and to add to the charm, thrushes and blackbirds are singing loud and

cheerily, as well as several kinds of migratory birds, that only visit us for the spring and summer months. There is nothing finer in Europe than this long, partially shaded walk, with its front borders of gay flowers, the shrubs behind, chequering the warm-toned gravel with their soft grey shadows, that move and dance and change their shapes with every breath of wind. At two or three points, breaking forward from the line of shrubs, are weeping hornbeams, of picturesque growth, which form irregular arches athwart the path; and beneath these green arches the passing to and fro of the gaily-dressed crowd makes just the kind of picture that Watteau would have delighted to paint.

The flower borders on each side of this delightful walk are profusely furnished with the ordinary flowers of the season; great masses of Iberis, dazzlingly white; clumps of pansies, purple, yellow, and lilac; and fine single peonies there are, but not enough of them; and why only the crimson variety? and why no double ones—those glorious carmine spheroids that loll over the box edgings of old-fashioned gardens with such imperial splendour? Yet, notwithstanding the absence of these aristocrats of flower borders, there are many grand old favourites enjoying themselves this fine May day along the sides of the Kensington "flower walk." There are also a few now ones, especially several varieties of a very attractive new anemone, which shows that the authorities who rule over the arranging of these pleasant walks of our great city parks are not sleeping. In short, although it is said that the funds are so very grudgingly supplied, Hyde Park and Kensington Gardens afford a very fair sample of "garden beauty in May," and they will do still better in June.

May 13, 1872.

NOEL HUMPHREYS.

NOTES OF THE WEEK.

— ONE of the most curious phenomena connected with the late eruption of Vesuvius has been its effect on the trees. The heat of the lava was so great as actually to boil their sap, and to cause them to emit noises of the strangest character. A moment later and they were destroyed.

— A NEW fountain has been opened in the broad space in the central transept of the Crystal Palace. It throws up an extremely high jet, and the water falls in a graceful shower, which, when the sun shines on it, has a charming effect. This fountain is surrounded by flowers and foliage plants, and is a welcome acquisition.

— At a late meeting of the Linnean Society, Mr Miers exhibited a textile material, says *Nature*, which he had received from the Brazilian Government, and which it was thought might, to a certain extent, become a substitute for cotton. It is a product of the liber of a climbing plant of unknown relationship, and can be procured in any quantity, furnishing a fibre of very strong and silky texture.

— HYDE PARK is said by Mr Jacob Larwood to have been first opened as a pleasure ground to the public by Charles I., some time before 1637, and even up to the close of the wars with Napoleon, it retained its rural appearance. "Cows and deer," we are told, "were grazing under the aged trees; the paths were few, and none told of that perpetual tread of human feet which now destroys all idea of country charms and associations."

— AT a late meeting of the Royal Botanic Society, the secretary reported the receipt of several seeds of the South American india-rubber tree (*Siphonia elastica*) from Para, Brazil, in fine condition. This tree, although supplying the market with the most valuable samples of india-rubber, is scarcely known in Europe, and it is doubtful, it is said, whether a specimen is alive in any garden in England at the present moment.

— The *Maidstone Journal* says the fruit crop this year appears to be almost a total failure in most districts round Maidstone. The earlier sorts of cherries were cut up by the severe frosts, but of the later ones there is a probability of an average crop. Gooseberries and currants have been great sufferers from the weather. With the exception of a few favoured spots the crop of plums will also be short. Apples have blossomed very badly this year, and are likewise suffering from an attack of maggot. There is every appearance at present of the fibres being attacked by the caterpillar, as they were last year, but, as in some districts the trees are looking strong and healthy, they may eventually escape. Considerable damage was done by the severe frost on Saturday night last.

— THE climate of Shetland has generally been supposed to be little better than that of Iceland, whereas the mean winter temperature is higher than that of Edinburgh. It is a remarkable fact that the winter climate of the west coast of Britain, everywhere higher than that of the east coast, scarcely varies from the south of Wales to Shetland. The winters of Shetland are so mild that snow never lies long, and the lakes and ponds are rarely frozen so hard as to bear a man's weight.

— WOODEN pavement is now stated to be superseding the asphalt paving in Paris. This is what is called the patent Ligno-mineral paving of Trenaunay's system, and was reported upon by the French engineer, Alphonse (Baron Haussmann's right-hand man), as having satisfactorily undergone very severe tests. It has also been used on the bridge at Rome; and we understand that the agents in this country have made arrangements with the City Commissioners and their engineer, for paving a portion of Gracechurch Street, adjoining the new asphalt roadway, with blocks of Ligno-mineral, at 12s. 6d. per square yard.

— CAPTAIN HALL, the Arctic Explorer, says the *New York Times*, has obtained evidence that a genial atmosphere prevails at times in the extreme undiscovered north. For instance, it is asserted that plants were found in the ice which are indigenous to southern climates, and that a floating stick of wood was met with in the middle of January, which proved, on examination, to be a limb of a huge birch tree. But stranger than all is the statement that Captain Hall was able to sit on deck all through the night of the 14th of February reading, writing, and making lunar and astral observations. After this it is not surprising to be told that throughout the whole month of January little ice was seen, and that each night the sky on all sides glittered with meteors of the most gorgeous description.

— THE island of Majorca abounds in fruits. These consist of olives, grapes, almonds, oranges, figs, lemons, raisins, nuts, capers, and the fruit of the cactus, or "prickly pear." The principal harvest, however, is gathered from the almond tree, the cultivation of which is a source of great profit. No part of the tree is wasted; with the use of the inner kernel of the fruit we are all acquainted, but even the hard outer covering forms capital fuel for small stoves. Then, the outside of the fruit is largely used in the manufacture of almond soap; and when the tree itself is cut down, the stem is manufactured into household furniture. As regards appearance—who could fail to be impressed with the beauty of a field of almond trees in full flower? Seen from a hill, the trees look as if covered with minute flakes of snow, while by moonlight the same effect is rendered still more striking.

— It is proposed to build a grand marine aquarium at Manchester, the funds, for the carrying out of which, are to be raised by a company. The building is to contain all the recent improvements shown to be necessary at the Crystal Palace and Brighton aquaria, and will be rectangular in shape, 120 feet long and 70 feet wide. This space will be divided into two side galleries, each 120 feet long and 15 feet wide, separated from the central saloon by a slight screen. Running along one side of each of these galleries, will be a series of tanks, about eighty in number, forty in each gallery, varying in capacity from 300 to 3,000 gallons. The grand saloon will be also 120 feet long by 40 feet wide. All the windows will be so arranged as to admit only the exact amount of light required, as it is found that an access of light acts upon the higher marine plants and animals in a manner directly contrary to its action upon terrestrial life. It blanches them in a similar manner as ordinary plants are blanched by being earthed up. The most brilliant coloured marine plants are those which live in comparative darkness.

— THE weather was very cold in London on Saturday last, and there was a slight fall of snow and hail. From almost all parts of England the prevalence of cold and stormy weather is reported. At Bristol, on Saturday, the storm of snow, hail, and rain lasted for nearly an hour. While the storm passed over Frome the darkness was so intense that the tradesmen found it necessary to light the gas in their shops. The flakes were of an extraordinary size, and snow fell incessantly for nearly an hour. There were several other slight falls of snow during the day. Snow also fell in Kent on Saturday, and on Sunday morning there was a severe frost, which has done considerable damage to the potato plants and some kinds of fruit. At Shields on Saturday night the weather was very stormy; the wind was from the north-east, blowing a gale, and there was a rough sea. There were several showers of hail during the day and the air was extremely cold. The weather of Friday and Saturday was very boisterous and cold in North and East Yorkshire, and on Saturday morning snow and hail fell, the hills being quite white. Early potatoes have been destroyed. Many of the market gardens near Paris have suffered considerably, and the same is the case with the vines in the south of France.

THE GARDENS OF ENGLAND.

COMBE ABBEY, COVENTRY.

THESE articles must not be regarded as in any sense descriptions of the places with which they are connected. They are simply notes of observation referring to the most interesting or instructive features of each garden visited, and, as such, may perhaps prove useful to such lovers of gardening as may be attracted to this part of the country by the forthcoming show of the Royal Horticultural Society, to be held at Birmingham. As, however, in the course of our progress through the country many places will be visited of which no sufficient idea could be given by these short notes, it is proposed to describe and illustrate at length all the really instructive and remarkable gardens. This will be done as time will permit for the proper selection and execution of engravings, which will speak to the eye more eloquently than words.

LANDSCAPE AND WATER.

The park at Combe, dotted with its old trees, is a fine one; but, like many others, its beauty and extent are sadly marred by wooden fences and other dividing lines, which could be well dispensed with. Therefore, in point of landscape beauty, it is nothing to what it might readily be made. Its noblest feature is the fine piece of water, which is one of the best artificial pieces I have seen. It is more like an elbow of some broad river reach than what, in parks, is commonly called a lake; but, as regards outline, the mode in which the grass banks approach it, or in any other way, there is not a false line about it. In this respect it contrasts well with the numerous half-stagnant duck ponds which, in the midland counties, are commonly placed under the windows. But—unhappily, there is a very important “but”—some years ago a “moat,” or what is simply a stone-walled canal, was taken from this perfectly natural-looking piece of water straight to the house. It passes close under the walls flanking one side of the Abbey, the drive to the forecourt passing over it. There are many foolish things done by those artists who, instead of meeting modern wants by the best expression of modern skill and knowledge, ignorantly imitate the creations of a long-buried past. But, surely, this disfiguring of a noble lake, and this digging of an ugly canal under the walls of a stately house, is the feeblest notion that has ever been carried out in our own day! Let us cherish the past by all means; it is right to preserve every morsel of it that remains to us; but let us not, in startling disregard of the fitness of things, prove ourselves contemptible to all clear-thinking men, and to coming ages, by fudging up a brand-new and distorted likeness of such a thing as a moat—a necessity, if not a beauty, in its own long-buried time. This unhappy canal, with its accompanying walls, completely cuts up and distorts the best sides of the Abbey, renders the highly important need, called by landscape gardeners “breadth,” impossible, spoils the end of the lake nearest to the mansion, distracts with its adjuncts the eye from surveying the old or new portions of the building, and renders necessary certain ugly terraces of earth. These were thrown out of the canal so as to intercept the view of the lake from the Abbey. The landscape features of the garden suffer some what from the large oblong kitchen garden being placed right in the middle of the pleasure grounds; but many improvements are in progress, which, by extending the planted grounds in other directions, will modify this drawback.

TREES.

Here, as in many places in the country, the grand old native oaks are the tree kings yet. They dot the park like giants of a past age, and look on and see generations of men pass away like leaves, much as rocks or old castles do. Fine groups of Scotch fir, which must ever remain one of the princes of the ornamental trees that attain perfection in our clime, share with the oak the glory of the park. The Cedar of Lebanon has done little or nothing for it. The Deodar Cedar seems to thrive better. Of this there is an avenue about two miles long, very few or none of the trees showing signs of the debility they so often manifest. In this long avenue, which is outside the garden proper, it is interesting to see how the Deodar thrives, often overtopped by common forest trees and half choked by briars, or injured by deer. It seems a pity that such a very remarkable avenue of this noble tree—which, by the way, thrives much better in Warwickshire than one would expect from its usual condition near London—should not be enclosed and taken proper care of. None of our most famed arboreta have a finer feature than this would prove if taken care of. The long drive, bordered by these Deodars, seems a capital site for an arboretum. A selection of evergreen and deciduous trees known to thrive well in the midland counties would soon place it in the front rank of arboreta.

The tree mammoth of the Sierras (*Wellingtonia*) thrives apace here, not one of many specimens being diseased or slow-growing,

The giant of the Canadian woods, *Pinus Strobus*, in its own home and in favourable situations one of the noblest trees, does fairly here, there being a good many picturesque old specimens planted some years ago. They usually break into several leaders, and do not form one grand stem, as at home. This is probably owing to the smaller degree of vigour attained under our feebler sun. The tree, however, thrives so well here as to warrant its being extensively planted for ornament. The Araucaria also does well, though not quite so well as the *Wellingtonia*; but those fine trees of the northern parts of the Pacific coast, Lawson's Cypress and the Nootka Sound Cypress (*Cupressus Nutkensis*), seem as much at home as they are on their native hills. There are many hundreds of *Cupressus Lawsoniana* raised from seed, every specimen a fountain of graceful form and perennial verdure.

This kind has been much grown from seeds here, and, like most of the conifers experimented with, always grows much better if undisturbed. Mr. Miller finds they dislike moving more than is commonly supposed. The American scarlet oaks are very fine, and now (May 8th) almost as attractive as clouds of peculiar lemon yellow, as in the “fall” when in the deep flush of their autumnal glory. It is to be regretted that such trees are not sometimes grouped in our parks. Here, in Warwickshire—where our common native deciduous trees form such noble specimens—I saw a *Wych Elm* the other day nearly thirty feet round the stem; many fine deciduous trees—hardy exotic trees, that come from countries often colder than our own, would thrive nobly. And if the American oaks thrive as I have seen them do in some of the hangriest lands of central France, as, for example, on M. Vilimor's old estate, at Des Barres, in Loiret, they may well be expected to become noble trees in the parks where our British oaks attain such stately dimensions and spread out widely and so inflexibly in the teeth of the winds. Here, as in nearly all parts of the country, the Spanish *Picca* thrives well, and proves itself one of the conifers fearless of our clime. The Virginian Cedar is seen here, and in other places in the neighbourhood, in tall well-developed specimens, with that close erect cypress-like habit which one sees so often marking the mountains and hillsides of the western parts of New York and many parts of the Eastern States of America, as emphatically as the Eastern Cypress does the cemeteries on the Bosphorus. The value of this very hardy and beautiful tree as a close-growing, tapering one does not seem generally known, otherwise we may presume it would be extensively planted where the Eastern Cypress (*C. sempervirens*) perishes from cold.

A PLEASING FEATURE IN THE PLANT HOUSES.

This is shown in the utilisation of spaces usually unoccupied in gardens—those under the beaches to the right and left of the footways through the houses. Here is a large cool house with a collection of greenhouse plants; but over the pathway leans the numerous fronds of a fine collection of British and hardy exotic ferns, planted on each side of it. In a pinery, there are as healthy seams of the Maiden-hair Fern springing from beside the footways as ever graced the rocks by an Italian roadside. Here is a plant stove, in which from the ground beneath the pipes and beside the footway springs a mass of beautiful plant life, with a grace and abandon impossible in pots. The richly-spotted leaves of the Caladiums, leaning forth from masses of Maiden-hair and of coral-berried Rivina, look more effective than ever they are seen in pots; while here and there the large-leaved palm-like *Panicum sulcatum* gives quite a tropical cast to the little groves that so well adorn the footways. In a warm fernery, tropical species are planted out in like manner, and the result is of the most charming kind. Mr. Miller intends going a step further, and arranging his shelves above these little plantations so that a graceful drapery of plant life may be established thereon. Simple as this kind of improvement is, there is none more desirable. We have too much of the glass shed visible in our hothouses; they are too angular, and contain too many needless disfigurements. It must henceforward be the pride of the gardener to rob these structures of their nakedness, as Mr. Miller has done here in such a successful manner. By planting thus, three things are effected. First: Space usually considered useless is occupied. Secondly: Valuable collections of plants are grown with infinitely less trouble to the cultivator than when they are grown in pots; and, Thirdly: The aspect of the houses is immensely improved. Surely, if so much can be done in a formal lean-to house, we need not despair of doing more in our conservatories and houses specially designed for ornament. There is no way in which we may effect more improvement in our houses than this; and it is not merely the effect which is so desirable, but the immense saving of harassing labour to the gardener which the planting-out system at once secures. Besides, if the temperature is suitable, the planted-out subjects usually do much better than in pots with ordinary culture. In the warm fernery here, the long, feathery, coral-laden and weeping shoots of *Russellia juncea* and the rich crimson blossoms

of the racemose Passion-flower (*Passiflora princeps*) lend quite a novel charm to the grace of the ferns. We are too apt to isolate ferns from every brilliant flower that intensifies their grace. The fernery, outdoor or in, should not be a mere collection of fronds; as in their own haunts they are accompanied by plants the glory of which is in their blossom, so should they be in gardens. Among our choicest hardy plants, there are many, like the White Wood Lily (*Trillium grandiflorum*) and the Moccasin-flower (*Cypripedium spectabile*), which thrive in the very conditions suitable for hardy ferns; and the same may be said of flowering stove plants and ferns.

PALM GRASS (*PANICUM SULCATUM*).

This is the handy English name I propose for a noble palm-like grass now easily obtained in our gardens, but which I have never seen employed to such good effect as in the gardens here. In addition to growing it in pots, Mr. Miller plants it out in the houses in various positions, the result being an effect as good as is afforded by any palm. And it will prove of greater use in our gardens than any palm, because it can be raised from seed as easily and grown as quickly as *Tropaeolum* or Indian Corn. The following is Mr. Miller's simple mode of treating it, kindly furnished by himself:—

"Wherever the plant is introduced it grows luxuriantly and seeds freely; the seed comes up everywhere, and if it does so in places where it is not wanted, it is easily removed. When grown in pots for decorative purposes, the effect is as fine as anything produced by the most expensive palms we have. If by exposure or frequent use plants are injured, the loss is not much, as they are easily and quickly raised. A pan of seed sown in a little heap will produce in two or three months nice plants for purposes of decoration. The plant when fully grown throws up leaves from two to four feet long, and a graceful stem often to six feet. As to soil, it is not particular, growing equally free and handsome either in sandy loam or peat, or any free soil that may be at hand at potting time. The seed ripens continuously through the summer and autumn, and may be sown at any time."

FRUIT.

The gardens at Combe are among the most remarkable in the Midlands for their extent and good management, and particularly in all that relates to fruit growing and fruit forcing. I have rarely, if ever, seen a garden in which the vine and the peach show more skilful culture or yield better results. There is nothing that is new to say of the system applied to either. As to the peach, it is simply the good old plan of training over the roof that is chiefly employed; the back walls being also covered in each case with fine healthy fertile trees, luxuriating in two or three feet of sound loam on well drained borders, both within and without the house. This good old system, however, and a like one applied to the vine and other fruits, sufficed to carry off the prizes for collections of fruit at the chief fruit shows in the Botanic Gardens, Regent's Park, for three years in succession. Peaches are also grown to perfection in a peach-case sixteen feet high and eight feet wide. This affords as fine an example of perfect peach culture as could be seen, both the erect trellises in front and on the back wall being regularly covered with healthy abundant-bearing trees. All peach-cases are, however, to some extent mistakes. The peach-case seems at first sight a plan for cheaply covering and protecting a wall; it is really one for building a peach-house much less useful to the cultivator than the old lean-to. For there is only room in it to grow the fruit and gather it, whereas the ordinary lean-to, half-span, or span gives as much space beneath the trees as if no fruit were grown overhead, and for half the year we enjoy good light for plant growing in this space. I believe there is only one peculiarity in Mr. Miller's peach culture, he fumigates, before he sees any aphis, just as the infant peach buds are beginning to burst. The orthodox rule is, "fumigate on the first appearance" of that devourer of our hopes. The peach trees at Combe are mostly trained on the Seymour plan, i.e., making all the young and bearing wood spring from the upper sides of the branches. The system of training, however, adopted with the peach is of but little moment. The plan that will cover the walls quickest will one day be adopted by all intelligent growers.

As to the grape—it's culture here is of the most superior character, and on the old spur system. Here, again, we have nothing new to say. Mr. Miller does not densely cover his borders with litter, &c., as is often done; nor does he otherwise protect them, considering that, if the borders are in proper condition, the rains do not hurt the vine. That singular and noble-looking plant, the *Monstera*, reputed to be a valuable tropical fruit, is here abundantly fruited. Planted out pretty near the glass in the pit of a pine stove, and in the full sun, it grows freely, and fruits in half-shady and shady positions in stoves; but the treatment given here is likely to bring out better any virtue or merit this slightly over-praised fruit may possess. The melon here—grown as is now usual in neat low houses—is kept a little cooler than is the rule (60° at night, rising 15° to 18° by day), the result

being a much firmer growth and greater freedom from insects than is common. *Passiflora edulis* is preferred to any of the edible Passion-flowers—as well it may be, for all the other kinds are almost flavourless. Stevens's Cornish boiler has recently replaced a tubular boiler for the heating of all the houses here, and with satisfactory results.

In the open garden the condition of the fruit trees is also admirable. The very extensive kitchen garden is enclosed by walls perfectly covered with well-formed trees, and the walks are margined by numerous large and well formed pyramidal ones. A good many of the trees are also trained in what may be termed dumb-waiter fashion—gradually lessening tiers of evenly disposed branches. These are the best of their kind we have seen in the country. Peach culture in the open air is very much written down nowadays, and is frequently supposed to be impossible. There is a wall of trees here trained on the Seymour plan, every foot of the surface properly covered by healthy bearing wood, which ought to convince anybody of the perfect practicability of growing the peach in the best condition in the open air, in any of the midland or southern counties of England. It is a real loss to progress in fruit culture that any such idea should have ever gone forth. It is no wonder the amateur despairs of its culture when he sees the melancholy result of leaving walls without a wide temporary coping to throw off sleet and prevent killing frost during the dangerous season. But the fact is that with properly-managed and protected walls, as carefully guarded from insect pests as our best peach houses are, as fine peaches as were ever eaten may be grown over the greater part of England and Ireland.

We shall again return to and illustrate the more instructive features of this fine garden.

HOW RICE PAPER IS MADE.

BY E. C. LEFROY.

The Rice-Paper plant (*Aralia papryfera*) grows naturally in China and Japan, where the inhabitants carefully cultivate it upon the hills and high-lying ground. In the autumn of each year, before the leaves fall, the Japanese cut off the young shoots, and cut them into slips, which are tied up in bundles, and boiled in large copper kettles or cauldrons closely shut down. The boiling is continued until the bark has peeled off the wood, when the former is carefully dried and stored away for future use.

When it is required for paper-making it is thoroughly soaked in water for three or four hours, after which the brown skin is scraped off. At the same time the bark which covered the younger shoots is separated from the older and tougher sorts, from which an inferior kind of paper is made. Bark which has been kept for some years is only fit to make the commonest packing paper, and is manufactured with less care. When the bark is well cleaned, and arranged in order according to its quality, it is again boiled until the matter separates into a filamentous substance. This boiling is succeeded by another operation called washing, which is of great importance in the manufacture of the paper. If it is not continued long enough the paper will be of a coarse quality; and if, on the other hand, the substance does not receive enough boiling, the paper will be very white, but too soft and greasy to write upon. The pulp is placed in a basket which will admit the water on all sides, and this is plunged into a river and stirred about with violence for some time. Then the substance is placed upon a smooth table and beaten with wooden rollers. After the beating, an infusion of rice is poured on it, and the mixture is suffered to stand until dry, when the substance is raised leaf by leaf in the form of paper. These leaves are placed between boards, and the remaining moisture gradually pressed out. According to another account the stem is cut into lengths of ten or twelve inches, and the pith forced out and placed in hollow bamboos, where it swells to its natural bulk, and dries into a compact mass. This pith is cleverly cut by a workman, who holds a sharp knife against the side of the cylinder, which is then turned round, so that the pith is cut into a broad strip about four feet long. This is cut up into small squares, and sold in packets for different purposes. It is supposed that the paper made from the pith is the rice paper which is imported into this country. It cannot be made until the tree has attained a considerable bulk, and is too old to produce many shoots, such as are used in the first process.

The tree from which this paper is made is particularly abundant in the island of Formosa. It is at first a small shrub, but after flowering it throws out several branches, and grows to a height of about twenty-five feet. It is generally cut down before it attains its full maturity, because the pith and bark degenerate in the older parts. Several large palmate leaves crown the stem. It has been supposed by many botanists that there are two or three different species of plants from which the Chinese make their paper and there are, apparently, several ways of manufacturing it.

THE FLOWER GARDEN.

ARALIA CANESCENS.

In the size and beauty of its leaves this is far before many "foliage-plants" carefully cultivated in our hothouses at a perpetual expense. The specimen of this species here figured was one of a batch of young plants growing in the Fulham Nurseries. The engraving falls far short of rendering the beauty of the plant. It is easy to imagine what a graceful effect may be realised by such an object, either isolated on the turf near the edge of a shrubbery or grouped with subjects of similar character. Success with this plant may be secured by, first, selecting a sheltered and warm position, so that its noble leaves may be well developed, and not lacerated by storms; secondly, by giving it a deep, free, and thoroughly-drained soil; and, thirdly, by confining it as a rule to a simple stem, so that the vigour of the individual may not be wasted in several branches. The effect of a plant kept to a single stem, as shown in our illustration, is always much superior to

Aralia canescens (japonica)—Hort.

that of a branched one. Young plants present this aspect naturally; but old ones may be cut down, when they will shoot vigorously. As regards position, it is admirably suited for isolation or grouping with other subjects of like character. It is commonly known in gardens as *Aralia japonica*.

HARDY PLANTS IN FLOWER ROUND LONDON.

I WAS very glad to see your list of these last week. But your "reason" for giving it seems to me very inadequate. It will enable us to "keep our outdoor gardens gay," is your modest estimate of it. Permit me to tell you what such a list will do, if you do it well: it will let many of us garden-lovers who have not time—who could find time to go through the London nurseries, botanical and private gardens, every week?—know what is in cultivation in the country. In last week's list, for example, I find several dozen plants that I did not think were in cultivation. This, I need not say, was very interesting to me; besides, you gave me some idea as to where to look for novelties of this kind. I presume the name added to some kinds indicates the name of the person in whose gardens rare or new kinds are. I think it would be better if you gave the garden or nursery, as the name alone is not of much use to persons who do not know these growers; and,

besides, it looks too much like the authority for the species which is usually affixed in botanical books.

Your list of hardy plants in flower round London will also, I think, open the eyes of some of those who think they have gardens around them, while perhaps in the month of May there are not six kinds of flowers to be seen, and these, it may be, occurring by chance. I have seen many gardens of late in which there was not a single spring flower—noting but great hungry expanses of brown earth waiting to be filled with bedding plants when the season permits. *Five hundred kinds of hardy plants in flower in one week*, may, I say, open their eyes.

Then, again, as a simple record of fact, how valuable will such a list prove to lovers of plants or students of meteorology! It will, I think, be highly useful to ourselves, and perhaps more so to those who come after us. To these a faithful record of the blooming period of many flowering plants in some well-known district like London, of which the climate had been well studied, would certainly prove useful, probably in more ways than we now know of.

To gardeners or amateurs who have to embellish a place for a particular season, the lists, if continued, will be of incalculable value. Many gardens are only visited by their owners at a certain season; but where have we a trustworthy guide now if we seek to know the hardy vegetation that may be expected to bloom in any given month? I have myself sought for information on this subject, both in the French and English languages; and though it is a point to which French authors have given more attention than we have, there is no help to be found in them that is worthy of the name. But persevere in your GARDEN lists; make them as full as our collections will admit of, and, after a time, all those who want to know the materials wherewith to embellish a garden at any given season will only have to turn to your pages and find the plants that bloom at that particular period.

Other advantages might be named, but enough has been said to prove the importance of the lists, if well done. On that a good deal depends. The lists must not be merely a record as to what plants flower in any one place, however large, or of any one London district. No synonyms should be given, as one object of the lists should be to let us know what really distinct plants we have in cultivation. I think your *Iberis coriacea* in last week's list is the same as *I. correzeifolia*, just below it.

J. N.

[Our lists are made by two special reporters, who will make weekly visits to all good collections of hardy trees, shrubs, and herbaceous plants within a radius of ten miles of London. Sometimes distinct and valuable plants are known only by their garden names, and these we must give in the absence of others.]

NEW YELLOW VIOLETS.

AMONG the earliest of our winter-blooming plants may be classed the various forms of *Viola lutea* that have been so freely produced of late. They gild with bright colours our generally dull spring gardens, giving masses, lines, or circles of rich golden and pale yellow hues, to be appreciated by those who have seen them so employed. A very few years ago the old *Viola lutea* came much into request, perhaps scarcely in its old form, but in somewhat improved garden varieties. As soon as *V. lutea* came into demand, seed of it was in request also, and from seed there were obtained many large-flowering types, popularly termed *V. lutea grandiflora*. These larger-flowering varieties appeared concurrently in several quarters, and without being, to all appearance, the products of any special attempts at cross-breeding or fertilization. In point of colour all followed the parental type, but some became deeper, others paler, and a few of such a pale primrose as to be almost white. With increased size came also the florist's desideratum—decided advance in form, and with this were also combined the flatness and stontness found in the pansy. Seed from these produced in its turn even larger types; and now flowers having the size and almost the form of the florist's pansies are by no means uncommon, and with but very little departure from the compact, free-branching, and free-blooming habit of the Violas. A marked precocity and an uncommon durability characterize these flowers. Being at the same time precocious and abundant, they are gradually and surely taking the place of the

yellow pansy in our spring flower gardens. Unlike the pansy, they do not succumb under the hostile influence of the hot, sweltering summer sun, but continue in beauty the summer through. I have now in my garden a circular band of one of the most useful of the grandiflora type, known as Yellow Dwarf, because of its peculiar carpet-like habit. It occupied all last summer, and still continues to occupy, a very exposed position, with scarcely a particle of shade being thrown across it the whole day long. During the continuance of the summer drought, pansies, carefully watered and tended, were completely frizzled up; but the Viola held its own bravely, and continued to bloom until the beginning of December. It was then lifted, the soil of the bed renewed, and replanted. By the second week in February it was a perfect circle of glittering yellow blossoms that, it is not too much to state, almost hid the foliage beneath. Equally valuable are a few of the pale sulphur-coloured varieties, and notably Sulphur Queen, which is quite as precocious and, at the same time, as free and durable. Q.

ASPLENIUM SEPTENTRIONALE AND ALLOSORUS CRISPUS.

Yours correspondent (see p. 478) states that he cannot get these ferns to thrive. I have tried a few plants of both, but they don't succeed so well as I should like. One thing against them is their being generally lifted from their native habitat during summer, when in full growth; as an instance of this I enclose fronds of *Asplenium septentrionale* from a plant which I lifted Feb. 14th; the small fronds are those that were on it at the time, the larger ones those that have grown since, while those that are coming are going to be larger still. When lifted during summer it never did so well. It should be planted in sandy peat, mixed with bits of sandstone or decayed trap, and must have thorough drainage, with a south or south-west exposure. If grown in pots, I find it to succeed best in small-sized ones plunged inside larger ones. As nature is the best guide to follow, I may mention that this Fern grows in "cracks" on the south face of trap rocks, even where there is no appearance of any kind of soil, so that the wiry roots must penetrate a long way to withstand the droughts of summer.

The natural home of *Allosorus crispus* is among the *débris* of porphyritic rocks, at an elevation of from one thousand to two thousand feet above the sea. I have observed that the strongest growing plants have generally a large stone over the crown. A north-west exposure appears to suit this Fern best. It dislikes lime, and grows best, I find, among fibrous turf with a large admixture of stones. When planting, keep the crowns of both this and *Asplenium septentrionale* well up, so that water may not lodge about them. Has your correspondent tried barley awns or sawdust as a sing "fence?"

A. B.

FLOWER GARDEN DECORATION.

This is now everywhere receiving a considerable amount of attention; and a free interchange of ideas on the subject may not be without interest. Mr. Baines opened the campaign with a condemnation of the present bedding system, and in No. 24 your correspondent "W. W." makes brilliant charge on our masses of bright colour, that must clear everything before it. I think, however, that he is laying the lash on too heavy when he says the modern gardener is a "cross between extravagance and vulgarity"; for whatever may be our failings, most of us are becoming awake to our position, and, therefore, I trust there is hope for us. We are anxiously looking for light to enable us to get out of the quagmire into which we have been led, quite as much by our would-be guides as by our own proclivities. We must go back to nature for our studies, it is said, and with this I entirely agree. And as a reaction has set in, do not let us run into the opposite extreme, and turn all our grand gardens into wildernesses. The late Sir G. C. Lewis, in writing about the gardens of the ancients, said "they were not gardens at all, but only shrubberies, with bits of statuary stuck about them." Let us try to avoid falling into this error. Some of the arguments that have been used in favour of the natural style of gardening would suggest the inference that the natural style is a continual mixture; but this is not consistent with the real facts, for nature when left to herself frequently plants in grand bold masses, far outdoing the puny efforts of man. But nature tones down her bright masses of colour by masses of foliage, ever varying in form and tint; and, by the light and shadow caused by undulations of surface, softens and renders pleasing what would otherwise be wearisome.

Whatever may be the future of ornamental gardening, I trust the reduction of the present bedding system within reasonable

limits will ultimately be arrived at; and, as regards the present, I would urge your readers to study carefully the remarks of Mr. Westland on the "Flower Garden for May," at page 532, as I think it is in the direction he suggests that an immediate improvement may be looked for. So far as I have seen, the prevailing fault of garden decoration is the preponderance of bright colours.

Ramsey Abbey.

E. HOBDAY.

THE ALPINE GARDEN.

(Continued from page 542.)

PATHWAYS.

No formal walk—that is to say, no walk with regularly-trimmed edges of any kind—should ever be allowed to pass through, or even come near, the rock-garden. This need not prevent the presence of properly-made walks through or near it, as, by allowing the edges of the walk to be a little irregular and stony, and by permitting dwarf Sedums, Saxifrages, *Linaria alpina*, the lawn Pearl-wort, &c., to crawl into the walk at will, a perfectly unobjectionable effect will be produced. In every case where gravel walks pass through ferneries or rockeries, and are fringed by stonework, a variety of little plants should be placed at the sides, and allowed to crawl into the walk in their own wild way. There is no surface whatever of this kind that may not be thus embellished with interesting subjects. Violets and ferns, *Myosotis dissitiflora*, &c., will answer for the moister and shadier parts, and the Stonecrops, *Saxifrages*, *Arenarias*, and many others, will thrive in more arid parts and in the full sun. The whole of the surface of the alpine garden should be covered with plants, except the projecting points or crags; and even these should be covered, as far as possible, without completely concealing them. In moist districts, such alpines as *Erinus alpinus* and *Arenaria balearica* will grow wherever there is a resting-place for a seed on the face of the rocks; and even tall and vertical faces of rock may be embellished with a variety of plants; so that there is no excuse whatever why any level, earthy surfaces should be bare.

WATER.

It is not well to endeavour to associate a small lakelet or pond with the rock-garden, as is frequently done. I do not remember to have met in alpine countries with any crowds of brilliant alpine flowers in the vicinity of small pools of grimy water; indeed, they usually crowd on high above the lake. If a picturesquely-arranged piece of water can be seen from the rock-garden, well and good; but water should not, as a rule, be closely associated with it. Hence, in places of limited extent it should not be thought of at all. If a pure rushing streamlet, with one or more cascades, can be introduced near the rock-garden with good effect, so much the better; but these things are better treated as incidental features.

No formal bridge should ever be tolerated near a rock-garden; it is so easy to form more natural-looking bridges by placing rocks or stones in the streams or arms of water which it is wished to cross. If well done, the footing will not be in the least insecure, and the water will flow between the stones, and graceful water plants crowd up near and between them. It need hardly be added that the rustic arches so common should also be avoided.

Where a large rock-garden is being made, and where expense is no object, water should, if possible, be "laid on," as, without command of a strong pressure and a liberal hose, it is very difficult to water an extensive and elevated rock-garden thoroughly, and very troublesome and expensive even to do it badly with watering-pots, &c. Several taps or outlets will be required in large rock-gardens.

SNAILS, ETC.

Snails are frequently so destructive, that it has been considered desirable to construct a small rock-fringed streamlet round portions of the rock-garden containing the subjects most likely to suffer from them. This is not generally to be recommended, because of the difficulty of doing it well; nor is it generally necessary, inasmuch as the things commonly grown can be protected by ordinary means. It would, however, be practicable to run a neighbouring streamlet round a large rock-garden, concealing it here and there in shrubberies, &c., and letting it now and then meander through the grass

surrounding the site of the rock-garden. If the slugs, &c., within the streamlet were carefully removed, no recruits from beyond it could destroy our favourites. Where a stream does not run near the rockwork, the channel may be filled by means of a pipe laid on from the main pipe which supplies the garden proper. The outlet of this pipe may be very easily placed in a suitable part of the rockwork, in such a manner as to form a miniature cascade at no great distance from the channel which is kept filled by its waters. It is hardly necessary to add that the bottom and sides of the channel should be made perfectly water-tight with cement or well-puddled clay, &c.

SOIL.

The great majority of alpine plants thrive best in deep soil; in it they can root deeply, and once they are so rooted they will not suffer from drought, from which they would quickly perish if planted in the usual way; three feet deep is not too much for most species, and it is in nearly all cases a good plan to have plenty of broken sandstone or grit mixed with the soil. Any good free-loam, with plenty of sand, broken grit, &c., will be found to suit the great majority of alpine and dwarf herbaceous plants, from Pinks to Gromwells. But peat is required by some, as, for example, various small and brilliant rock plants like the Menziesias, Trillium, Cypridium, Spigelia marylandica, and a number of other mountain and bog plants. Hence, though the general mass may be of the soil above described, it will be desirable to have a few masses of peat here and there. This is better than forming all the ground of good loam and then digging holes in it for the reception of small masses of peat. The soil of one or two portions might also be chalky or calcareous, for the sake of plants that are known to thrive best on such formations, as the pretty Polygala calcaria, the Bee Orchis, Rhododendron Chamacistus, &c. Any other varieties of soil specially required by individual kinds can be given as they are planted.

(To be continued.)

LINES ON "THE ROSE SECRET."

In striking roses in a marmalade jar,
Max Klose's seems the simplest mode by far,
And the rose cottage, Chelford's grand display,
Will show his success at some future day.
Still there remains a secret to unfold
In striking roses quickly we are told;
But we now hope by the "jar" plan proposed,
The pent-up mystery is at last dis-Klosed.

—W. T.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Cianthus Dampieri.—This is now beautifully in bloom on an open wall about twelve miles south-east from London, the plant having stood the winter, with no other protection than that of an old light, and occasionally a mat during frost. A return hot-water pipe passes inside the foundation of the wall.—J. U. N.

The Poet's Narcissus.—Why not naturalise this lovely species in our wood-walks and in the wilder parts of our pleasure grounds? It is as easily grown as the common daffodil, and inferior to no denizen of the stony beauty. The roots are not dear; they may be planted any time after drying down till late in autumn, and indeed at any time, for daffodils may be moved without much injury when in full flower.

Wal. Plants.—The beauty which the wallflower now displays on many old ruined shores encourage many to try to develop much more floral beauty in such positions. That this is not only practicable, but easy, is fully shown in "Alpine Flowers." There is no doubt that with plants of the wallflower order alone, we could easily convert dreary old ruins, or parts of them, into lovely little gardens. The Arabis and all such plants would thrive on walls, though they would not attain such size as on the level ground. Even the Irises, which, at first sight, one would never think could grow on walls, have been seen to flourish there, a little root in as many may have seen on the Continent on old thatched roofs. There is no difficulty in establishing these lovely flowers.—H. V.

Spring Bedding.—The most effective beds which I have this season are two raised round ones, each nine feet in diameter. No. 1, has a centre plant and two rows of a white polyanthus, thickly studded with white single hyacinths; next, two rows of double red daisies, with red hyacinths, then two rows of *Arbutius grandiflora* purpurea and *Gentiana acaulis*, mixed with blue hyacinths, the whole edged with *Sempervivum californicum*. No. 2, has a centre plant of a double dahlia, with two rows of the two *Arbutius* and *Gentiana* and red hyacinths, the whole edged with *Echeveria secunda glauca*, planted out of pots in February. I have also a good third bed, which is likewise raised, and about twenty-seven feet in diameter. This has a vase in the centre containing *Yucca gloriosa* and variegated *Arabis*, from which radiate six rays or segments lined out with old plants of *Pyrethrum*: two of the divisions consist of dark wallflowers and white tulips; two others, single; two others consist of dark wallflowers and white tulips; two more contain mixed wallflowers and yellow tulips, the large intervening spaces being filled with *Mysotis dissitiflora* (seedlings), the whole edged with a broad broad margin of *Cerastium tomentosum*.—W. C.

THE SIX OF SPADES.

CHAPTER XIV.

Mr. Oldacre's Story—The Lady Alice.

MR. PRESIDENT AND FRIENDS, said Mr. Oldacre, you must " pity the sorrows of a poor old man, whose trembling limbs," and here he glanced complacently at his well-filled gaiters, " have borne him to your" excellent gin-and-water, and must not look for anything remarkable in pippins from a decaying and exhausted apple tree. As for lecturing you upon the culture of a garden, or haranguing you scientifically at all, I should no more think of it than of seeking horticultural information for myself in the books of those who wrote a century ago on the subject; and I have no shame in the conviction, that some to whom I now speak, beginning at a point where I have all but stopped, and having opportunities and resources, developed since my manhood waned, know more about gardening than I do. It is sufficient for me to have been in my day with the foremost, and to have fought my way to many victories. But were I to "shoulder my crutch and show how fields were won" to you of this generation, or to manipulate my "Brown Bess" as an old musketeer—to you who have such an improved artillery as leads one to expect that England will soon be able to pepper her enemies, however distant, from batteries fixed upon her shores—to you who are blessed with a thousand facilities unknown to your ancestors, of smashing and ripping up your fellow-creatures—how would you forbear to smile? No; as old Mr. Whippy, the huntsman—or rather the ex-huntsman, for he has been, as you know, a pensioner for years of my noble master's—trots after the hounds on his pony through the gaps and the gates, which he once despised, so must I now be content to look on from afar, travelling easily by quiet lanes and by-ways, and leaving the braver and the honours of the chase to you.

So I will tell you, if you please, a simple story—a mere incident, in fact—which occurred many years ago in the family I serve, but which made at the time a great excitement among us, and may still I hope prove interesting to you,

Through the solemn avenue of cedars which leads to our mausoleum, I have followed three dukes to the grave. The second of these at one period of his life was most austere and haughty. I may speak of his faults, although he is dead, because he lived to hate them, and to cast them from him; and I have no hesitation in enlarging upon them, as the circumstances of my story prompt. Well, then, he was just the proudest, coldest, most disagreeable duke that ever stalked ("stalk, to walk with high and superb steps," says Dr. Johnson) over the earth. It was a positive insult to the English language to call so much ungraciousness "your grace." We gardeners used to declare that the thermometers fell twenty degrees whenever he walked through the houses; and that the water froze in the tanks and cisterns. We were prepared to affirm that when he put on his coronet the strawberry leaves turned into ice-plants. Indeed, we all of us found a relief and comfort in this harmless kind of ridicule, just as schoolboys most delight to mimic the master who rules the most unkindly over them. It was a natural and pleasant rebound from the constraint and awful abasement to which his presence reduced us; and as for the propriety of our conduct, why, if men in high places are not high-minded, as they ought to be, they only become the more conspicuously assailable, and the homage which is offered to them is as unreal and worthless as the sham silver and the sham gold which the Chinese offer to their gods. So the duke played at being an idol, and we performed the worshipping. He thought himself something more than human, I am sure, and received our most lowly obsequies as though he were upon a golden throne. His demeanour was calculated to give us the idea that we had no claim, strictly speaking, to existence in any form, but that he tolerated us. He sent for us, kept us waiting for hours, and then either dismissed us without an interview, or gave us his orders as though he gave out oakum to convicts. In my subordinate capacity I was only honoured with two brief conversations, during which he was pleased to address me, for he never remembered names, as "Mr. Cutts" and "Rowbottom," appellations which belonged respectively

to the stud-groom and to an under-keeper, but which were as unlike Oldacre as, I dare say, he wished them to be.

We servants were not the only ones who shivered in his icy presence, and winked and capered with exuberant joy as soon as we were fairly out of it. Living at that time in one of the lodges, I frequently witnessed the arrival and departure of certain county families, who were annually distinguished by an invitation to the castle. To open the gate for these favoured guests, and to look upon their expression of complete despair, was like being hall-porter at a dentist's. They might have been blue-bottles, who had just set foot within the meshes of a spider's net, or rabbits, helplessly mesmerised by a weasel, and drawing nearer to their doom. One footman, I remember, was wont to weep in the rumble, and to assume for my edification such an aspect of pretended woe, pointing the while with his thumb to the unconscious tenantry of the chariot below, that at last I dared not go out to meet him, and he was compelled to dismount, and clear the way for himself.

But there was an entire change of performance, I can tell you, when these visitors came forth on their journey homeward; as distinct an alteration and improvement of countenance as may be observed in the features of that gentleman who appears from time to time in the pictorial advertisements, as now enduring the agonies of toothache, and now "Ha! ha! cured in an instant!" The tragedy, with its tyrant and dungeon-chains, was over; and, as the lamps blazed out once more, the orchestra, which had been executing Dead March and dirge underneath the darkened stage, emerged to play "Garryowen." They who had come to us so silently and sadly, laughed and sang as they drove down the park. They could not have been in a happier frame of mind if they had been poachers coming out of gaol in the shooting season. Hurrah! they were going home! home to have beer at dinner, and to turn to the fire at dessert! Home, to astonish the Browns, to fill the mouths of the Walkers with the waters of envy, and to awe the Bumbies with fancy statements about their "delightful visit at the castle." Well, I could bear truthful witness that the latter part of the proceeding had been delightful enough. As Robert Hall said to the pert young preacher, who asked what he thought of his sermon, "There was one very admirable passage—the passage from the pulpit to the vestry," so it might be affirmed with confidence that these guests had been especially happy in the last act and deed of—departure.

Now this iron duke, you will be surprised to hear, had actually condescended to marry. Of course, if Cupid had not been blindfold, he would no more have thought of taking aim at him than a schoolboy of shooting his favourite arrow against the wall of a fives-court, and how that promiscuous young archer made his dart to stick in the ducal granite must remain for ever among the "things not generally known." Never since Eve had the world seen such a proof of love's omnipotence, as when he sent our grim lord a-courting. No weaker influence ever could have taught that cold pale face to smile, to smile and to beam with a happy brightness, as the snow sparkles in the sun. But how he ever remembered her name, or brought himself to proffer those little tendernesses, which are usual upon these occasions—those touches of nature which make the whole world kin—is to me a complete perplexity, an unreality as astonishing as though I were to see the ghost of Hamlet's father with his arm round the waist of Jessica.

Poor Jessica! she came to us as joyous as a thrush in summer, and she sang awhile blithely and sweetly in the tomb of Hamlet's father. But when he resumed, as he shortly did, his old sepulchral ways, a chill struck the heart of our singing-bird, and all her mirthful music was changed into a plaint and wail. She had come from a home of love and cheerfulness, and she drooped in his arctic atmosphere, as an Orchid would droop in an ice-house.

"For a trouble weighed upon her,
And perplexed her night and morn,
With the burden of an honour,
Unto which she was not born."

Six years after her marriage-day, they bore her slowly through the dark avenue of cedars, and the chaplain came in his white surplice to welcome her with words of hope and peace.

Three children were born to them. The marquis, who soon showed himself to be a true "chip of the old (ice) block," and

a ghostling of amazing promise; Lord Evelyn and the Lady Alice, who, happily for us all, resembled their mother. Never were two brothers so unlike each other. I doubt whether the elder ever broke out of a walk or into a laugh in his life, whereas the younger would be scampering all over the place, with his little sister breathless behind, and his merry voice making our hearts glad. Now they were in the conservatory, changing the tallies, and sticking the fallen flowers of the Camellia upon the Euphorbia's thorns; now turning out a lot of sparrows, which they had caught in traps, and adorned with appendages of brilliant worsted, red, green, and yellow, in the immediate neighbourhood of the aviary, and so essaying to impose upon us the idea of a general escape and dispersion of all our feathered curiosities; and now "drawing" the shrubberies, with Lord Evelyn at one end as master of fox-hounds (the foxhounds by an Irish retriever), and Lady Alice at the other as an under-whip, waiting, watchful and silent, for the fox to break, which he generally did in the guise of a blackbird; and then announcing his exit with the promptest and shrillest of "tally-hos." Our marquis the while was indoors at his books, having, it was reported, a precocious relish for algebra, and an insight into the science of political economy not often to be found (thank Heaven) in young gentlemen of fourteen.

Years passed. There was some misunderstanding between the marquis and the Cambridge examiners on the subject of his being Senior Wrangler, and the duke, after hearing his son's statement, was pleased to pronounce that the Dons were "offal." Lord Evelyn went into the Guards, and I shall never forget him on his first return from London, after an absence of six months from the castle. I was at tea in the lodge when his mail-phæton drove up, and was hardly out of the porch, when his hearty "How are you, Oldacre?" drew my eyes to the handsomest, merriest, kindest face that ever wore a moustache. And sitting by him was a brother officer, just the man you would have expected that my lord would choose for his friend, looking as though he would go at anything from an ox-fence to a redan, and yet would do no wilful hurt, as though his heart, like Tom Bowling's, was brave and yet soft, and he was, in the full beauty of its meaning, a gentle man. I went back to my wife, who had Frank Chiswick's wife, a baby, on her knee, and I said to her, "Susan, my lord's come, and has brought home a husband for Lady Alice," "I'll believe it," she answered, "when I see his wings! for the duke must have something more than mortal to suit his fancy in son-in-laws."

And now, gentlemen, let the old horse catch his wind, if you please, dip his nose in the refreshing waters of the trough, and then trot on to the end of his journey.

S. R. H.

(To be continued.)

TEA CULTURE IN THE UNITED STATES.

In last week's issue (p. 538) you quote from *Hearth and Home* to the effect that "supposing" anyone one could get ten pickings of tea in a season, of 458 pounds per acre each, he would get a crop of 4,580 pounds. Undoubtedly, "supposing" it could be done, such a result would be in the highest degree satisfactory, but there is nothing whatever to warrant any such "supposition." The pickings gradually diminish in bulk as the season advances; the first flush of spring, if properly matured, being always the heaviest. An average yield of 450 pounds of made tea per acre per annum over any estate whatever, Indian, Javanese, Chinese, or Georgian, would be a very excellent and paying one. An average of less than this, rather than more, has been the experience of Indian and other planters, and should the Americans attempt the cultivation of tea (and there is no reason why they should not), it is to be profoundly hoped that they will not be led away by mere "suppositions" of which you have quoted a sample.

JAMES MACPHERSON, Erith, Kent.

NEW PATENTS, &c.

Lawn-mowers, parts applicable to other mechanical appliances for rotary motion in one direction only. September 12, 1871.—J. T. Griffin, Upper Thames Street, London. Lawn-mowers with a skeleton cast frame, on the spiral ribs of which steel cutters are fixed, the driving gearactuated by spheres between disc and a grooved lug wheel; the handle adjustable by clips on a bar, and the fixed blade adjustable with the leading wheels. The sphere and lug mechanism is applicable to other appliances, particularly ratchets, braces and cranes, for intermittent or continuous motion in one direction only.

THE INDOOR GARDEN.

THE LATTICE-LEAF PLANT.

This interesting Madagascar aquatic belongs to a genus containing some eight distinct species, six of which belong to India, and two, viz., *Ouvirandra fenestralis* and *O. Berneriiana*, to Madagascar. In its native country the leaves of *O. fenestralis* measure from ten inches to fifteen inches in length, and from two inches to three inches in breadth. In a young state they are of a pale yellowish green, which, as they advance in growth, changes to a deep olive green, and ultimately, before they decay, they assume a dark-brown hue. Of the structure of the leaves little need be said, as a glance at our illustration will at once explain that. When fully grown they resemble a piece of lace or lattice work, but when very young the openings to which they owe their peculiarity are filled up with cellular tissue, which as the leaves increase in growth disappears.

Of this singular water plant there is a good specimen at present in a tropical house in the Royal Gardens at Kew. This has no fewer than 173 leaves on it, the largest of which are $15\frac{1}{2}$ inches in length and $3\frac{1}{4}$ inches in breadth. This plant is growing in a tin pan, seven inches deep and fourteen inches in diameter, in a compost of fresh, turf, yellow loam, and a good admixture of silver sand. In the bottom of the pan a layer of crocks is laid, over which some of the roughest pieces of the loam are placed, and the remainder filled up with the compost from which the finest part had been separated. In potting, the soil is pressed rather firmly around the plant, and the whole is watered with tepid water through a fine rose, an operation which not only firmly settles the soil, but thoroughly cleanses the leaves. The last time this plant was potted

was in August 1870, but perhaps the beginning of April is a better time for performing this operation. On a side shelf in the warmest part of one of the stoves is a wooden tub fourteen inches deep and two feet six inches in diameter; in the bottom of this are placed an inch or two of cleanly washed pebbles, and the remainder is filled up with soft water.

In this the pan containing the plant is placed, the top of which when the tub is full of water is about six inches under the surface.

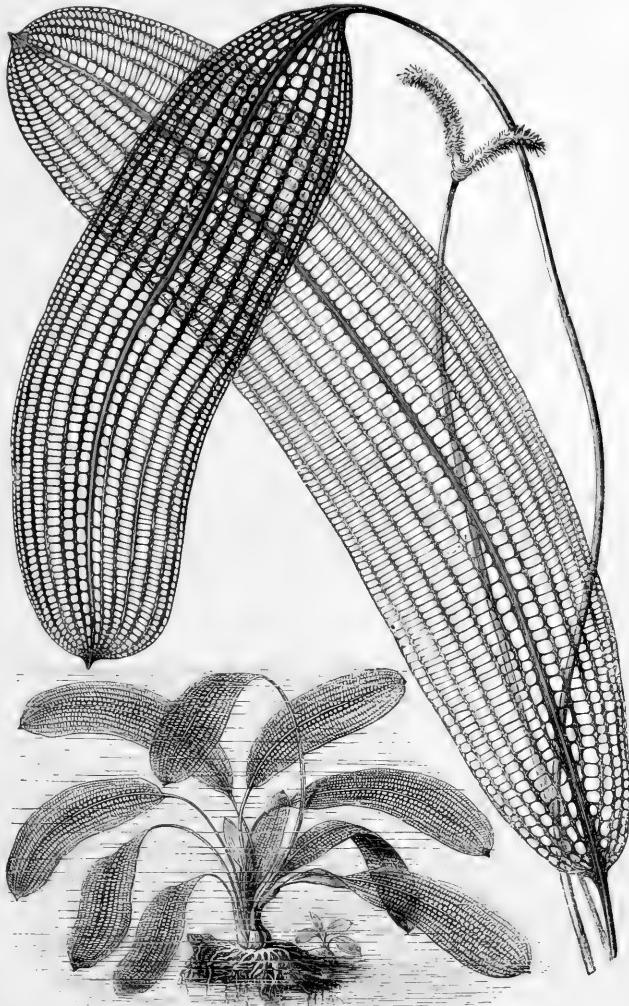

Some may think this too near the surface, but experience has proved that the plant succeeds very well at that depth. In shallow water the leaves float immediately below the surface, although in our illustration they would appear to be much deeper.

The temperature of the house in which it grows ranges during the winter months from 55° at night to 65° during the day, with sun heat, and this is increased as the days advance in length. An ordinary-sized pot of soft water is placed beside the heating pipes every evening, and the following morning its contents are emptied over the plant through a fine rose into the tub, which is kept level so as to admit of an equal overflow of the water on all sides. By this means the plant is not only benefited by the daily application of fresh water, but also by the speedy removal of any sediment likely to accumulate about the leaves. Confervæ sometimes prove troublesome to the lattice plant,

and some kinds of

water are more favourable for their production than others. Should their presence about the plants become apparent, they should be at once removed; the aquarium should be well washed with clean water; fresh gravel or pebbles ought to be introduced, and the plants should be watered rather forcibly overhead, and returned as soon as possible to their former quarters.

The flower spikes rise directly from the root to a few inches

The Lattice-Leaf Plant (*Ouvirandra fenestralis*)

above the water, and are separated at the apex into two, and sometimes more, divisions, which produce flowers of a whitish colour. Seeds from these flowers frequently ripen, and if sown immediately will produce young plants. From seed saved and sown at Kew in 1870, as many as fifty nice young plants have been raised. Young plants, too, come up thickly from self-sown seed on the surface of the soil around the parent and sometimes amongst the pebbles in the bottom. This I have seen often happen at Dalvey, in the north of Scotland, where the Ouvirandra is very successfully cultivated. The plants there are grown in an earthen pan in the warmest corner of an orchid house, and are treated exactly similar to the one at Kew. Young plants, however, require a higher temperature during the winter months than established ones.

Besides seeds, the Ouvirandra may be propagated by means of division of the roots which are very tenacious of life. Mr. Ellis, in his "Madagascar Revisited" (to which we are indebted for our illustration), tells us that it grows there "in places which are dry at certain seasons of the year, that the leaves then die down, but that the root buried in the mud retains its vitality, and when the water returns fresh leaves burst forth. Whenever the earth around even the smallest portion of it remains moist, that portion puts forth leaves when again covered with water."

The other species from Madagascar, *O. Berneriana*, requires deeper water than *O. fenestrata*. Its leaves, are not so open, and are from fifteen to twenty inches in length. It is, in short, altogether a coarser-growing plant than *O. fenestrata*.

MY INDOOR BRITISH FERNERY.

THREE years ago I had a lean-to house built, forty-three feet long, and twelve feet wide, one end of which (about fifteen feet) is shaded by the dwelling-house. On account of the want of sun I found that the plants did not thrive so well in the shaded end of the house as they did in the other.

Two years ago, being desirous of making a collection of British Ferns, I paid a visit to Devonshire, where I was fortunate enough to get some beautiful kinds, some account of which I have already given in your paper (see p. 376). When I came home I thought it was a pity to have such a number of nice Ferns and no place to plant them where they would be seen to advantage, I mean on rockwork, as I think Ferns do not look so well grown in any other way. So I made up my mind that I would partition off a portion of my lean-to house for my British Ferns, which I did.

The partition and door are of glass. Around the door I formed an arch of virgin cork, in which pockets were made and filled with Ferns, Echeverias, and Ivy. When you enter the door the highest part of the house is to your right hand, and the path next the wall. I intend to cover the wall this season with virgin cork, with pockets similar to that of the archway. As you enter on your left a raised bank runs along that side of the house, and across the end is a sloping bank, composed of drifts and boulders. The centre of the upper part of this bank sweeps in the form of a horseshoe, in the centre of which curve is an ornamental basin, four feet long, two feet wide, and two feet six inches deep; round the edge are Mosses, Grasses, and Ferns drooping down into the water. In the centre of the basin is a kind of rustic vase, in which is growing Selaginella denticulata, out of which rises an ornamental spray of water, which forms a pretty little fountain. I have here and there Sedums and Echeverias growing on the rockwork, which have a pretty effect amongst the Ferns. I intend to plant this season two good large plants of Tacsonia Van Volxemii, and train them on wires all over the roof, which will look very well I have no doubt.

This part of the house is not heated; but when the partition door is open (which it is all winter), the temperature is never lower than 50° or 55° in the day, and 45° at night, which keeps the Ferns green all the year round; but when the young fronds are coming up, I cut off the old ones, as they are liable to push the young fronds out of shape. The bank on which the rockwork is built is made of loam, leaf-mould, coarse sand, and a little peat. Now that the roots of my Ferns have got well into this mixture, they are throwing up young fronds very strongly. In winter I give the Ferns, &c., water now and then when the weather is mild; but, of course, they do not require very much, as it is not their growing season. In the spring I syringe them once a day, and now (May) I shall syringe them morning and evening. On fine days I leave the entrance door open from about nine in the morning till four in the afternoon, when I syringe and shut up for the night;

but in summer you can hardly give too much air and water over-head and at the roots of your plants. The path of my house is made of cement. I like it best for houses that are not supposed to be very ornamental; as after your house is syringed, if you run a few cans of water over it and brush it out, it always looks clean and fresh. When the Ferns and other rock plants are in full perfection in summer, and the little fountain playing, with gold fish darting about in the water, my Fernery looks very pretty. Any one who may have some house in which other kinds of plants will not grow well, or who may have some old neglected ones in the corner of their garden, may make a very pretty and effective British Fernery of it if they will only use a little taste and lay out a very small sum. Mine quite repays me for my trouble, time, and expense.

A. H., Upper Norwood.

A REVISION OF THE GENUS DRACENA.

BY DR. REGEI.

(Continued from page 517.)

DRACENA CONCINA (HORT. BEROL.).

STEM almost tree-like, simple, sometimes as much as two inches in diameter, clothed with leaves at the top; leaves sessile, recurved-patent, leathery, linear-lanceolate, from $1\frac{1}{2}$ to 3 inches broad, and from 2 to $2\frac{1}{2}$ feet long, with a stout midrib scarcely rising above the level of the upper surface but prominently convex beneath, folded longitudinally in a remarkable manner, striated with fine nerves and veins, and having a well-defined red margin; flowers unknown. Probably a native of tropical Africa.

Synonyms—*Dracena marginata* (Rgl.), *Dracena marginata*, var. *concinna* (C. Koch.), *Cordyline Betschleriana* (Göpp.), *Dracena Betschleriana* (C. Koch.).

DRACENA MARGINATA (LAM.).

Stem shrubby, branched, $\frac{1}{2}$ to $\frac{3}{4}$ of an inch in diameter, clothed with leaves entirely or down to the middle; leaves sessile, somewhat membranous, $\frac{1}{2}$ to $\frac{3}{4}$ of an inch broad, and 1 to $1\frac{1}{2}$ foot long, narrowly linear-lanceolate, gradually and for a great distance attenuated-acuminate, with a midrib which is visible enough on the upper surface and prominent underneath, traversed by a few longitudinal folds which are often scarcely visible, striated with fine nerves and veins, and with a well-defined red margin; flowers unknown. Madagascar.

Synonyms—*Dracena tessellata* (Willd.), *Dracena mauritiana* (Hort. Berol.).

DRACENA ENSIFOLIA (WALL.).

Stem tree-like, often branched, clothed with leaves entirely or down to the middle; leaves sessile, narrowly linear-lanceolate, not variegated, slightly undulated, with a midrib which is inconspicuous on the upper surface but prominent beneath, $\frac{1}{2}$ to $1\frac{1}{2}$ inch broad, and from $\frac{3}{4}$ to $1\frac{1}{2}$ foot long, concealing the internodes of the stem with their clasping bases; panicle terminal, simple, more or less recurved, with horizontally patent or recurved branches, on which the very fragrant white flowers are loosely dispersed in threes or fours, and accompanied with scarious obtuse bracts much shorter than the pedicels; tube shorter than the divisions of the corolla, which are about an inch long; style longer than the stamens. East Indies.

Synonyms—*Dracena fruticosa* (C. Koch.), *Dracena quiteensis* and *arborea* (Hort.), *Aletris cochinchinensis* (Hort.), *Cordyline ensifolia* (Fl. de Serres), *Dracena excelsa* (Ten.).

DRACENA BICOLOR (HOOK.).

A half-shrubby plant with a short simple stem leafy at the top. Leaves oval, slightly undulated, narrowed at the base into a short channelled stalk, abruptly and shortly acuminate at the point, with a thick midrib about $2\frac{1}{2}$ inches broad and 5 inches long. Raceme terminal with capitate branches, sub-globose, surrounded with bracts, and having the flowers closely set together. Flowers nearly sessile, each surrounded with lanceolate purple bracts as long as the tube of the corolla. Corolla white; tube cylindrical; divisions patent, oblong-linear, shorter than the tube and with a narrow red margin. Tropical Africa, near Fernando Po (Mann).

DRACENA JAVANICA (KUNTH).

Stem erect, shrubby, simple or branching; scales at the lower joints scarious, clasping, ultimately deciduous. Leaves oblong-

elliptical, slightly undulated, narrowed at the base into a channeled stalk about half-an-inch long, attenuated at the end into a recurved point or shortly acuminate, with a midrib scarcely rising above the surface, and traversed by very fine longitudinal veins from 1½ to 2 inches broad, and from 4 to 5 inches long. Panicle terminal, sessile, simple, with a few bracts at the base; branches patent or nearly horizontal, loosely racemose. Flowers from one to three together, on short stalks and with bracts about two lines long, shorter than the pedicels; corolla about an inch long; tube cylindrical; divisions oblong-linear, patent, about as long as the tube.

Synonyms—*Dracaena elliptica* (Hook.), *Sansevieria javanica* (Blume), *Cordyline Sieboldii* (Mig. fl. jav.), *Dracaena surculosa* (Hort. Berol.). Java and Sumatra.

A variety *Dracaena javanica maculata* has the leaves marked with white spots. Synonyms—*Dracaena elliptica*, var. *maculata* (Hook.), *D. maculata* (Roxbrg. fl. ind. and Kuth. enum.), *Cordyline maculata* (Fl. d. Serres, and Mig. fl. Jav.).

DRACENA TERNIFOLIA (ROXBURG.).

Scales at the lower joints of the stems herbaceous, patent. Leaves somewhat broadly elongated-lanceolate, lengthened acuminate, 2 to 3 inches broad, and from 8 to 12 inches long (including the stalk, which is from 1 to 3 inches long). Panicle with a stalk from 2 to 3 inches long; branches ascending. Flowers in threes, or, less frequently, in pairs, stalked. Bracts scarious, unequal, the inner ones short, the outer one about as long as, or longer than, the panicle. In other respects like the preceding species. I have seen dried specimens which had been gathered by Griffith, and which are described by Hooker in No. 5,880, *Bot. Mag.* Eastern Bengal.

Synonym—*Cordyline ternifolia* (Fl. d. Serres).

(To be continued.)

The following lines written by Douglas Jerrold in Miss Blanche Paxton's album refer to her being supported on one of the leaves of the Royal Water Lily (*Victoria regia*):—

On unbent leaf, in fairy guise,
Reflected on the water;
Beloved, admired by hearts and eyes,
Stands Annie, Paxton's daughter.

Accept a wish, my little maid,
Begotten by the minute;
That scene so fair may never fade,
You still the fairy in it.

That all your life, nor care nor grief
May load the winged hours
With weight to bend a lily's leaf,
And all around be flowers.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Pitcher Plants.—In shifting these care must be taken not to injure their roots. The pots into which they are to be put must be liberally and carefully crooked with a mixture of sand and peat moss, with a thin layer of sphagnum peat. Pot pretty firmly, and then give a good watering to settle all down. Afterwards shade, and keep the plants close in a warm moist atmosphere. They enjoy a brisk temperature and an abundant supply of humidity during their season of growth. In winter less warmth and less moisture will suffice; but even then the temperature of the house in which they are kept should never fall much below 60°.

Aubrietas in Pots.—About twelve months ago I got some cuttings of two very rare, and, to me, new *Aubrietas*; they were easily struck, and during the summer I had them in the open air. When autumn came I took a great advantage. I potted up a strong plant of each into twenty-four-sized pots shortly before Christmas, and left them for two months in a cold frame. About the middle of February I put them in a cool house, and by the end of the month they were in good bloom. From that time to this they have continued to flower without intermission, and the plants are now from twelve inches to fifteen inches through, and I expect them to continue blooming until the middle of May. W. D. C.

New Japan Primrose.—I find that this *Primrose* (*Primula japonica*) will flower easily in a cool greenhouse. I had three plants of it last autumn which were all kept moderately dry at the root during October and November. The leaves soon decayed, and the plants remained in an apparently lifeless state for six weeks. Soon after Christmas they were removed to the warmest part of a cool greenhouse, and well watered; the pots standing in pans, and constantly supplied with tepid water. They soon showed signs of new life, grew vigorously, and rewarded me with beautiful flowers. The first tier of blossoms is now beginning to decay, and I look forward for a good supply of early seed. This *Primrose* will doubtless become a great favourite for cut flowers.—W. WESTOE.

WHY is a man who can't learn by experience like a laurel? Because he is an evergreen.

GARDEN DESTROYERS.

BARK-BORING INSECTS.

(Continued from p. 548.)

THERE are one or two other points which are applicable to many of the bark-boring species as well as to the *Scolytus*, and which we may therefore dispose of in advance as generalities. One of these is the possibility of preventing their attacks, or curing the trees which have been attacked. Various plans have been propounded for this, but, so far as we know, they are all modifications of one idea, viz., to scrape off the bark where the tree is attacked, destroy the grubs and eggs in it, and to tar or paint over the exposed surface with some mixture injurious to the grubs but not to the tree. The most eminent professor of this method was M. Robert, who carried it out in a systematic way, and under whose directions, or according to whose recommendations, many trees, both in France and in this country, were treated a good many years ago. In the International Exhibition of 1862 he exhibited various specimens, showing his mode of operation, and others showing the result of it, so far as that could be shown in hand specimens. These consisted of portions of trees from which the bark had been removed, and which had healed up and were free from recent traces of galleries of bark-borers.

A more recent testimony to the efficacy of the plan was given the other day in one of our gardening periodicals (*Gardeners' Chronicle*, 1872, p. 78), in which the result of the treatment upon some trees in Regent's Park, after a lapse of nearly thirty years, was recorded. It was from the pen of Mr. Sowerby, the secretary of the Royal Botanic Gardens, and as it is a very fair specimen of the grounds on which success is often claimed for the method, we think it may be useful to quote it, and endeavour to estimate its relevancy and value. He says:—

"When the Botanic Society in 1839 entered on the ground in Regent's Park it was found to be encircled by a belt of elm trees, many of which were infested, and were being rapidly destroyed, by the larvae of the goat moth (*Cossus ligniperda*), and that more fatal pest, *Scolytus destructor*, a little beetle not larger than the common 'Death Watch.' This belt of elm trees was not included in the lease of the ground to the Society, but retained under the management of the Crown officers; however, in 1842, permission was granted to the Society to experiment upon the trees, with a view to prevent their total destruction; and so successful was the plan then adopted, that during the past twenty-three years only occasionally has an individual of either of the depredators made its appearance. One small tree, which by accident appears to have escaped attention and care, is quite dead, and fully illustrates the rapid and fatal work of the beetle. Although all the other trees in the belt are in robust health and vigour (for London), many of them exhibit full evidence of the scars and scrapings of our early operators."

At first sight this seems strong evidence in favour of the practice, but there are one or two inferences which may be drawn from it, which we think reduce its value. The allusion to the old scars and no new ones shows that the treatment has not been repeated. If it was it which got rid of them twenty-three years ago, it has not been it which has kept them away ever since. The beetle is abundant all round London, and if the trees had been in a fit state for its purposes we may be sure that the insect would soon have found its way back to them. It is the vigour of the trees which has kept them away, and that vigour cannot have in any way been due to the scarring twenty-three years ago. It is not pretended that that can add to the vigour of the tree. All that it professes to do is to take away an element which is destroying the vigour, and so allows the natural growth to be resumed. But we have already explained that it is only where that natural vigour is defective that the insect comes. It would therefore have continued defective here had not something else been done to restore it; and we imagine we are by no means assuming as a fact what is only a probability, when we take it for granted that the able managers of the Botanic Gardens, when exerting themselves twenty-three years ago to save the trees around the garden, would never limit their exertions to these scarifications

to get rid of the insect enemy. It would be an obvious libel upon their skill and judgment to suppose that they did not thin the trees, refresh the soil, and take every other known means to restore them to vigour; and if they did so we have them placed in the required condition for resisting and defeating the attacks of the Scolytus without the clearing process at all.

If this is the practical conclusion to which this experiment leads us, the theoretical examination of the principles involved in the treatment does not hold out a much better prospect of advantage from its employment. The weak part of the tree, indeed the only part of the tree that can be injured by the attacks of insects, is the living, growing part. The solid timber is not living; it is dead organic matter preserved from decay by the impervious enclosure of the living envelope, and may be eaten away by insects without any other damage to the life of the tree than the enfeebeling of the support by which it is maintained erect; so the bark is dead organic matter, which insects may consume, and sweep away without any other harm to the life of the tree than the exposure of the living envelope to the inclemency of the weather and external injury. The only living part of the tree is the cambium, lying between the bark and the wood, in which the formation of sap and the deposit of wood on the one hand, and bark on the other, is carried on, and which wraps up the whole tree from the minutest fibril of the roots to the extremity of the buds and leaves. This is the only thing that can be hurt by the attacks of insects, and it is only by consuming it that the Scolytus and other bark-boring insects bring about the deterioration and death of trees. Of course we do not mean to say that insects do not occasion damage by boring in the wood of trees, but the damage in that case is damage to the timber, not to the tree—to a product of the tree, not to the tree itself as a living entity. The position of the matter then is this—the Scolytus bores not only in the bark, an operation which is harmless or comparatively so, but in the cambium. M. Robert's process only touches the bark. If he were to remove the cambium, he would do the very mischief that the Scolytus is doing, only in a much more wholesale and destructive manner; and his effort is to remove all the bark where the insect is at work, and to expose, without breaking into the cambium, so that the grubs at work in it may be laid bare and open to the application of tar or any other mixture that may be preferred as fatal to animal life and harmless to vegetable life. We do not say that this cannot be done, but we do venture to say that it is an operation of great delicacy, and that there are ten chances to one that it will not be successfully done. Either too little of the bark will be removed, when the majority of the grubs will be left; or too much will be taken, when the cambium will be injured; and we need not remind our readers that if you girdle the tree—that is, break the continuity of the cambium all round—the tree dies. It is fair to add, however, that the plan has this advantage, that it is chiefly on the main stems and large limbs that the Scolytus settles itself; so that when these parts have been examined and treated, it will rarely be found necessary to go to the smaller branches, which would be an impossible labour.

All delicate and troublesome operations, however, are slow and costly, and this is no exception to the general rule. The expense attending this operation would be an absolute barrier to its general application, however sure its success might be. In any case, it can only be had recourse to for individual trees, which the owner has special reasons for preserving at any cost. Even for these, however, the plan is open to this great and, as it seems to us, fatal objection. The present crop of Scolyti removed, the general health of the tree is not thereby one whit amended; on the contrary, probably injured by the exposure and injury of the cambium in the process. Next year the tree continues in the same state of debility which invited the swarms of Scolytus last year; a fresh immigration takes place; again the trees are examined, and more of the bark removed; and still in the following year the same thing goes on, and we see no end to it until we have all the trees about standing shivering without their bark; and how long they would survive that we cannot tell, for no one, we suppose, has ever carried out the method to the bitter end.

The true remedy for the Scolytus is to improve the health of the tree. It may be that draining is needed, or that too much has been done, or that the soil is exhausted or bound about the roots. Every case must be examined on its own footing, and different modes of treatment will be necessary for different causes of mischief; but one remedy, which, for our own part, we would under no circumstances have recourse to, is M. Robert's method of scarifying the bark of the tree.

A. M.

NOTES AND QUESTIONS ON GARDEN DESTROYERS.

Grubs v. Ranunculus.—Search wherever the grubs destroying your Ranunculus appear or are suspected. Portions of carrot of last year's growth placed an inch below the surface between the rows at intervals, with a short stick indicating the spot where they are placed, will prove an attraction to grub and wire-worms; they must be taken up now and then, and the enemy captured and destroyed.

Early Appearance of Moths and Butterflies.—These have been out unusually early this year; but I thought it especially early to note on April 29th, perchance on a yellow wallflower, a fine specimen of the "Emperor," showing off its brilliant array to the best advantage. Particularly noteworthy, too, was a busy humming-bird moth gaily flying from flower to flower. Even much farther south I have seldom observed this moth until summer had been considerably advanced.—D.

Aphides.—We must prevent these getting a foothold on the trees, and be up and at them at once. There are many who lose all for want of promptitude. You see a few aphides, and look upon them as hardly worth attacking; they will wait till they may fight them in battalions. Such waiting means ruin. By keeping the trees as clean as possible, you may destroy a thousand or million in the germ. When they reach fullness the insect is dead. The shower of tobacco water then may slay its thousands, but it leaves but the wrecks of leaves and shoots behind it. Sprinkle the trees with tobacco water diluted with two or four parts water to one of tobacco, according to its strength.

Ants.—Being fond of roses, I have devoted a great part of my garden to choice sorts; but, to my dismay, ants have taken up their abode near the roots of some of my best standards and dwarfs; and not having forgotten the article in your paper, "Aphides and their Friends," I am all the more anxious to get rid of the pests as soon as possible. Can you help me? [Try sprinklings of powdered or granulated sugar over the plants; or lay dry distemper over them; sometimes they will build a city under an inverted flower-pot, in which case, city and all may be taken away on a shovel; or you may catch them in quantities on pieces of coarse sponge dipped in treacle water, visiting them often, and throwing the sponge into scalding water.]

Foof of Small Birds.—My crop of cherries is almost destroyed by birds. I have a greengage tree with almost every bunt picked out, and there is much havoc done to several other plums. I have been shooting small birds in my garden since last May, and, among them, in no case have I found anything resembling their crops except in the form of two spiders. Each had a caterpillar in its crop, but one of them also a dozen seeds to this caterpillar. I think this ought to be conclusive as to the evil that small birds are doing me. Almost all who take to gardening find out the injury small birds do. Two years' gardening convinced me that I could not have small birds and crops both in the same garden. Two years ago a neighbouring clergyman came to his living; he was then much in favour of small birds; now he wants to find a suitable means of destroying them.—M., in "Field."

THE NEW CEMETERY AT PHILADELPHIA.

The most creditable city improvements yet carried out by the Americans are their noble cemeteries. These are as great an advance upon ours as it is possible to conceive. They are in some cases as large as national parks, and as full of flowers and trees as a choice garden. Even small country villages have followed the example of the cities, and instead of the old-fashioned "God's Acre," where those who had been friends and neighbours in life were not separated in death, we see imitations of Greenwood, Laurel Hill, or Mount Auburn, with their drives, walks, and avenues; their select lots, railed in with stone and iron; their costly monuments, adorned with sculpture, and with other devices to rob the thought of death of somewhat of its gloom. In many respects the change is a beneficial one, especially in the matter of healthfulness.

Nevertheless, when, about thirty-five years ago, the idea of such cemeteries was broached, it encountered great opposition. This soon gave way, however; and now, as we have said, every large city, and almost every growing village, in America has its cemetery. Many of the leading cities, indeed, have more than one. There are half a dozen or more within driving distance of New York; and now Philadelphia has lately consecrated that of West Laurel Hill, in addition to the old Laurel Hill Cemetery, which is one of the finest cemeteries in the world, and occupies a beautiful and commanding site.

When at Philadelphia we examined these two cemeteries, accompanied by their founder, Mr. J. Jay Smith, of Philadelphia, who edited the last edition of Michaux's "North American Sylva," and were greatly surprised at their vast extent, and the

WEST LAUREL HILL CEMETERY, PHILADELPHIA.

beauty of the position they occupy on the high wooded slopes and hills on both sides of the river.

The new cemetery is situated at such a distance from the city as to preclude the danger of the ground being required for building purposes. It is likewise bounded on the east by the valley and river of the Schuylkill, and on its northern and southern sides by ravines so deep and precipitous as to insure that no engineering skill will ever pierce them with roads or streets. It consists of a delightfully undulating plateau, situated on a bluff projecting into the Schuylkill, thus constituting it a promontory bounded on three sides by the deep valleys already mentioned.

Our illustration, for which we are indebted to *Harper's Weekly*, is a view from one of the least elevated parts of Laurel Hill, looking towards the city of Philadelphia. We do not remember the size of this cemetery, but half a dozen Kensal Greens would not be missed out of it. Having visited the two Laurel Hills, we were somewhat surprised a few hours later to pass another very large and ornamental cemetery, namely, Mount Vernon, when on our way to see Mr. Buist, the well-known nurseryman of Philadelphia. Not the least interesting or admirable feature of these fine cemeteries, is the room allotted to each family and to each grave. Each family possesses a lot—quite a little garden, in which the graves are dotted about, and which is usually neatly kept and well planted.

THE FRUIT GARDEN.

NEW FRUITS.

POIRE DES PEINTRES.—A seedling of Louise Bonne de Printemps, grafts of which, worked in 1859, did not fruit until 1869. Tree tall, vigorous, and very productive. Fruit oval-pyriform, of medium or large size; at first of a grass-green colour, marked with numerous small red dots in lines at regular distances from each other; changing to a deep yellow, tinged with brilliant carmine on the side exposed to the sun. Flesh rather fine-grained, white, melting, juicy, sugary, and perfumed. Ripens about the end of August and in September, and should be gathered some time before it is fully ripe, and while the skin is green, otherwise it loses both in appearance and quality.

PYRUS SIMONII.—A new pear tree, named after M. Eugene Simon, who sent it ten years ago from China to the Museum in the Jardin des Plantes, with several others which have not yet fruited. Tree vigorous; leaves very deeply toothed (a character peculiar to all the Chinese pear trees yet introduced). Fruits nearly spherical, about two inches in diameter, on very short stalks, of a pale green, becoming yellowish when ripe, and marked all over with grey spots. Flesh yellowish white, brittle, sometimes melting, extremely juicy, acid, sugary, vinous, and with a peculiar aromatic flavour, somewhat like that of the quince or the Reinette Apple. The juice of this fruit is so abundant, and keeps its flavour so well, that it will probably make excellent perry. Ripens in September and does not keep long.

NORTH AND SOUTH.

OR THE BEST ASPECTS FOR FRUIT WALLS.

It has long been my opinion—and, as further experience has made me more acquainted with the quantity and continued supply required by most families in the present day, I am confirmed in that opinion—that, for the general purposes of early and late supply, the walls ought to face almost exclusively north and south. On one or the other of these may be brought to perfection every hardy fruit cultivated in this country, and, what is of more consequence, the season of most of them may be greatly extended. Indeed, in cases where families are not accustomed to retire to their country seats until the breaking up of Parliament or the approach of the shooting season, it is quite indispensable to have a good stretch of north walls, in order to be able to retard the ripening of some of the kinds; and aspect will affect this to a greater extent than many would suppose. I have observed that the difference in the time of ripening the same kinds on south and north aspects is often as much as three weeks; and the length of time which fruit will hang on, and keep fresh and plump, is much greater on the north wall. To enter into more practical detail, let us take cherries as an example, and I have no hesitation in stating that most kinds of cherries may be brought to great perfection on a north wall. They will crop there with more certainty, because the expansion of the bloom is

retarded, and they will ripen as well, with a perfectly good flavour; and therefore, bearing in mind the utility of a late supply, I would only plant a very few sorts on a south aspect, and all the rest on the north. I should thus have a certainty of prolonging the general season of these fruits greatly beyond the usual period. Again, the advantage of a north aspect for red and white currants is well known; but it may not be so generally known that the old Warrington gooseberry may be had in perfection from a north wall long after those in the open quarters are all gone.

Who that knows the wants of a large establishment can have too much south wall or south borders for early crops? or north walls and north borders for summer crops? And let me add that the other two aspects are of little comparative advantage with regard to the summer consumption, because they fill up no gap in the season which will not be filled to greater advantage by the northern and southern aspects. The best fruits for east and west walls, therefore, will be pears, which, being principally autumn and winter fruits, do not affect the general consumption. These considerations would seem to point to the great advantage to be derived from laying out our kitchen gardens in parallelograms rather than squares; so that, if a given space is to be enclosed, it will be better to have it in two or three long compartments, running from east to west, so as to give nearly all north and south walls. The spaces between these walls could be more easily worked, and to much greater profit, than large open squares. The flavour of some fruits from a north wall is in most seasons equal to that from other aspects; but, as many are disposed to doubt this, I will just state why I have come to that conclusion. The temperature of a north aspect is, on the year's average, far more equable than any other, and less liable to the extremes of heat and cold; this, then, is one reason why fruit trees may be supposed to crop and flourish well in the absence of the direct rays of the sun. And as for the flavour, provided the trees are not over-cropped, it is quite as good without sun as with it; nay, it is somewhat preferable, for I have often seen apricots and greengage plums on south aspects quite ripe on the side exposed to the sun, and green and hard on the opposite side; whereas, at the same time, I have found many fruits covered with leaves, and on which the sun's rays had never shone direct, perfectly and equally ripe, with a rather paler colour it is true, but with flavour quite equal to the best bits of the scorched ones. Does not even this show that direct sunlight is not absolutely necessary to ripening and flavour? In the case of cherries, from the May Duke to the most exquisitely flavoured Bigarreau, the flavour is perfectly equal to that obtained in any other aspect, if they are allowed to hang long enough on the trees.—John Cox, Redleaf, in "*Moore and Ayre's Magazine of Botany*."

PEACH TREES AND CHALK.

I HAVE never failed, during eight years in succession, to have excellent crops of Peaches on open walls, with no other protection than that of fine hexagon netting, and I feel sure that if any of your correspondents will follow the course of treatment which I pursue, they will be equally successful, without incurring the expense of glass protections. Even this season the leaves of my trees are large, clean, and healthy; fruit is plentiful, and the young wood all that could be desired. The netting, too, has lasted these eight years, and is good even now; little expense has, therefore, been incurred in that direction.

The treatment to which I subject my trees is as follows:—As soon as the fruit is gathered, I give them a thorough washing, and then the leaves so as to admit sun and air to the wood, with the view of getting it well ripened. About the middle of December I un nail all the young fruiting wood, and leave it loose until spring. As regards soil, I ought to state that I find Peach trees to be very fond of chalk; the best time to apply it is in November, when I carefully remove all soil for a distance of about six feet from the base of the trees, and lift all the roots with which I come in contact. In moving the trees I find five-tined forks to be best. When they are up, I get some fresh loam, and mix it with chalk, applying about four bushels of chalk to each tree, the roots of which are carefully spread out and covered with the mixture. Some very old trees here have been subjected to this treatment, and they are now in beautiful condition; their wood and fruit being all that I could desire.

In spring, when the blossoms begin to open—or rather to show colour—I commence pruning and nailing; operations which are not left till they are all in flower and covered with the hexagon netting. There are, I need scarcely say, various ways of pruning; but that which I have always worked on is what is called "Seymour's system," which consists in cutting out all old wood that has borne fruit, and nailing in the young base shoots. I never remove the

netting after it is put on till the leaves have so far advanced in growth as to protect the fruit. I disbud and thoroughly wash my trees with soft soap and sulphur, or use Gisburst Compound, in order to kill the aphis or red spider; the wall and crevices, as well as the trees being subjected to a thorough cleaning.

So successful, indeed, has my netting protection been, as well as my whole treatment, that I venture to recommend it to all who are desirous of having good crops of outdoor Peaches. I should add that I have the netting nailed tight, top and bottom.

High Grove, Watford.

G. BRUSH.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Strawberry Culture under Glass.—I have seen this season the best crops of this delicious fruit at Mr. John Westcott's market gardens, Topsham, Devon, that I ever before met with in my long experience. Mr. Westcott having made for years the Strawberry his special study, has succeeded in producing in the greatest abundance and perfection this fruit from February, when it comes on in the open ground, to late October. It is perfectly ripe to be eaten at any stage of plant in every stage of fruiting, the berries hanging as thickly as hops, of immeasurable size, perfect in colour, fine in flavour, and as solid as plums, fit to travel any distance when carefully packed. The varieties which he cultivates are the Goldfincher, Myatt's splendid Old British Queen, Princess of Wales, and a sort called the Refresher; the plants are not large, but strong and sturdy, with short stemmed foliage; some of them throwing up such masses of bloom-stalks as to resemble clusters of Elder flowers rather than Strawberry blossoms; every flower sets, and all the fruit in succession swells well. In short, Strawberry culture here is indeed a masterpiece.—JAMES BARNES.

Sun-spots and the Vine Crop.—As the connection of sun-spots with temperature and vegetation, especially the action of solaric emanations on the following facts may be of some interest. The years in which the vine crop in Germany was unusually good seem (in this century, at least) to have returned at regular intervals. The close coincidence of these years with the years of minimum sun-spots is shown by the following table:

Minimum of Sun-spots.	Wine-years.	Minimum of Sun-spots.	Wine-years.
1734 ⁸	1784	1833 ⁹	1834
1793 ⁵	(?)	1814 ⁰	1815
1816 ⁶	1811	1856.2	(?)
1823 ²	1824	1867 ²	1868

I may add that the gentleman who first remarked the regular recurrence of wine-years at intervals of about eleven years was not aware of the periodicity of the sun-spots, and could not therefore have been in any way prejudiced. The years given in the above table are the only ones known in Germany as good wine-years. These facts agree with the results of Messrs. Piazzi Smyth and Stone, who found that the mean temperature on the surface of the earth was subjected to a period of eleven years.—ARTHUR SCHUETER, OXFORD COLLEGE, MANCHESTER, IN "NATURE."

Pear Blight.—A correspondent of the *Albany Cultivator* suggests that those who wish to record observations on the cause of pear blight should state:—

- I. Character of soil, whether clay, loam, or sandy.
- II. Drainage, whether untrained.
- III. Surface, whether clay, gravel or slate.
- IV. Planting, deep or shallow.
- V. Cultivation, manures, &c.
- VI. Season, whether wet or dry, hot or cold.
- VII. Time of appearance of blight.
- VIII. Varieties suffering most.
- IX. Health of trees first attacked.

In recording the varieties of pears that succeed well or ill in each district or county in this country, it would also be well to notice these points, and also to mention the stock on which the trees are worked.

THE ARBORETUM.

THE BEARDED TREES OF TEXAS.

(*TILLANDSIA USNEOIDES*.)

One of the most striking features belonging to the forests of Texas that meets the traveller's eye, should he chance to arrive in that country in mid-winter, when the forests are disrobed of their summer beauty, is the long beard-like appearance which *Tillandsia usneoides* gives to the belts of trees and islands of timber, as the isolated clumps of forest are there termed; or those of the clearings, where some giant Oak or ponderous Magnolia, that have escaped the axe and fire of the settler, stand out boldly alone in the cotton and corn plantations, or by some freak of nature have been left standing solitary, or wildly dotted about the vast prairies. From the branches of these hang heavy masses of this *Tillandsia*, the grey hue and thread-like divisions of which give it the appearance of an old man's massive beard.

This *Tillandsia* not only attaches itself to the thick portions of the trees, but also to the most tender twigs, and clings with a tenacity that resists summer suns and winter blasts; beautiful to behold at both seasons, but more so in winter than at any other time of the year; for then it rocks backwards and forwards in obedience to the roar of the chill northers, as they sweep over the vast prairies, giving the

trees a wild, weird, and life-like appearance; or if undulating in the soft south breeze that often intervenes between the chill northers of the Texan winter, this beard-like *Tillandsia* gives to the noble monarchs of the forest the appearance of giant heads in calm repose. No one, indeed, could approach them in their winter form without a certain feeling of awe.

But in addition to giving a gaunt look to the Texan forests, and other arborescent vegetation of that country, this *Tillandsia* has yet other uses; it gives ample employment to settlers in their spare hours from the cotton and corn labour. They collect this *Tillandsia*, and throw it into heaps for a short time, to allow the outer cuticle to decompose; then it is dried in the sun, beaten, and cleaned of the outer skin, and the result is a fibrous material almost equal to horsehair for stuffing mattresses, or for other upholstery work. Large quantities of the prepared fibre are annually sent to the furniture makers of the Northern States; nevertheless, the collecting and exporting of this material has not yet assumed the magnitude and importance of cotton, although well-informed Texan authorities think that if the gathering and curing of it were carried out extensively and scientifically, it would be a more profitable business than even cotton-growing itself. This moss-like *Tillandsia* is eagerly sought after by the prairie cattle and horses, and is severely browsed down by them wherever it grows within their reach.

I am of opinion that this *Tillandsia* would grow in the open air in Devonshire, and in other milder parts of England, particularly if it were imported from Texas, where I have often seen ice a quarter of an inch in thickness. If brought from the West Indies, of which it is also a native, it might not succeed so well.

PETER WALLACE.

CONIFEROUS TREES IN CONNEMARA.

WHEN passing through a portion of the county of Galway during the early part of the past month (April), an opportunity was afforded for our seeing what progress some of the recently-introduced Conifers were making in that part of Ireland. The first place we visited was Moytura, the country residence of Sir William Wilde. It is at the head of Lough Corrib, near Cong, and close to the lake, and is much exposed to the westerly winds from the Atlantic. The kinds of pines which are usually selected for affording shelter in such situations have been planted in considerable quantities, and among them nearly all that are hardy of the Himalayan and Californian species. Those of the former which seemed to be thriving best were the Deodar, *Pinus Webbiana*, and *Abies Khotuv*, all of which were making good plants, and had the appearance of being well calculated for that part of the country. Of the Californian sorts, *Pinus nobilis* and *P. insignis* were thriving well, particularly the latter. *Thujopsis borealis* and *Thuja Craigiana* are also growing vigorously, and give promise to make fine trees after a few years; as do also the upright and spreading forms of *Cupressus Lambertiana*.

On the opposite side of the river is Cong domain, the residence of Sir Arthur Guinness, where some of the rarer kinds of Conifers have been planted, and are growing freely. There we saw some fine thriving plants of *Pinus insignis*, which grows well on the limestone soil of the county, and shows itself to be admirably suited for the west of Ireland. We had afterwards several opportunities of seeing it exposed to the severest storms which visit this island near the Killaries and at Kymore Castle, where it was making way well, and scarcely affected by the prevailing westerly winds direct from the sea. Where the Scotch Fir and *Pinus maritima* were planted near it, both suffered more than *P. insignis*, and neither was so healthy. It is evidently a hard struggle to get up wood in that treeless county, though some of the recent proprietors are making strenuous efforts to get the neighbourhood of their residences clothed with trees. At Kymore Castle, Mitchell Henry, Esq., M.P. for Galway, is sparing no expense to effect this object, and the trees which have been thickly planted are now sheltering each other and taking fine hold of the soil. It is, therefore, to be expected that after a few years this romantic and wild-looking part of the county will be greatly beautified by woods. Although the coarser and harder kinds of trees are those which have been planted in quantity, most of the rarer sorts also find a place there.

We have already stated that we saw *Pinus insignis* growing vigorously, and we may also mention *Pinus nobilis*. Nearly every species of Conifer which is considered to be hardy, or nearly so, is already to be found in the collection at Kymore Castle, which,

although yet small, may be looked on with no inconsiderable degree of interest, as the experiment now making there to get up those ornamental trees, will soon prove which kinds are best suited for being planted in that part of Ireland, either for shelter, profit, or ornament.

We may add that the gardens and conservatories at Kylmore Castle are something marvellous in their way in such a county, though they are still in their infancy; and will be well worthy of being specially noticed by some competent tourist after the works now in progress have been finished.

Mr. Armstrong, of Kylmore Lodge, has also been planting trees to a considerable extent, both in the mountain and near his residence on the shore of Kylmore Lake. In some instances they have failed twice, and he still perseveres, and has been making the vacancies good a third time. The growths which comparatively tender plants make in Connemara, show that it is not the cold which is the principal cause of trees being so difficult to establish there, as many plants which are cut down every winter on the east coast pass unscathed on the west. For example, at Kylmore Lodge and Lough Fee Lodge, the latter a fishing retreat of Sir William Wilde's, the Fuchsia is the plant used for hedge-making.

At Rynville House, the residence of Captain Blake, which stands on nearly the most westerly point of the Irish mainland, we saw a plant of *Fuchsia Ricartiana* fully sixteen feet high, with a stem about a foot in diameter, which has stood in the open ground there many years, and was flowering on the first day of April this year. *Escallonia macrantha* makes a magnificent plant there, where it flowers nearly the whole winter. The *Pernettyas* also grow very luxuriantly; and other plants which are natives of the Magellan quarter of South America all seem to thrive well in Connemara.

Dublin.

D. & Co.

EFFECTS OF FORESTS ON CLIMATE.

The following observations made in 1866, 1867, and 1868, by M. Mathieu, professor in the School of Forestry at Nancy, and reported by him in a paper read before the Congrès Agricole Libre, held at Nancy in June 1869, are interesting. Experiments were made upon the following points:—

1st. Does the wooded condition of a country exercise an influence upon the amount of rain it receives? The answer to this question was attempted by taking two stations at an equal height above the sea, but separated between fifteen and twenty miles, the one situated in a wooded, and the other in a cultivated country, and observing the rainfall. The result, reduced to inches, was as follows:—

	Agricultural Station.	Forest Station.	Difference.
8 Months, 1866	23·25 inches	27·24 inches	3·99 inches
8 " " 1867	33·93 "	36·41 "	2·48 "
8 " " 1868	21·84 "	29·49 "	7·64 "
Totals	82·02 inches	93·13 inches	11·11 inches

From which it appears that the most rain falls on the wooded country.

2nd. Does the covert of the forest, by intercepting the rain falling from the atmosphere, diminish to a considerable extent the amount of rain that reaches the ground? This was answered by placing rain-gauges beneath the trees and in the open ground, close at hand, and comparing results. Here they are:—

	Under the Trees.	In Open Ground.	Difference.
8 Months, 1866	25·90 inches	26·20 inches	.30 inches
8 " " 1867	34·17 "	36·41 "	2·24 "
8 " " 1868	27·67 "	29·49 "	1·81 "
Totals	87·74 inches	92·09 inches	4·35 inches

This shows that some part of the rain does not reach the ground. Nevertheless, as is shown by the following table, more rain reaches the earth sheltered by the forest than the earth lying in the open country:—

	Soil covered by Trees.	Soil bare of Trees.	Difference.
8 Months, 1866	25·90 inches	23·25 inches	2·65 inches
8 " " 1867	34·17 "	33·93 "	.24 "
8 " " 1868	27·67 "	24·84 "	2·83 "
Totals	87·74 inches	82·02 inches	5·72 inches

3rd. What effect does the wooded state of a country have upon the conservation of the moisture received by the soil? An answer

to this was sought in a comparison of the evaporation from two vessels, one placed in the forest, the other in the open ground. Evaporation went on five times as rapidly, taking the whole year into consideration, in the open air as in the forest, ranging from three to six times, between April and July; eighty-five per cent. of the rain falling in the open field evaporated, whilst only twenty-two of that falling in the forest was lost.

4th. What is the influence of forests upon temperature? The experiments in this direction had been conducted but a short time, but go to show that the mean annual temperature is lower in the woods than in the open country, and that the difference is least in winter and greatest in summer. In 1868 the mean temperature of the forest was lower than that of the open fields, by 4°.35 in the morning, and 9°.33 at night, in July; which difference fell in December to 0°.48 in the morning, and 0°.94 at night. Again, the average variation in temperature was much greater in the open country than under the cover of the forest between day and night. It ranged from 0°.05 to 8°.57 in the open air, but only from 0°.04 to 1°.22 in the forest.

THE PLANES.

BY GEORGE GORDON, A.L.S.

III.—THE CAUCASIAN PLANE (*PLATANUS DIGITATA*—GORDON).

This very distinct Plane is a native of the Taurian Caucasus, where, in the mountain valleys, it forms a stately tree fifty feet high, with a straight stem four feet in diameter; while on

Leaf of the Caucasian Plane.—Natural size, 6 inches long, including footstalk, and 6 inches broad.

Mount Caucasus and other high elevations it is never much larger or higher than a large bush or tree-like shrub.

The leaves are comparatively small, seldom exceeding six inches in length and the same in breadth; they are thick in texture, digitate, widest towards the base, slightly tapering at the footstalk, deeply divided into five open wedge-shaped, somewhat rounded lobes, which are more or less wavy and furnished with a pair of small side lobelets on the outer three, and a few large blunt serrations along the margins, terminated by small hard points; otherwise the edges are quite entire. The divisions between the principal lobes are very open, deep, and rounded at the bottom, and the adult leaves, with the exception of being slightly woolly in the axils of the principal veins on the under sides, are quite smooth and bright green; while the young ones are densely coated, particularly on the under side and margins, with a short white tomentum, which gives to them a frosted appearance when very young.

The balls, or seed heads, are very small, seldom exceeding half an inch in diameter; they are thickly furnished with bristly points, downy, and crowded together on the peduncles, generally in threes, but sometimes as many as six are produced on one footstalk. The stem of the tree is long and straight, with the principal branches rather rigid, more or less tortuous, and somewhat distantly placed, the lower ones being spreading, the upper ones ascending, and the shoots slender.

This Plane was first introduced by the late Messrs. Loddiges, of Hackney, about thirty years ago; and the largest trees of

Twig of the Caucasian Plane.

it in the neighbourhood of London, or perhaps in England, are those in the Victoria Park, which are now from twenty-five to thirty feet in height, although by no means in a favourable situation.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

MISSOURI SILVER LEAF, OR BUFFALO BERRY (SHEPHERDIA ARGENTEA).

This forms a striking and very elegant silvery-looking compact shrub of slow growth, but which, under favourable circumstances, will attain a height of from six to eight feet. It is a native of North America, particularly along the banks of the Mississippi and Missouri rivers and their tributary streams; is easily increased by the underground suckers, and grows well in any good garden soil that is not too dry. It was first introduced into this country in 1818.

The leaves are alternate or opposite, ovate or ovate-oblong, rounded at the ends, glabrous on both surfaces, greyish-green above, but quite silvery and dotted all over with rusty brown scales beneath; they are from one and a half to two inches long, and from one to one and a half inch broad, and are produced early

in the season. The shoots and lesser branches are of a deep rusty brown colour, and furnished at the base of each of the lower leaves with flower buds. The flowers, which are produced in April, are small, yellow, axillary, aggregate, and unisexual, or each sex upon a distinct plant. The female flowers are bell-shaped, equal, flat, and smaller than those of the males, and produced on short peduncles in racemes at the end of the branchlets, while the male ones are lateral, aggregate, and in groups that resemble a catkin. The berries, which ripen in September, are scarlet, transparent, acid, and about the size of the red currant, but richer in taste; they are much relished in America, where they form one continued cluster on every branch and twig of the plant, and are called Buffalo Berries and Rabbit Berries, and (by the American Indians) Beef Suet.

The *Shepherdia argentea* is well adapted for small gardens or the front of the shrubbery, but as the sexes are produced on different plants, it requires to have a plant of each sex placed near each other, or, what is better, so close as to form but one bush, or no fruit will be the result.

THE DOUBLE FLOWERING CHINESE CHERRY (CERASUS SERRULATA).

This cherry forms a very ornamental deciduous somewhat erect tree-like shrub from six to eight feet high, with stout branches sparsely furnished with laterals, which in April are thickly clothed with numerous clusters of large double flowers, that remain long in perfection; on account of this and its dwarf tree-like appearance, it is the most desirable of all the double flowered cherries for a small garden. It is a native of the north of China, where it is called "Young-To." It grows freely in any good garden soil, and is increased either by budding or grafting on the common cherry stock. It was first introduced into this country in 1822.

The leaves are obovate-pointed, quite smooth, bristly serrated on the edges, alternate on the young shoots, but more or less crowded together on the other parts, and very like those of the Bigarreau cherry, both in size and shape. The flowers are double, white at first, but afterwards, when fully expanded, tinged with red and produced in clusters on the previous year's growth.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Sciadopitys verticillata.—Can anyone inform me if this is quite hardy, and if not, to what extent? Also, what is the largest known specimen in this country?—DENDROPHILATOS.

The Big Trees of Australia.—I see that it has been frequently stated in your journal that specimens of *Eucalyptus* have been discovered in Australia which exceed in height the *Sequoia gigantea*. In what part of Australia have they been seen, and what is their specific name? where can I find full particulars respecting them?—DENDROPHILATOS.

Euonymus japonicus, or *Scaglia* shrub.—This glossy and handsome evergreen shrub is remarkably well at the sea-side forming large bushes. Such a locality, however, is by no means necessary for its perfect health, as it also thrives in dry and cold inland localities. Of all the many evergreens planted about Paris it seems to thrive the best. The variegated varieties seem to thrive almost as well as the normal dark-green form.

Cydonia japonica.—This, as we all know, is a brilliant wall plant. It is to its greater merits as an untrained shrub, isolated on the turf or grouped with any other low-growing annual shrubs, that I wish to call attention. I know nothing to prevent its growing in any part of the country where the spring sun sets all its branches on fire with glowing blossoms. After being once properly planted, it is better afterwards left alone, uncult, uncultured.—W. R.

Remarkable Yew Tree.—The largest yew that I ever saw is in a farmyard of a village (named, I think, Whitburn) near Frome. I cannot, however, give its dimensions, and it may possibly be the same tree as that alluded to by Mr. Berry, of Longleat. If Mr. Berry would furnish an account of Lord Bath's great beech tree, I think it would be interesting. I cannot describe the exact locality, as the qualities are unfeignedly formed by the junction of three times its size in timber, and is inside the park. As well as I can remember, the enormous spread that many specimens have, but the largest stem must contain an amount of timber, I should say, beyond that of any beech in the kingdom. In such an unprotected situation it is a wonder the tree escaped destruction in its infancy.—S. X.

Conifers in Boggy Soils.—I believe it is not generally known that many of the best conifers are quite at home in a well-drained bog, some growing with a luxuriance that cannot be met with in any other soil. I have many times felt surprised that people do not know the answer to the question "Can you plant in boggy soil?" is asked. Such land should be thoroughly drained, and then there are few plants or trees that will not thrive well in it. I have planted scores, from three to four tons in weight down to seedlings, and all are growing with freedom; but the *Cedrus Deodara* and *Wellingtonia* do not do so well as many others. *Cupressus macrocarpa*, *Lambertia*, *Grevilleana*, *Lawsoniana*; *Ritospora obtusa*, *pisiifera*, *squarrosa*; *Cephalotaxus drupacea* and *Fortunei*; *Thujopsis dolobrata*; *Thuja gigantea* and *occidentalis*; *Juniperus thurifera*, *virginiana*, *pendula*, *hibernica*, *chinensis*, &c., and, lastly, the much-abused *Cryptomeria* seem quite at home in bog; and the last named will grow, do what you will to it.—J. T.

THE PROPAGATOR.

ON PURE HYBRIDIZATION, OR CROSSING DISTINCT SPECIES OF PLANTS.

BY ISAAC ANDERSON-HENRY, ESQ., F.L.S.
(Concluded from p. 507.)

II. CROSSING WITH LONG STAMENS.

I HAVE made fewer experiments with the long stamens, but I have one before me now no less remarkable, perhaps, for its far-reaching result than any I have alluded to as done with the short stamens. It is a cross which I effected on the tall Rhododendron formosum, fertilized with a scarlet-flowered Indian Azalea, on the 11th June last. The seed-pod is finely developed, but I have taken care in this instance to avoid pulling it too early. And I may here notice, once for all, that to obtain the seeds of a cross—especially if it be extreme—sufficiently ripe, you must allow a longer time for it than for the ripening of the normal seeds on the same plant.

In all the foregoing crosses I had, perhaps, less an eye to accomplish a purely scientific experiment than to effect a beneficial result; for, after all, it is the *quid sit utile* which those for whom this paper is mainly intended will have most in view; and, in my estimation, science is best promoted when she is made to minister to some useful end.

The following experiment among the species of Clematis illustrates my view of sympathy as well as of antipathy, and I would add, of unnatural selection:—Having many years ago (long before, the Messrs. Jackman, who have accomplished such wonderful results) been myself working on the members of this genus, I thought of making another experiment on it, with a view to infuse a richer colour into a new and larger-flowering progeny; and, as I have observed already, I managed successfully to cross with pollen, kept for eleven months, the beautiful four-petalled Clematis Jackmanni on a thirteen-petalled flower of the fine C. candida. But it is of a cross on Messrs. Jackman's smaller, but no less beautiful, C. rubro-violacea I am now to speak. Though, like its congener C. Jackmanni, it sometimes comes with five or even six petals, it is in its general type a four-petalled flower. With a view to improve it in this feature, I crossed it also with pollen of the large-flowered Clematis candida, taken from a bloom having seventeen petals, though this clematis—a French hybrid, I believe, from C. lanuginosa—is in its normal state a six or eight-petalled flower. Though I crossed two flowers, after careful emasculation, I only gathered three seeds, but these all of unusually large dimensions. After the cross had taken, I left the normal blooms on the crossed plant to their fate; and though visited by insects innumerable, and though the native pollen was abundant, not one native seed, or any except the three produced by the cross, were ever formed on the plant; and the singular thing was that, with its own native pollen, abortive on itself, I unsuccessfully crossed the fine double white-flowered Chinese C. Fortunei; and a cross more prolific in the seeds it yielded I have not seen in the tribe before. I know not the parentage from whence this C. rubro-violacea was derived, though I believe it to be a mongrel with none of the Fortunei blood in it; yet mark how kindly the latter took with it—another instance of remarkable sympathy!—although I have no record of it, I think I failed to get C. rubro-violacea to reciprocate this cross.

In all these instances of sympathy and antipathy, and especially in this section of the natural order Ranunculaceæ, there is something apparently so inexplicable that I can only concur with what Darwin has observed in his paper on the existence of two forms in the genus Linum, where in summing up the good gained by the inevitable crossing of the dimorphic flowers, and numerous other analogous facts, he says, that these all lead to the conclusion that some "unknown law of nature is here dimly indicated to us." And this law, when discovered, may disclose more mysteries, tending, perhaps, to the wider divergence of species, with constitutions and habits better fitted for the climates and localities in which they may be cast, as well as for subserving the purposes they are intended to fulfil in the economy of nature. In looking at Ranunculaceæ, with their innumerable male and female organs (and the same thing occurs in the Myrtaceæ, most of the Rosaceæ, some of the Hypericaceæ, and in many other families and tribes), the idea was long ago suggested to me, that each separate row, from the outer to the inner circle of the stamens, might have some separate function, just as I believe that the long and short stamens have their separate functions; and with the view of testing the matter, I had last summer begun experiments with these outer and inner stamens; but other aims and objects interfering, I gave up the experiment after I had begun it on these Clematises.

But to make success certain, it is my custom, as I have already

stated, in crossing any of these polyandrous flowers, to take the entire bloom of one kind, and lightly to brush over, with all its anthers, the stigmas of the flower to be crossed, and leave nature to make her own selection. In referring to the Rubus tribe and its species, I am reminded of an intention I expressed in my former paper of perhaps returning to them afterwards. I again experimented upon them last summer. But though I tried various crosses among them, and reciprocated the cross, I had no success in any, except between the R. biflorus and the R. Idæus, and that only where I made the latter the seed-bearer. And to make sure of either event—success or failure—I had the R. Idæus early potted and put under glass, emasculating every bloom I meant to cross; and for more security I stripped off all other flowers—nay, more, I put the emasculated flowers under fine gauze bags, to ward off the invasion of insects. When ripe for crossing I removed the bag, and, on effecting the cross, I replaced it. In this way I succeeded in ripening three berries of the cross R. Idæus by R. biflorus, of which I sowed the seed between the 5th and 16th July, though as yet none have vegetated. But R. biflorus stubbornly rejected a reciprocal cross. Again I tried both of these on R. rupestris, and the latter on them; and though R. rupestris showed some sympathy with R. biflorus, in a slight tendency to form seeds, these came to nothing. In all these attempts I applied, as I have said, all the anthers of the male flower.

I cannot quit this part of the subject without offering some additional suggestions to those of you who wish to act on any hints I have it in my power to give:—

1st. If your desire be to hasten the flowering condition of plants—I recommend you to cross violently—i.e., where the allies are not too near akin, and above all, in the case of mongrels; for nature, ere she gives up, ever makes a violent effort to reproduce.

2nd. If you wish to make your hybrid flower more freely, as well as early, adopt the same advice.

3rd. By following it, you will find that you have attained a further advantage. Your plant will remain longer in bloom, because most mongrels, especially those among herbaceous or soft-wooded plants, to which these suggestions apply, are impotent to produce seed, or nearly so, and in such cases the blooms remain long upon the plant. I have another idea, not sufficiently tested, however, in reference to the first point among hard-wooded as well as soft-wooded plants, that all such as ripen their seeds more quickly than others (some among the rhododendron tribe ripen seed in half the time that others take) will reach more quickly their flowering state.

Lastly, as to fruits, on which, however, I have only partially tried my hand, I entertain the belief that we are on the eve of a revolution, and that by judicious and persevering crossing we may not only transfer the delicious aroma of one to another, and communicate harder and more abundant bearing habits to the hybrid progeny, but further, especially in stone fruits, such as peaches, plums, apricots, &c., we may, in addition to these advantages, increase the size of the fruits and diminish the size of the stones; and among vines, get rid of, or greatly diminish, the number of the seeds. And all this I hold to arise from that law of nature by which she not merely strains her efforts to reproduce (to which, however, she has assigned limit), but extends it when these have failed, to make provision for her creatures' want. These views gather strength from what has been already done; and I may especially allude to what Mr. Standish of Ascot has achieved among grapes, of whose extraordinary results an interesting account is given at p. 135 of the *Journal of the Royal Horticultural Society* for July 1866.

In conclusion, permit me to observe that, while my aim has been, in all the experiments I have brought before you, rather to achieve something useful and practical than to test the theories which Mr. Darwin and others—especially the Continental savans—have so much engrossed with, I cannot refrain from making some remark on the results and the conclusions which some of them have come to while prosecuting a series of crossing operations, namely, that such crosses do and must eventuate in sterility. M. Naudin seems, like Wichura, as already observed, to have limited his experiments chiefly to herbaceous or soft-wooded plants; and among such, especially among calceolarias, I too have often found myself brought to the terminus of bitter and hopeless sterility. I remember one instance where I had reached a perfect monster for size in that tribe, but except in that particular it had no other desirable property. Determined, however, to improve it by crossing, I found on trial I could make nothing of it, and on examination I found its stigma was a hollow tube, and that its anthers were hard masses, and contained not one particle of pollen. Man may run into such mistakes, but he cannot thence conclude that unviolated nature does so. Speaking from a general recollection, which does not admit of my specifying instances, I have often found among hybrid seedlings some of a vigour which, in that respect, were in advance of either

parent. May not such often occur in nature? and, as a naturally selected parent becomes the progenitor of a harder and more vigorous race (which having in it, according to Darwin's views, a tendency to diverge), may it not culminate in the long lapse of time into a distinct species, and even annihilate the weaker one which gave it being? So that, in nature's crossing, may not fertility and vigor take the place of sterility and weakness, into which she so generally dwindles when modified by man's device?

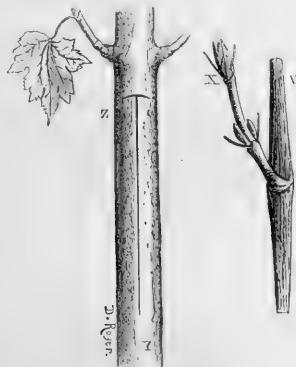

THE ART OF GRAFTING.

(Continued from page 467.)

SIDE-GRAFTING WITH A SIMPLE BRANCH.—This process is valuable for the restoration of defective trees, in supplying branches where they are wanting, and for grafting a new variety on aged subjects. It is equally of use in propagating plants. The woody scion will answer better for insertion under old bark, than the bud of the shield-graft commonly used. The scion in this case is a small branch, or a part of a branch, from four to eight inches long, having the lower part cut with a long splice-cut, the surface of which should be perfectly smooth, and cut thin to the bark at the point *b*. If it is desired to have a branch forming a wide angle with the stem of the stock, a bent or curved scion is selected; the convex part is cut and placed against the stock, while the top turned outwards will give the required inclination to the limb. With a perfectly straight scion one can contrive to have shoots on the side opposite the cutting, on the face which is united to the stock; this shoot, when developed, will form a branch almost perpendicular to the stem. In propagating certain trees, such as the beech, branched scions, two or three years old, are used, cut as we have described, with a splice cutting, rather thin towards the point.

The scion having been prepared, we make on the stock two incisions forming a *T* through the bark, not penetrating the albumen (*c*). The bark is then raised with the spatula, and the scion slipped under it, so that the top of the splice-cut may be on a level with the transverse incision in the stock. It is then bandaged, and the air excluded from the cuttings by the application of grafting-clay or wax. Instead of a *T* incision, we might employ a plain bull's-eye opening, into which the scion is slipped, or it would be equally easy to insert the scion under the bark by a sort of veneering.

GRAFTING WITH A BASED BRANCH.—We have recourse to this method for the propagation of some plants, more especially

Grafting with a Based Branch.

the variegated maple. The proper season for this is in August or September, with a dormant bud. A short branch (*x*) is selected for the scion. Anticipative branches are also serviceable. The little branch is detached with the grafting-knife from the branch on which it grows, but so as to preserve a strip of bark (*v*) above and below the insertion of the little

branch; the manner in which this is done has been already described. The woody fibres under the strip of bark (*v*) should not be removed; it would be dangerous to do so, and the surface should be merely smoothed down with the grafting-knife. On the stock (*x*) a *T*-shaped incision (*z*) is made, which goes no deeper than the bark, the lips of this are raised with the spatula and the heel (*v*) of the scion slipped under them. It is then bandaged with woolen thread or bast matting, like an ordinary shield bud or a short branch graft. It will be unnecessary to apply grafting-wax. In the restoration of fruit trees we have sometimes employed, under the name of scions, branches twenty inches long, with a heel four inches in length. By cutting off their leaves a week beforehand, and while they are still on the parent-tree, they are prepared for the separation. Covering them with grafting-clay as soon as they are grafted will prevent their drying up.—*C. Bulte.*

THE KITCHEN GARDEN.

THE CUCUMBER—ITS CULTIVATION AND USES.

(Continued from page 469.)

DUNG AND LEAVES.

WHEN good beech, oak, or other leaves, can be procured, they may be advantageously mixed with the dung. They will be found to moderate its temperature quickly, and sweeten it in about half the time that would be required to sweeten dung alone. There is also the advantage that leaves, though less violent in their fermenting qualities, are more continuous—that is, they heat less violently, but continue to give the heat for a longer time; consequently, a mixture of dung and leaves is preferable to dung alone. When used together, the mixing must be as complete as possible, and the mass just in the same state as to dryness as if dung alone were used. When hotbeds are made of leaves, it is advisable that they be gathered together in a dry state, be packed in an open shed to ferment a little, or be made into a stack, and be covered over with mats or some other material to keep them dry. In this way a gentle fermentation will soon set in, and then the leaves are in a fit state to make into a bed for plant growing. One advantage of leaves is, they do not attain a rank heat—neither, if used alone, do they give off injurious exhalations; consequently, for the purpose of forming a seed-bed, they are preferable to dung alone, and much less troublesome.

FORMING THE DUNG-BED.

In forming a hot bed it is always desirable to excavate the site, according to the nature of the subsoil, a foot or eighteen inches deep, to place in the bottom a layer of faggots or wood to form a 'dry bottom' for the dung to rest upon. The depth must be guided by the nature of the situation—if dry it may go two feet deep with advantage, but if wet one foot will be sufficient. The length and breadth must always be nine inches to a foot wider than the frame to be placed upon the bed when it is formed. In making the bed begin by shaking up the prepared dung, and place it in layers six inches thick, beating each layer firm with the fork as the work proceeds, and when we say firm we mean as compact as it is possible to make it. Some people tread the bed with the feet as the work proceeds, but that is not a good plan. A man with a fork, and not sparing of his labour, can make a bed as firm as it need be. Proceed in this manner until the bed is of sufficient height and for early forcing, say to begin in January, it should not be when completed less than $4\frac{1}{2}$ feet at the back and $3\frac{1}{2}$ feet in the front. For later work a foot less may be sufficient, but there is no economy in making a slight bed, as the heat quickly goes out of it. These remarks of course apply to beds whether they be formed of dung or leaves alone. The latter, however, are rather difficult to manage, that is, to get them to hold together, and hence it will be found necessary to form the sides with dung, just using as much as may be considered necessary to hold the leaves nicely together. When the bed is formed, place the frame upon it at once, put on the sashes, and shut it close down. In a few days it will begin to heat; but if it does not, cover the frame down with mats to induce fermentation. When it gets hot fork the bed over

daily until the steam evolved gets quite sweet, which will be when the face can be applied to the fresh opened sash without the olfactory nerves becoming disagreeably affected. In a word, the bed requires to become what is technically termed sweet, and free from ammoniacal exhalations. The sense of smell is scarcely to be trusted in such a matter, and therefore, before trusting plants in such an atmosphere, put in a cucumber plant or even a scarlet geranium for a night, and if it remains uninjured, that is if it is neither killed nor turned brown around the edges of the leaves, the bed is in a fit state to receive the plants. It may, however, so happen that the bed though quite sweet is in the centre part too hot to receive the soil without burning it. If such should be the case, then procure for the centre of each light a grass turf two feet square and two inches thick; around this six inches apart make holes in a slanting direction with a broom handle, and from a foot to eighteen inches deep. This will allow the extra heat to escape with freedom, so that the plants may be ridged out with the greatest possible safety.

Though we have formed the bed and prepared it ready to receive the soil and plants, it must be remarked this will not be sufficient to carry them through the season, and hence a stock of dung must always be kept in preparation, so as to apply linings directly the necessary heat in the bed begins to subside. Much, however, may be done to assist the bed by timely protection. Nothing tends so much to drive the heat out of a bed as cold piercing winds, and, therefore, for the purpose of protection thatched frames or hurdles should be in readiness to place on the windward side of the bed. Still, with all this, fresh linings will be required, and these must be placed back, front, or end, as the trial stick inside the frame may show where additional heat is most wanted. In adding a lining it is necessary that the dung be properly prepared, and care must be taken not to carry it above the woodwork of the frame, or injurious gases may get in and injure the plants. To keep them in proper order linings require to be turned, and partly renewed every fortnight, taking away the spent dung and adding fresh, but take care to keep them as sweet as possible. To protect it from cold winds and heavy rain a lining should be covered with straight straw and, that both back and front may be kept in place, by a framework, which will also act as a step to stand upon when regulating the plants. This frame may be made of deal or other scantling three inches square, the uprights being placed four feet, and the cross pieces to form the steps eighteen inches apart. Two steps will be sufficient. The uprights and steps may be what carpenters call "halved" together.

(To be continued.)

IMPROVED CUCUMBER BED.

I AM surprised that "A." speaking of dung frames for Cucumbers (see p. 469), should recommend solidly built up beds, when hollow bottomed ones are so far superior to them in every way, besides being capable of being put to other uses, so as to keep them at work the whole year round. The plan which we adopt is to build up corner piers of bricks to the required height, say about eighteen inches in front, and twenty-four inches at back, and to lay strong bearers lengthways on these piers and stout planks crossways on the bearers to form a floor, leaving sufficient apertures for the heat to pass through. We then set the frame on and put into it about three inches of leaf mould to keep down the steam; a lead of strong fresh dung is now put under the frame and enclosed with a lining of any sort of litter or garden refuse that may be at hand. In this way the heat will be up and the bed fit for planting in less than a week, thus effecting a great saving of time; and the heat may be regulated to a degree.

Frames set up in this way are useful all the year round for forcing asparagus, early potatoes, propagating bedding plants, for cucumbers and melons, and for growing young stock of stove plants during the summer, &c.

Having a good quantity of houses and pits heated by hot water, we, of course, get our earliest supply of cucumbers from that source. But for amateurs or gardeners with a small amount of glass these simple structures are invaluable. Any one giving them a trial will never go to the trouble of preparing manure for beds, as it is labour worse than lost, and in even the largest gardens it is not one of the gardener's troubles to find sufficient employment for all hands.

Henham, Suffolk.

JAMES GROOM.

HORSERADISH.

THE culture of Horseradish has of late been a good deal discussed in your columns; I have often thought I would relate my experience with regard to it; for as long as Englishmen can get a piece of roast beef for dinner they will always be pleased to have Horseradish along with it. Some fifty or sixty years ago Horseradish was generally to be found in old gardens; but it was not cultivated in the proper sense of the term; it was stuck in some out-of-the-way corner, among weeds and rubbish, and there left for generations. People were afraid to introduce it inside their gardens, on account of its rambling propensities; they thought, too, that if once introduced they would never get rid of it. To this must be attributed the fact of its being disdainfully placed in rough, out-of-the-way, useless kinds of spots, and looked at as an enemy, till roast beef-day came round, when it was sought after. Then the garden boy, whose place it was to serve the kitchen with vegetables, would grub or muddle out a piece of Horseradish, the trimmings and broken roots of which, left in the ground, served as a succession or future crop. Such was the plan on which Horseradish culture was in general conducted in those days—yes, and it is a fashion not yet quite extinct; of this I have had ocular demonstration, in places in which one would expect to find better order.

Market gardeners, it is true, even in those days, cultivated Horseradish to a large extent about Fulham, Battersea, Chelsea, Deptford, Rotherhithe, Bow, Bromley, and other places, on deep, rich, loose, open land, always trenching out the crop that had sometimes only been planted one year, and sometimes two years, when it was large and crisp, and replanting the ground again as the trenching proceeded.

For the latter purpose, such crowns as were crooked and short, and such as were not marketable, were used, putting them into the bottom of the trench, two feet or two feet six inches apart in rows, and one foot asunder in the row. Manure, compost, coal-ashes, or other refuse, was often tumbled in, first on, and then about, the roots and crowns, as they laid in a slanting position at the bottom of the last made ridged trench, for all the trenches were cast into ridges—thus the crowns were just between each ridge, and not deeply buried at first. Early in spring, after the roots had fairly started into growth, all was levelled down lightly, and a crop of radishes was sown on the surface; the latter being off by May, and when the Horseradish appeared in full row it was cleared off, and all kept hoed and clean until it could take care of itself, by covering the ground, and not allowing more intrusion on its part. Turnip radishes were the general surface crop.

What brought Horseradish into greatest notoriety was, however, the following circumstance.

Between fifty and sixty years ago in Gray's Inn Lane was a vast mountain, of years and years' accumulated London cinder-dust, filth, and garbage—yes, a real mountain of it; and amongst its vast and various accumulations were immense plants of Horseradish growing right up through the whole, the produce probably of crowns cast from sculleries to the dustbin. Here it found a favourable site; and as the mountain increased in size and height so did the Horseradish, with its great strength and spear-headed crown, continue to thrust itself through it. Enough at least did so to create astonishment in those days, and to bring the Horseradish into prominent notice; for when this mountain of refuse was removed, the immense length and size of the Horseradish roots were discovered. We had no horticultural journals in those days, but the *Times* and the few papers we had prominently adverted to this wonderful Horseradish, and related how, and where it grew. It was indeed a real phenomenon, the leaves being as large and thick as those of a banana, while its roots were as large and long as scaffold poles. How many hundredweight a root of it weighed it would be difficult to guess—yet one root, as large as a farmyard gatepost, was dug out, and exhibited. The publicity thus given to the matter, and the extraordinary perfection the roots attained in so rich a pasture, proved how simply Horseradish can be grown, and induced everybody to cultivate it if in earnest. Nothing would do after this but coal-ashes; and at coal-consuming places all over the country old accumulations of ashes were routed out and turned to account, while fresh ashes were saved for the future production of fine sized, well coloured, and crisp Horseradish. The modes of culture and the general treatment of this useful plant were various. Those who had a hoard of old cinder ashes planted Horseradish on the heap; others filled trenches with them, others mixed them with the soil in trenching; and another class made a deep hole in the ground with a crowbar and let down to the bottom of it a crown of Horseradish, filling up to the brim, as a matter of course, with coal-ashes. Indeed nothing was thought of then but coal-ashes for the future production of crisp, white, fine flavoured Horseradish, of a year or two's growth, instead of the yellow, tough, burning-hot whip-thongs they had always been

accustomed to; the produce, however, was as various as the soils on which it grew and the means by which it was brought forward. In short, success did not always attend this mode of culture; but to it must be attributed the first improvement in Horseradish-growing. One drawback in country-made coal-ashes was the deficiency of bones and other decomposed matters, in which London accumulations were rich. Bones, indeed, were then only looked upon as a nuisance, and great accumulations of them were either burnt or buried, only to be dug up again in after years, when their value had become known. I well remember the first bone collector I ever saw; people thought he was not quite right in his mind to take in hand such a detestable calling. At first he collected them with a basket and sack only; then he started a donkey and cart, afterwards a horse and cart; then he took premios, and, by persevering industry, started an immense bone-collecting business, ultimately amassing a large fortune.

JAMES BARNES.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

PRIVATE GARDENS.

Indoor Plant Department.—Conservatories are now gay with Calceolarias and Cinerarias, the blooming of which has been kept back until now. Roses, especially Maréchal Niel and Gloire de Dijon, are also in most places beautifully in flower; than these few kinds are better adapted for covering pillars or similar supports, particularly if planted out in borders. Many varieties of Heaths and several sorts of New Zealand plants are likewise now in perfection, and are kept in the coolest part of the house. Evergreen plants out of flower, and others making growth, are liberally syringed early in the afternoons, thus allowing time for their leaves to get dry before shutting up time. Cianthus, now out of bloom, are daily syringed, and, in cases where required, have their shoots thinned out a little. Passion-flowers, Hibbertias, Hardenbergias, Hæthomannuses, and similar plants, now at their best, are allowed to hang down gracefully, a position in which the foliage to some little extent protects the bloom from the fierce rays of the sun. In stoves, Caladiums, growing into good specimens, receive the support of a few stakes. Early Glinoxinas, now going out of bloom, are being succeeded by fresh plants, which, when growing, like plenty of water at the root, but not any overhead, a remark which also applies to Achimenes. Dracennas, Crotons, Marantas, &c., are now liberally watered overhead and at the root. Amongst Orchids various kinds of Aerides are now in bloom; also many Oncidiums, Odontoglossums, and Cattleyas, all of which are kept in a drier atmosphere than that in which they have been growing.

Pots and Frames.—Cinerarias are turned out of their pots, and planted in shady places, where they soon produce a number of suckers. A portion of these suckers is being potted singly into small pots, and placed in cold frames. Seedlings, as they require it, are also potted; as are likewise Primulas, three or four small pegs being put in around the crown to keep it upright and in its place. Half-hardy annuals are potted on as they advance in growth. Balsams, Cockscombs, Amaranthus, &c., are benefited by a little bottom heat, at the same time giving them air. Dahlia cuttings are still being put in, and young plants in pots are being gradually hardened off. Bedding plants in frames are now being exposed as much as possible to the weather; the sashes being replaced in the event of heavy rains or cold cutting winds. Pelargoniums beginning to flower in frames, are neatly staked and taken into the conservatory.

Flower Garden and Shrubbery.—May, both common and pink, Ghent Azaleas, Spiræas, Guelder Roses, and other shrubs, are now beautifully in flower; as are also double Pæonies, Iberises, Lithospermums, &c. Delphiniums, Lupinuses, Dianthus, Campanulas, &c., will also soon be in full beauty. Phloxes and Aster, throwing up too many shoots, have the weakest ones removed. A few remaining Hollyhocks are being planted; by making two or three plantings of these a longer succession of bloom is obtained. Bulbous plants, as soon as their leaves become withered, are taken up, and the offsets separated from the parent bulb, which is planted afresh. Narcissi, Jonquils, Tulips, and Hyacinths are being removed to make room for summer bedding plants. Perennials are being increased by means of cuttings of the young shoots inserted in warm borders, covered with hand-lights, and shaded from strong sunlight.

Indoor Fruit Department.—In late vineyards there is every appearance of a good crop. The vines are stopped a joint or so above each bunch, and the production of good, healthy foliage is encouraged. Vine borders are being mulched over with stable litter.

Figs are liberally watered at the roots and overhead, except in the case of those ripening, which are kept somewhat drier. Some early Melous are now ripening, and care is taken to prevent their experiencing sudden changes of temperature; the atmosphere is also kept a little drier than in the case of growing crops. Cucumbers are strictly attended to as regards thinning and stopping, but abundance of healthy foliage is always left. Fruiting plants are supplied with good soakings of weak manure water. Gourds are placed in cold frames, preparatory to their being planted out. Mushroom-houses are kept at as equal a temperature as possible.

Hardy Fruit and Kitchen Garden Department.—Stone fruits seem to have suffered considerably from the severity of the weather last month, but of Apples and Pears, especially late kinds, there will be no scarcity. Bush fruits are mostly set, and give promise of good crops. Thinning both shoots and fruits on walls is being performed. Fruit trees on walls are frequently syringed, and all curled or diseased leaves are picked off them. The surface of Asparagus beds is stirred occasionally, adding a sprinkling of salt. In the case of Artichokes a little soil is drawn to their roots. Nasturtiums, for salading and pickling, are being sown near fences, or treated in the same way as Peas; those sown earlier are being transplanted. Onions for salading are being sown, and also Lettuces for successive crops. Some late sorts of Broccoli are still being sown, and the earliest sown ones planted out. When it is necessary to hasten the "heating" of Cabbages they are tied up as Lettuces usually are. All growing crops have the soil about them frequently stirred, and a little soil drawn to their roots. Trenches are being taken out for Celery, and are well enriched with decomposed cow dung and rotten stable manure.

NURSERIES.

Now that the propagation of bedding plants is nearly over, more time and attention are given to other matters. Old roots of Dahlias are, however, still subjected to strong heat, and all shoots continue to be taken off as they appear, and are inserted in sand. These will hereafter be potted singly, and as they get a little established they will be planted out in light, rich sandy soil, where they will make fine tubers for next year's work. The finer varieties of Cineraria maritima, such as compacta, &c., many kinds of Coleuses, and other soft-wooded plants, are being rapidly increased. Hard-wooded plants, such as Heaths, Epacries, and others, are being struck, the points of young drawn shoots being selected for the purpose, and inserted in bottom heat under bell-glasses in small frames. Various kinds of succulents, such as Echeverias, and others, are being propagated by means of leaves, inserted in light sandy soil, or pure sand; long-leaved sorts are kept upright by means of small stakes, which also serve to keep them firmly in their places. The shorter leaves have merely their ends covered, and are permitted to lie almost flat on the surface of the pot. Plants of Primula japonica raised from seed in cold frames are being pricked off into pans, and the strongest simply into thumb pots.

MARKET GARDENS.

THE cold, wet weather which we have lately experienced, has obstructed the regular course of routine work under this head. Early plantations of Spinach are now nearly exhausted, and the ground occupied by them is being dug over, either to be planted with Lettuce or some of the Cabbage tribe, or else thrown into ridges for Celery. Early plantations of Cabbages are also now nearly all used up, and the ground is being treated similarly to that on which Spinach has been grown. Stumps for seed bearing, previously distinguished from the others by special marks, are now being lifted, in order to clear the ground, and are planted along the foot of walls or fences, or in any open place to spare, where they will be allowed to remain to perfect their seed. The weeding of the Onion crop sown broadcast is for the present discontinued until the weather settles a little, for no sooner do the narrow hoes perform their work, than the rains replant the uprooted weeds. Heavy dressings of manure are being carted on to vacant ground, which is being dug and held in readiness for other crops. Some weeks since, we observed that a line of Potatoes was planted, by means of a dibber, between rows of early Cabbages. The latter are now cut for market, the stumps removed, and the soil between the rows of Potatoes, which are now appearing above ground, is deeply loosened by means of long toothed hakes. Where it is practicable to protect French Beans, or at least a portion of them, from cold winds and rain, it is done, in order to promote earliness. This is done by placing mats in an upright position, fastened to strong stakes, on their windward side. Cucumbers and Vegetable Marrows are well protected with litter.

THE GARDEN IN THE HOUSE.

FORMS OF VASES FOR CERTAIN FLOWERS.

In compliance with the wish of your correspondent "D.T.F." (see p. 523), I will endeavour to lay down a few rules for the guidance of those (and they are unfortunately very numerous) who, as he remarks, have "very much overlooked this point in floral arrangements." Let me assume that the flowers to be grouped are to be seen by persons sitting round the table upon which the vases are placed. Let me further assume, for the moment, that all vases may be divided into three groups, (1) those with the receptacle for the flowers *below* the level of the eyes, (2) those with the receptacle *upon* a level with the eyes, and (3) those with the receptacle *above* the level of the eyes. Now take any flower you like into your hand for examination, and you will observe that you naturally hold it in that position in which you can best see and admire its beauty. If it be a Rose or a Camellia, you hold it below your eyes, that you may look down upon it and into it. If it be a Fuchsia or an Abutilon, you hold it up, you raise it as high as the brim of your hat at least, before you can fully appreciate its lovely form and colours. And so, I believe, that with every flower and every leaf there is some particular elevation and position at which you may derive the maximum of pleasure from looking at it. I need scarcely add, that having found this out, you have only to place it in a vase accordingly.

I do not mean to assert that there is only one elevation and position at which you can enjoy a view of any flower; on the contrary, many kinds which are at their best when much below, or much above, the level of the eyes, are also capable of affording much pleasure when placed about the eye-level; but I hold it as an invariable rule that the greater the departure from the position of maximum enjoyment, the less is the amount of ocular gratification.

W.

HARMONIES AND CONTRASTS IN FLOWER VASES.

People are too apt in arranging flowers to think only of what "will go well together," and to forget that pleasing effects may often be obtained by striking contrasts. There may be harmonies in form and harmonies in colour, there may be contrasts in form and contrasts in colour, and there may be harmonies of one and contrasts of the other; and I have never yet been able to make up my mind which of these combinations pleases me best. In a white trumpet-shaped vase before me are a tall piece of Solomon's Seal curving over to the left, a long branch of an Oncidium (I forget which) curving similarly to the right, a handsome spike, not quite straight, of Lupinus polyphyllus between the two, their bases being screened by a few fronds of ferns, from amongst which peeps out a flame-red bloom of an erect Gloxinia. Over the edge hangs a piece of Ivy, which twines round the stem of the vase. Let us examine the forms first. There is a harmony in the curve of the inflorescence of the Oncidium and the Polygonatum; but in all other comparisons, the forms are in contrast, especially in that of the blooms of the different flowers. In the colours, however, the harmonies and contrasts are more evenly divided. The yellow-coloured Oncidium contrasts with the blue Lupin and the crimson Gloxinia, and harmonizes with the light green foliage of the Polygonatum. The Gloxinia harmonizes with reddish-purple tints in some parts of the Lupin flowers, and contrasts both with the light green of Polygonatum and the dark green of the Ivy. On the whole, however, the contrasts are more numerous than the harmonies; and it is probably owing to this that the grouping exhibits a style and character which might not please every one, but which is at the same time bold, free, and unconventional. I wonder whether this arrangement would please "D.T.F.," who is so displeased with the higgledy mixtures of the present day, that he rushes off into the other extreme of "utmost simplicity," and puts only one kind of flower into each vase. This style is undoubtedly pretty, and very safe for beginners; but the effect of a dinner-table thus arranged will not bear comparison with that resulting from a judicious distribution of harmonies and contrasts in form and colour.

W. T.

COVENT GARDEN MARKET.—May 17th.

Flowers.—Bouquets have invariably some white flowers in their centres, sometimes a light coloured Tea Rose, at other times a Gardenia, or a cluster of Stephanotis blooms; around the centre are arranged sprays of Orchids, Lily of the Valley, White Azaleas, Bourvardias, Heliotropes, Pinks, Pelargoniums, &c., the whole interspersed with Ferns. The prevailing colour in bouquets is generally white, and none of them contain more than some half dozen different kinds of flowers. In some of them the dark blue flowers of Centaurea montana are very striking, and contrast admirably with the white. In addition to these we noticed cut blooms of Cacti, Philesia buxifolia, white and red Daturas, Cyclamens, still in fine condition, Sparaxis, Honeysuckle, Carnations, Ranunculus, Rhododendron Dalhousianum, with its large trumpet-shaped, cream-coloured blooms, grand examples of Anthurium Scherzerianum, and others. Besides these there was no lack of plants in pots, such as Heaths, Hydrangeas, Petunias, Variegated Grasses, suitable for the decoration of baskets, Amaryllis, Fuchsias, Pelargoniums, Calceolarias, &c., and hosts of spring-flowering and bedding plants.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

(MAY 15TH AND 16TH.)

This exhibition was held under a large tent on terraced grassy banks. It was principally conspicuous for its Roses, which were finer than those exhibited at any previous meeting this season. They were individually large in size, and were thickly studded with blooms of the finest quality, of which, the fully expanded ones on each plant would average over four dozen. One plant in particular, Souvenir d'un Ami, was furnished with at least six dozen expanded blooms. These collections of Roses were supported by large Bay trees, bushes of Box, Palms, Dracaenas, Yuccas, and similar plants at the back. Amongst hybrid perpetuums was Camille Bernard, a very dark double red; Victor Hybrider, a immense plant with splendid large rose-coloured flowers; Beauty of Waltham, in lovely condition; Vicomte Vigier, a rich dark coloured sort. Associated with these were also Edouard Morren, with immense reddish-pink flowers; Madame Victor Verdier, a brilliant deep red; Horace Vernet, a fine dark velvety flowered kind; Pierre Notting, one of the best dark-coloured kinds, and very double; Charles Lefebvre, also variety of great excellence; and Marquise de Castellane, with very large rose-coloured blooms. In addition to these we noticed La France, a grand rose, with finely formed pink blooms; also Charles Lawson, which we have seldom seen so nice; Princess Mary of Cambridge, in the form of a great pyramid of pink Roses; Mlle. Therese Levet, a particularly fine pink, and Marie Beauman, a brilliant red. Madame Villermoz was a complete mass of light-coloured blooms, and Catherine Mermet, also a Tea Rose, promises to take a prominent place among light pink flowers; of Celine Forester there was a grand specimen, covered with splendid very double yellow flowers. Cut blooms filled eleven large boxes; the varieties in which were arranged in three of each sort, and were very effective.

Of Succulents several first-rate collections were exhibited in competition for the prizes offered by Mr. Peacock; and that gentleman sent from his own garden at Hammersmith no fewer than fifty distinct species, including Agaves, Mammillarias, Melocactus, Echinocactus, and a few plants of Opuntias and Cereus. Of these, several from the manner in which they were grafted, appeared quite novel. Tall-growing Cereuses seemed to be the stocks most generally employed, and plants of these a foot high or so and from one to two inches in thickness, surmounted by a round head from four to six inches in diameter, had a truly singular appearance. Opuntias and others have been so successfully operated on in this way by Mr. Croucher, that he finds some of them do better than when

allowed to grow on their own roots. Amongst them were three plants of Echinopsis that had never before produced flowers in this country. These were E. Duvalii, on which were three open blooms of a lovely pink colour, each flower being about eight inches in length and nearly three inches across. In addition to this there was E. Wilkinsii, with flowers of a pretty rose colour, one being open, and two approaching that stage; and E. Rollandii, with blooms of a delicate violet rose; this was more spiny than the others.

The collections of Agaves staged for exhibition were of great interest, and comprised many new kinds. Bonapartia, Yuccas, &c., were also contributed. A dozen plants of Pilosocereus senilis, or "the Old Man Cactus," as it is commonly called, from Mr. J. Verschaffelt, attracted considerable attention. They were small, and densely covered with white hair several inches in length. Azaleas were not exhibited in the shape of large specimens, but a good collection of small plants came from Mr. Turner. These were associated with such plants as Pandanus, Palms, Dracaenas, Yuccas, Ficus, &c., tastefully arranged amongst them. A nice collection of Rhododendrons in small pots also added to the attractions of this show.

Amongst miscellaneous exhibitions were some valuable plants; in that from Mr. B. S. Williams, was a grand specimen of the variegated New Zealand Flax. We also noticed some fine Pelargoniums; various Minoulos, beautifully coloured; Carnations and Picotees of fine quality; Herbaceous Calceolarias, stocky in growth and well variegated as to colour; and one or two collections of hardy plants. Orchids were not plentiful. Amongst them were several fine varieties of Cattleya Mossiae; a beautiful specimen of Oncidium altissimum with twenty spikes of bloom; and a plant of Anderson's variety of Vanda teres, richly flowered; as was also Laelia majalis. This last came from Mr. Denning, who had, it was reported, kept it in a cool airy house during the summer, and in an intermediate one in winter. The same collection likewise contained the Odontoglossum coronarium, with pretty brown flowers, the lower lip of which is tipped with yellow, the whole having a polished appearance as if varnished. On one spike of a dried specimen of this plant, no fewer than seventy flowers have been counted. In addition to the above, there were also two plants of Masdevallia in bloom, one of which was new and unnamed. This is of a deep crimson colour, shaded with violet, and promises to be more than equal in point of beauty to any of this fine genus we as yet have in cultivation.

Fruit and Vegetables were but sparingly exhibited. There were, however, six Melons, all of one kind, named Little Heath, which were extremely well flavoured. Their united weights were forty-three pounds one ounce. There were likewise some well-ripened examples of Black one Hamburgh and Buckland Sweetwater Grapes, and also some splendid Early Gross Mignonne Peaches. Two fine examples of Cucumbers were likewise shown, named Maher's Prolific, but owing to its nearness to the kind called "Blue Crown," the committee did not award it a certificate. Besides these there were also some good new Peas grown indoors. They consisted of Carter's First Crop and Little Gem.

First-class certificates were awarded to the following, viz.:—To Azalea grandis, from Mr. Turner; to Odontoglossum coronarium, and to Masdevallia species, from Mr. Denning; to Agave Hystrix compacta, A. Leopoldi, A. robusta, and A. Kellschii, from Mr. J. Verschaffelt, Brussels; to Pelargonium Naomi and P. Chancellori from E. Foster, Esq.; to Gloriosa Ceclia, from Mr. D. S. Thomson; to Carnations, Empress of Germany, Princess Christian, and Marchioness of Westminster, from Mr. C. Turner, Slough; and to Melon, Little Heath, from Mr. J. Munro.

The exhibitions of Table Decorations opened up a field for a fine display of taste, and on this, as on former occasions, the designs simplest in construction and the least costly were the most successful. Some of the sweetest and loveliest flowers which our glass houses can produce, through bad arrangement in clumsy designs, were wholly ineffective combined with materials of even the most common-place description neatly arranged. Differences, indeed, as regards arrangement were more than usually apparent at this show, some of the exhibitors even going so far as to decorate their centre vases with the flags of all nations. Decorations in the tent set apart for tables for twenty persons were much more costly than those in the tent for decorations for twelve persons. The first prize table for twenty persons had one centre-piece, between which and the ends were flat vases, in which were two recumbent figures, and plants of Pteris tremula in pots let into the table; at one extreme end of the table was a dish about four inches high, on which was set a Pine Apple, and at the other end a similar dish with a Melon. The middle centre-piece had three tiers, one consisting of tin filled with sand, being on a level with the table; another, in the form of a small vase about half-way up, the top consisting of a long narrow vase. The ground-work of the base consisted of Selaginellas, several pieces of Adiantum farleyense, and Pteris serrulata being inserted in the sand and allowed to hang over on the cloth. Intermixed with these leaves were flowers of Philocactus, a few blooms of Rhodanthus Mangelsii, a flower or two of Gloriosa, a spray of Spirea japonica, one or two pieces of variegated Cyperus, and a few grasses. The middle tier of this vase was saucer-shaped; in this was also damp sand, in which were inserted a few pieces of Adiantum, sprays of Lily of the Valley, Rhodanthes, and grasses. The top vase was filled with water, in which were placed the sprays of Spiraea japonica and one or two other flowers, ferns, and grasses. The vases containing the recumbent small figures were flat, and decorated with Selaginella and fern fronds. The finger glasses consisted of saucers in which a little water was placed, and in the bottom three single leaves of tricolor Pelargoniums with a single double red flower laid on each leaf. In the centres of these stood the narrow finger glasses, properly so called, tastefully filled with a few sprays of fern, Spiraea japonica, Stephanotis, &c.

Where the base of the finger-glasses contained light flowers the top was composed of dark ones, and vice versa.

The fruits were merely placed on a vine leaf in suitable dishes, with perhaps a tiny frond of Adiantum run round the handle. The other prize tables were also very tastefully set off with elegant designs, and the floral display on that belonging to Mr. Webber exhibited much harmony and beauty of colour. The tables for twelve persons were equally tastefully got up. That to which the first prize was awarded was in reality the simplest of the whole, and was decorated wholly with hardy flowers with the exception of a few blooms of Pelargoniums and a spray or two of fern. The hardy flowers used in this class consisted of Myosotis, Pinks, Spireas, Fuchsias, Thalictrums, grasses, &c.

CRYSTAL PALACE HORTICULTURAL EXHIBITION. (MAY 11TH.)

ALTHOUGH compared with former years, this was a select rather than an extensive exhibition, yet it yielded to none of its predecessors in point of excellence. Azaleas, the chief feature of spring shows, were successfully contributed both by nurserymen and amateurs, and some of the specimens were of great size, and so closely set were some of them with flowers that the foliage was almost wholly concealed. One brilliant crimson-bloomed plant of A. Due de Nassau was particularly noticeable on account of its abundance of bloom; it was, however, equalled quite in beauty by a grand plant of A. magnifica, whose profusion of pure white blooms completely covered a surface some six feet high and ten or twelve feet in circumference. Besides these huge plants there were also good collections of smaller ones, among which, some of the newer sorts could be distinguished.

Among Roses in pots were some wonderful specimens well furnished with finely-formed large blooms. Indeed, this department was unusually well represented both by nurserymen and amateurs. In addition to plants shown in pots there were also several stands of cut Roses of different kinds, than which we do not remember ever having seen finer flowers.

Cape Heaths were wonderfully fine, consisting chiefly of plants of great size, some of them being as much as four feet in diameter. They were also well bloomed, although in some few instances the flower-buds had not yet expanded. In shape they varied from that of the compact Erica depressa to that of the erect, robust-growing E. Cavendishii. In these two kinds we have flowers of the purest yellow; in cassinidissima delicate white; in coccinea minor rose; and in ventricosa, superba, and others, flowers of deeper red. Two collections of Pelargoniums were admirable examples of high culture, their wonderful size exciting the admiration of everybody. Near the Pelargoniums was a collection of Herbaceous Calceolarias, excellent both in form and marking.

Orchids were perhaps not so abundant as might have been expected; but any defect visible in point of quantity, was more than counterbalanced in the way of quality. Amongst Oncidiums were fine plants of ampliflora majus, with bright yellow flowers; bifolium was also excellent; but the most remarkable, perhaps, of all, was a grand specimen of O. sarraceniae, with which everybody was delighted. Dendrobiums, which were also good, consisted of large examples of D. densiflorum, nobile, which has been in flower even since February, and several others equally striking. It is among Odontoglossums, however, that fine Orchids must be looked for; and anyone attempting to form a collection, however small, must not overlook the different members of this fine genus. There were likewise many others of great interest, such as Phalaenopsis grandiflora, Cypridiums, &c.

Specimen plants owing to their immense size and abundance of bloom, were objects of considerable attraction. Most noticeable amongst them were Mr. Baines's two magnificent examples of Sarracenas, to which we alluded a fortnight ago. There was likewise a plant of Gleichenia Splendens some four feet in diameter; and a huge specimen of Gymnogramma chrysophylla. Stachys purpurea was also remarkable, one plant measuring nearly four and a half feet through. In addition to these there were Theophrasta Imperialis, with as fine foliage as we ever remember to have seen on a plant of the kind; Allamandas, variegated Pine-apples, &c.; likewise grand specimens of Epacris, Tremandras, Dracophyllum gracile, with pretty white flowers, and some plants of Ixora coccinea with immense flower heads of brilliant red. Collections of new and rare plants were furnished by most of the leading nurserymen; but although they composed many of the novelties of the day, few occur among them that have not previously been noticed by us in reports of the different spring meetings; among them were the finer kinds of Ferns, Dracenas, Marantas, &c. A striking collection of hardy "foliage plants" which was shown was greatly admired. From the attention which these excited, it is evident that plants of this description must soon become favourites for outdoor decoration. Pansies were present in the form of cut blooms, and seldom do we remember having seen so fine a display; there were also good collections of Tulips, Ranunculus, Pyrethrums, and similar subjects.

EXHIBITIONS FOR THE CURRENT WEEK.—Royal Botanic Society, Regent's Park, Summer Exhibition, 22nd and 23rd instant; First Great Flower Show, Manchester Botanical and Horticultural Society, 17th to 24th instant; and Royal National Tulip Society Grand Horticultural Exhibition, Manchester, 25th; Sefton Park Great Horticultural Exhibition, Liverpool, 21st to 23rd.

Exhibition of Horticultural Buildings, &c., at Birmingham.—The following memorandum has just been issued by the Birmingham local committee:—"Prizes not having hitherto been offered in this division, the plan now submitted is, necessarily, to some extent experimental; but the sub-committee have very carefully considered the subject, and with respect to horticultural buildings, as they were not prepared to lay down, in the first instance, any special rules of classification, that will be deferred until the entries are completed. At that time the sub-committee will confer with gentlemen possessing scientific and practical knowledge of buildings, &c., who will be selected to act as judges, and who will then group this part of the collection in as complete a manner as possible before proceeding to make their awards. In addition to the medals mentioned in the first issue of this circular, the judges will have two extra gold medals placed at their disposal, one or both of which, at their discretion, may be awarded for horticultural buildings, as well as that first offered." We remind our readers that the last day for making entries is Saturday next, the 25th inst. Applications for entry forms should be made to Mr. B. A. Hallam, Midland Counties Herald Office, Birmingham.

Vitality of Roots.—Much has been said concerning the vitality which exists in seeds and bulbs, and we have many times given instances of it. Is the vital force which exists in stems and stalks, even herbaceous, of certain plants, known? I doubt it; and to show how much there is, I give the following instance. The 10th of last November I had a portion of the floor of my library raised to place a mantel-piece. The portion which was taken up was at a distance of three metres from the exterior walls, a part of which, facing the west, was constructed of a soft stone of Touraine, called bouldre. I lifted, with surprise, long herbaceous filaments (threads), totally white, covered at the nodes with rudiments of microscopic leaves and slender hairs. Their length was considerably, more than two yards. I recognised—but not without some difficulty—this plant to be the stalk of the field bindweed (*Convolvulus arvensis*). The wall outside had not been covered by the plant, and no root was to be found in the vicinity, which is a gravelly soil; nevertheless, the wall had been passed through, with all its thickness, by the stalks, of a similar whiteness, which came to find light in the warm part of the apartment, and climbed up behind my library. Others had run under the flooring, and there had vegetated, but the first which I gathered had its roots in the room. I questioned the mason. He told me that the flooring had been put down twelve years previously, and had never been disturbed since. Before that period the room had had a brick floor (or tiles) for more than a century. Thus, then, here are fragments of roots, buried there for more than twelve years at the least, and perhaps many more, in complete obscurity, without air, which now shoot up long and white every year, two or three metres in each direction, without appearing in the least exhausted. Others have had sufficient strength to pass between the joints of the stones, heedless of the mortar, and come to find heat and warmth in the room.—*Ed. André, in "L'Illustration Horticole."*

ANSWERS TO CORRESPONDENTS.

A. D. (1. *Adiantum concinnum latum*; 2. *A. macrophyllum*; 3. *A. trapeziforme*).—R. SAUNDERS (Guano water, if not applied in too strong doses, is of great advantage to cucumbers in pots).—S. S. (The grub to which you refer is uncommon; instances are on record of its attacking rose trees during the night, and eating off their shoots. Search for it during the day in the earth, in which it buries itself. Can you send us a specimen of it?).—C. J. S. (The plants of Marchal Niel to which you refer are planted out in a bed inside the house; some are budded on briars, others are on their own roots).

THE GARDEN can be had in neatly covered monthly parts.—On sale at Messrs. Smith & Son's bookstalls, and may be had through all booksellers. Part V., for April, now ready, price 1s. 5d. Publishing Office, 37, Southampton Street, Covent Garden, London, W.C.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

Readers who may find it difficult to procure **THE GARDEN** regularly through the newsagents, may have the numbers sent direct from the office, at 19s. 6d. per annum 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsagents at the railway book-stalls, and from the office.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

SCIENCE, THEORY, AND PRACTICE.

MR. NEWMAN'S allusion to "practical men," in a recent number of *THE GARDEN*, touches upon a subject of the greatest importance to horticulture and to many other branches of human knowledge. Yet so far as we know it has not been discussed in any periodical devoted to horticulture. We allude to the misuse of the above terms in our literature and in our everyday talk. As Mr. Newman remarks, the gardener does not regard the entomologist as "a practical man." But how do the entomologist and the botanist look upon the gardener? Why, they may, or may not, call him a "practical man," but they will certainly say he is "not a scientific" one. Let one of our most intelligent gardeners, or amateurs, or nurserymen, write a book embodying the results of twenty years' experience and observation, and the probabilities are that he will, as a matter of course, find it alluded to as "not a scientific book," while perhaps it is highly praised for the original and useful knowledge it embodies. The reviewer is probably a gentleman who has mastered the technicalities of botanical language, and perhaps applied them to some local flora or elementary class book of botany. Upon the strength of these accomplishments, comparatively trivial as they are known to be, he presumes to place himself in a group supposed to be entirely distinct from the gardener, nurseryman, and amateur, and calls himself a "scientific man." The object of this article is to point out how much we lose by the wrongful use of words, and how greatly we impede progress, both in horticulture and botany, by using false distinctions as to knowledge and the means of adding to it.

It should be clearly understood by all men that all knowledge is the same in kind; that there is no real difference between "science" and practice, and that what is sound in theory must be sound also in practice, and *vice versa*. There is no real difference. The old meaning of the word science is knowledge; the modern meaning is the same. It has been shown over and over again by eminent men that the methods of investigation applied to the most difficult problems that have yet engaged the attention of man, differ in no essential respect from those used by the humblest observant gardener. What is true scientifically, must be true also in practice. Such an expression as, "It is right enough in theory, but wrong in practice," is simply nonsense. Nothing can be "right in theory and wrong in practice." "It is mere theory," is often the silly comment on some simple statement, the truth of which could be thoroughly tested by direct experiment in the garden. To say that the author of a proposition "is not a practical man," or not a "scientific" one, instead of investigating it, is an easy-but ungenerous and unworthy way of saving ourselves the trouble of trying whether he is right or wrong.

Who is to blame for this state of things? Chiefly the class of botanists and "scientific" men who do not rise higher in the study of the vegetable kingdom than the stage of mere technicalities and their application. We might suppose that the Royal Horticultural Society would not propagate errors of this kind. But this is precisely what it does, and at the great Birmingham meeting there is to be a scientific and a practical congress. Addresses are also to be given on separate days on "recent progress in scientific," and "recent progress in practical" horticulture, as if these terms did not mean one and the same thing. Thus a society for the encouragement of gardening says, in effect, to gardeners:—Your labours and

observations have nothing to do with science (knowledge), and we will take care that there is no mingling of such different classes. Your practical notions are of some slight account; we will devote a day to them as soon as we have completed our scientific labours. And thus the most miserable of class distinctions is maintained by the very body whose true work it should be to counteract the effects of a use of language false in itself and really hurtful in its effects on horticulture.

One of the first things done by our greatest thinkers, in clearing the ground for the study of the highest philosophical problems, is to prove the identity in kind of the ordinary and the "scientific" methods of observation, and the ONENESS, so to speak, of theory and practice. It may be urged by the botanist that his knowledge is capable of more accurate demonstration than the gardener's; but this is not the case, except as regards descriptions of plants. Such a book, for example, as Lindley's "Theory of Horticulture" would be called a scientific book, while one of Loudon's might not be considered worthy of that distinction. Yet it has been demonstrated that "The Theory of Horticulture" embodies many erroneous propositions, and more important errors than will probably ever find their way into a gardening book. The object of this article is not in any sense to attempt to undervalue the labours of the botanist or of any other worker in the cause of knowledge, but simply to plead for a better understanding than now exists between classes of men that are really working in the same cause and with the same tools.

Let, then, no lover of gardening or of knowledge concern himself whether things are described as scientific or practical. Our business is, in whatever statements concern horticulture, to ascertain whether they are true or false. Let us describe books or articles relating to our art as profound or elementary, lucid or obscure, learned or the reverse, right or wrong—there are plenty of true and understandable words and distinctions; but do not let us despoil our fair garden ground by bolstering up in it such obstructive and unnatural barriers as those above pointed out.

W. R.

NOTES OF THE WEEK.

— The wintry weather we have experienced throughout May has considerably retarded the Rhododendrons, but they are now opening in great beauty in the London parks.

— In consequence of the severity of the weather there is as yet scarce any of the summer occupants of the flower beds planted out in the London parks. The great lines of beds along Park Lane are yet brown and naked.

— MR. J. ORCHARD HALLIWELL, having, says the *Architect*, purchased the entire area supposed to be occupied by Shakespeare's garden, Stratford-on-Avon, intends to present it to the town. All houses built on it will be removed.

— It may be laid down as a rule, says the *Scientific American*, that a larger proportion of white flowers are fragrant than those of any other colour; yellow comes next, then red, and lastly blue, after which, and in the same order, may be reckoned violet, green, orange, and black.

— THE vintage on three of the vineyards on the Barrabool Hills, says the *Australasian*, has commenced, but owing to the oidiun which has this year affected the vines, the yield is not expected to be more than half that of last year. The Black Prince variety has more particularly suffered from this cause.

— ON the 13th instant an Act received the Royal assent to amend the Public Parks (Ireland) Act, 1869. Doubts have arisen as to whether the parks, which the governing bodies of towns were authorised to establish and maintain, must be situate within the boundaries of the towns. Parks may now be maintained within or without the boundaries of the towns. Power is given to sell superfluous land.

— SINCE our last issue the weather has been most unfortunate for plants. In the Midlands, in some low-lying districts, the effect of the frost of Saturday night the 18th, was most disastrous. The hardiest plants and trees suffered severely. The young shoots of the Norway spruce were every one killed. Hardy British ferns, the budding leaves of the hardiest forest trees, and roses are among the things scorched almost to the quick; even the golden flowers of our British Globe-flower were blackened. A fine mass of the Prostrate Gromwell (*Lithospermum prostratum*) in Mr. Vertegan's nursery, at

Birmingham, on the 18th a sheet of gentian-like blue, had, on the 19th, every flower drooping and dead. It would require a long list to enumerate all the disasters.

— THE NEAR ends of the Row and Drive in Hyde Park are just now quite fragrant with the breath of Stocks and Mignonette, arising from masses of these plants. The planting of these is a step in the right direction. Apart from the intrinsic merit of the plants as used here, they fill a great blank between the early and the summer flowers.

— ALL interested in spring bedding plants who have an opportunity of seeing the display in the Lower Grounds, Aston, near Birmingham, should not fail to do so. Anything more brilliant could not be seen, even in the summer flower garden; the weather has somewhat retarded the display, so that it will remain in good condition for a considerable time to come. Nearly 16,000 persons visited these grounds on Whit-Monday.

— THE dingy old shed in which the flower department of Covent Garden Market has been carried on for some years has been pulled down, together with three houses in Wellington Street. Several thousand tons of earth have been excavated, massive groined arches have been constructed, and an iron and glass floral hall reared on the top of them. It is fifty-four feet high in the centre, and when finished will cover an area of 16,000 superficial feet.

— RAPID progress is being made with the preparation of the show ground of the Royal Horticultural Society at the Lower Grounds, Birmingham. The large tent is complete all but the covering, and seems suitably designed, but appeared to us too small, and its scheme of walks too complicated for the large numbers of persons that may be expected to visit the show. The plants in the main tent will be arranged on tiered steps, somewhat like those at the International Exhibition of 1862 at South Kensington, but lower.

— At a late meeting of the Metropolitan Board of Works a resolution was passed (including a previous resolution) by which some acres of land near Southwark and Finsbury parks are to be thrown into those parks. The public are indebted for this concession to the renewed interest taken in questions of metropolitan administration. Hampstead Heath and the lands round Victoria Park, have also been saved from the builder; and there can be no doubt that a little vigilance will save Epping Forest.

— THE usual "flower sermon" was preached, according to custom for these last twenty years, on Whit-Tuesday evening, at the church of St. Katherine Cree, Leadenhall Street, by the Rev. Dr. Whittemore. Each young person brought a bouquet, and the fine old church brightened wonderfully under the influence of beaming faces and gay flowers. Service commenced at seven o'clock, but long before that hour the church was full. Dr. Whittemore preached from the text, "Awake, oh, north wind, and come, thou south; blow upon my garden, that the spices thereof may flow out."

— DR. HOOKER has issued his report on the Royal Gardens at Kew for last year. The number of visitors has not been quite equal to either of the two preceding years. Sunday visitors embody more than two-thirds of the total number on all the other days of the week; Monday, the "artisans' day," showing considerably the largest numbers of any of the week days, and Dr. Hooker speaks of the almost uniformly orderly conduct of the visitors on that day. In the Gardens themselves, no change of importance has been introduced.

— WE would remind intending exhibitors at Birmingham, that to-day is the last for making entries of implements, horticultural buildings, &c., and that Tuesday next, the 25th instant, is the latest time for making entries to show table decorations. On reference to our advertising columns it will be seen that a final edition of the schedule will be ready for issue in a few days; but we are authorised to state that in no important particular does it differ from the schedule already in the hands of our readers. Intending exhibitors will, however, do well to get a copy of the new edition—it may be interesting to know that 5,500 copies of the first edition have been distributed.

— SEFTON PARK was formally opened by H.R.H. Prince Arthur on Monday last. It is situated about three miles from the Exchange, and will be a great boon to Liverpool. It contains 382 acres, 115 of which are to be let off in building leases. It is to contain a cricket and review ground. It has a large lake, with a depth of about four feet, and is thus safe for skaters. This is fed by several little streams, which twist and turn about, and are prettily laid out, two of them springing from rock grottoes or cascades; little waterfalls are constructed all along their courses. A year at least must elapse ere the whole of the departments in this park are completed. The roads and footpaths are wide and well laid down, and the drainage arrangements perfect.

— THE broccoli growers in West Cornwall are greatly aggrieved by a contemplated attempt on the part of the owners of the small plots of the lands, to increase the rent-charge on the extensive broccoli-growing lands. A large and influential meeting has resolved to use every effort to resist the increase, if necessary, by an appeal to the Legislature to alter the 22nd clause of the Tithe Commutation Act, which sanctions a higher charge on gardens than on agricultural land, the appellants contending that the clause was intended for a limited time only, and that broccoli-growing cannot be fairly included in market-gardening.

— THE Earl of Shrewsbury again offers the British public a privilege and a warning. The grounds around Alton Towers will be thrown open to them as usual, but, as we infer, solely during their good behaviour. Last year, it may be remembered, towards the close of the season, his lordship expressed his dissatisfaction at the excesses sometimes committed by excursionists, and as he traced their origin to drinking habits, he announced, as his own solution of the licensing problem, that "unless people ate they should not drink." Some such plan is to be adopted during the present season, for the Earl states that the refreshment-rooms are to be open "only at meal times."

— THE Sunday promenade in the Zoological Gardens, like most other *al fresco* entertainments, may generally be said to commence for the summer season about Whitsuntide. The fine weather, so entirely unexpected by all but the profoundly weather-wise, allured no fewer than 45,000 visitors into these gardens on Whit Monday. These gardens just now are very beautiful. Notwithstanding the bleak cold weather we have had lately, the vivid young green of the trees is profusely decked with the bloom of chestnuts and crimson hawthorn, laburnums, rhododendrons, lilac, and so forth. To lovers of nature, animate and inanimate, these gardens afford real pleasure.

— GRAPE culture has become so extensive in California that some growers are at a loss to know how to profitably work up the surplus product, and the manufacture of saccharine substances from ripe grapes is now exciting attention. It is found that not only can a sweet viscid substance be obtained simply by boiling the juice, but that crystallised sugar can be easily manufactured therefrom. For this purpose the sweetest grapes are allowed to hang until they begin to shrivel. They are then picked, rapidly pressed, and the juice boiled to a thick syrup before any chemical change can take place. The syrup is placed in tight casks, and allowed to stand for four or five months, at the end of which time about two-thirds of the mass are found converted into sugar.

— SAYS THE *Times* notice of the flowers at the Crystal Palace:—
The specimens of *sarracenia drummondii*, of the *imantophyllum minium*, of the *cyanophyllum magnificum*, of the *sarracenia drummondii*, and of the *sphaerogyne latifolia* call for distinct notice.

And they shall not call in vain, and the distinct notice *Punch* gives them is that they are sesquipedalian kisses. We shall have the really lovely flowers, the Fairies of the Old Creation, crying out for new titles next. Who remembers, or rather, who forgets, Barry Cornwall's Weavers' song, "Tis better to Sing than Grieve?"—

Come, show us the rose with its hundred dyes,
The lily without a blot,
The violet, deep as your true-love's eyes,
And the little forget-me-not.

Are we to have this re-written in the following fashion?—

The *Rosa desbenhaulitiana*, come, show us;
The *Lilium separabilis*, white,
With the *Viola rannunculifolia* endow us,
And the wee *Mysotis palustris* hight.

—Punch.

— FLOWERS, says *Harper's Weekly*, exert a wonderfully refining, influence upon character. There are few who are not susceptible to it, under favourable circumstances. The model farmers of olden times, who begrimed his wife or daughter a bit of land to beautify, who denounced all blossoms which resulted in no marketable fruit as useless, and ploughed up the bright pinks and marigolds with ruthless hand, has passed away, we trust, or at most but a few of the species remain. It is becoming more and more the pleasant fashion, not only in towns and villages, but in secluded rural homes where the plain farmer's family toil hard, for the children to have little plots of ground where they may raise flowers to charm the eye. If parents only realised the educating power of plants, and how keenly most children enjoy watching the growth and development of vegetable life, they would foster the desire they so often express "to have a garden of their own." Now, in the spring-time, let at least a few seeds and roots be obtained; let a bit of ground, or, if this is not possible, some flower-pots, be devoted to the amusement and instruction of the little folks. It will not merely keep them out of mischief to have some pleasant occupation in the open air, it will be health-giving and mind and heart improving. Don't forget the flower seeds!

GARDEN IN THE HOUSE.

BRACKETS FOR PLANTS.

SOME plants look so well against the wall of a greenhouse or conservatory that it is a wonder brackets are not in more general use than they are. It is not necessary that they should be so elaborate as that which supports the fine-leaved Begonia in the accompanying engraving; this is of course a matter to be determined according to individual taste and means. For growing plants in, the least ornamental form is just as good as any other. The simplest kind of bracket which I ever saw was a flower-pot with one side flattened, and having a hole near the top of the flat side, so that it might hang upon a nail in the wall. Some years ago I remember seeing a collection of Ferns grow against the wall of a greenhouse in these flat-sided pots, which were hanging thickly all over the wall; and the effect of the drooping fronds, which in many instances quite hid the pots, was exceedingly pretty. I see no reason why Mesembryanthemums should not be grown in such pots, by which means the wall of a conservatory might be covered with their blooms; and those who would like to see ribbon beds executed upon a wall, might be able with this genus alone to produce some curious effects. Wall gardening, in short, is a subject to which as yet little attention has been paid; but if well carried out it would doubtless be productive of the very best results.

W. T.

WINDOW ROSES.

NOTWITHSTANDING all that has been said and written respecting Roses, there appears to be room for further discourse on the subject, and this will always be the case so long as new crosses give rise to new uses and new experiments. Roses for the window is a branch of culture hitherto little touched upon, although through its means many may enjoy possession of this flower of flowers to whom, in any other form, it is emphatically denied. Some years ago I was induced to turn my attention to this subject, in consequence of a small collection of certain kinds in pots coming under my control. The drawing-room window of a suburban dwelling was the only field for experiment at command; but the air of the locality was pure, the aspect favourable, and the varieties, as trial proved, eminently propitious. In due time Roses came, and the possibility was proved of having charming flowers without a glass house and without a garden. Indeed, the produce of the window differed but little from that of the same varieties under glass in a special Rose house. The master-key of the position was the selection of varieties. It is not pretended, as a matter of course, that any Rose stuck in a pot will necessarily thrive under the special and peculiar conditions of window culture. But, given the requisite attention, and, as said before, the proper sorts, failure need hardly be apprehended. There are, however, certain essentials of procedure to be mastered by the window-cultivator of Roses. First he must have the following sorts: the plants on their own roots, and well-established as to size. Nothing in less than thirty-two-sized pots is permissible; twenty-four are better; but the dimensions, on the other hand, must not be too large, because many inconveniences, needless to particularise, would result from bulk. The plants themselves should be compact and bushy, well furnished with shoots from the very collar. Any kind of worked Rose must be avoided, because stocks of all sorts require far too much root-room for effective growth in pots. Liquid manure also, which forms an important element in the pot-culture of Roses, is apt to exercise a

detrimental influence on worked plants with limited root accommodation, through developing latent suckers, hurtful to the plants and deceitful, by their treacherous simulation, to inexperienced and unwary cultivators.

The routine of treatment to be laid down for window Roses is extremely simple. Repot them every year in rich fresh soil; whether in November or February is of little moment, provided they are kept "cloisth," warm, and shaded for a few days, after which they may be pruned into shape. See that they are sufficiently supplied with water, but not kept too moist, and occasionally administer an invigorating tonic in the form of liquid manure. Let this be clear, and let Peruvian guano, two ounces to the gallon. The foliage is to be kept scrupulously clean and free from dust. Seize every opportunity of exposing the plants to genial rains, in the absence of which subject them to an evening sprinkle with the syringe, particularly in the summer time, in any convenient spot, restoring them to their proper locality when somewhat drained. Occasionally sponging the leaves with soap and water will be a beneficial practice; but beware the suds do not soak into the soil, converting thereby pots of earth into pots of paste, to the utter discomfiture of the roots therein. Study the future contour of the plants in cutting blooms.

Let us now proceed to the paramount consideration—that of the choice of sorts. Four Roses are by far the most generally useful and reliable for the task we have in hand: Souvenir de la Malmaison, Mrs. Bosanquet, and the old white China, and the blush, frequently termed the "monthly rose." The two first-named flowers are greatly the best, yet the latter are pretty, and constantly in bloom, a point of much importance. There is a new white China, named "Ducher," highly promising for windows or for beds. We have next the Teas—Safranot, Madame Falicot, Vicomtesse de Cazes, and the brilliant-coloured Fabvier and Cramoisie Superieur, to give life and contrast. Some may feel disposed to add many undeniably fine pot Roses to the list, but pot Roses and window Roses are different things. In the latter, only those producing constantly new shoots, and upon every shoot a bloom, are really fitted for the purpose of growth in rooms. As soon, however, as the experimentalist feels master of his art, there is nothing to prevent him from endeavouring to extend his collection. Beginners should confine themselves to the first-named five, but the more skilled and confident may launch out "at discretion" in the kinds which follow, always keeping in mind that the plants must be upon their own roots: Admiral Nelson, Anna Alexieff, Docteur Andry, Elie Morel, John Hopper, Monsieur Noman,

Marquise de Castellane, Marquise de Mortemart, Princess Christian, Pauline Lansceur, Charles Lefebvre, Baron Gonella, Catherine Guillot, Bourbon Queen, La Quintine, George Peabody; the Teas—Devoniensis, Madame Braby, Madame Halphen, Pauline Labonte, Souvenir d'un Ami, Melanie, Willermoz, Niphets, Triomphe de Luxembourg, Odorata (old); the Noisettes Narcisse and Céline Forestier. Many of these will succeed, but must be adopted rather as probabilities than certainties, because, after all, in rose-growing, as in other things, something must be risked.

No window plant should stand permanently in a saucer, which is merely a device to save dirt and slop after watering, which should be done rather by total immersion than by sprinkling, which is only useful administered overhead. Plants should never stand in draughts, or be exposed to the beams of the scorching midday sun. When window Roses have done blooming, they should be set out of doors in any convenient place, until again beginning to grow. Removing the upper surface of the soil and replacing it with fresh is a valuable point of culture, and will be found of great assistance towards healthy growth. Dead leaves and bygone blooms should be quickly removed, the latter always cut off just above a plump, well developed eye. Rose trees kept close have always a tendency to be

Plant Bracket.

attacked by red spider. Watch carefully for the first inroads of this pest, and wash the backs of the leaves with soft soap and water.

It may be added that some of those glass-cases termed Belgian window gardens are well adapted for the growth of Roses, where a sunny aspect exists, with facilities for affording plenty of light and air. A few fine Roses such as have been named in this paper will convey a charm, a finish, and an interest to apartments that few other objects can give.—W. D. Prior, in "Gardeners' Magazine."

TEACHINGS IN TABLE DECORATION.

I thought I knew something about decorating a dinner-table, but I wanted to know more, so I went to the great show of the Royal Horticultural Society, at South Kensington, the other day, and there I learnt a great many lessons. I learnt that as fine feathers do not always make fine birds, so good fruit and good flowers will not ensure good table decoration, unless properly arranged; that fine fruit and choice flowers may be very beautifully arranged in dishes and vases, and yet be so placed on a dining-table as to be an inconvenience, instead of a pleasure, to the invited guests, and an annoyance to the host and hostess, whose friends might just as well be dining in another room or another house if they cannot see them and each other.

I learnt that there are two classes of table decorators—those who crowd on as much as they can, and those who put on as little as possible; that in each class there are people with good taste, people with bad taste, and people without any taste; that in each class there are those who run into extremes, and consequently into absurdities, in carrying out their particular views; that each style has its admirers; and that, amongst the ladies, it is an easy matter to see from the style of their costume to which style of table decoration they will give a preference. I learnt that it is possible to decorate with good taste in the heavy style, as well as in the light style, although there was not a good example of the heavy style to be seen there; that heavy fruits are only admirable on a table dressed in the heavy style, and are quite out of place in any arrangements of a light character; that highly odorous fruits, like pines and strawberries, ought not to be placed upon a dinner-table at all, but should be handed round at the proper time at a *diner à la Russe*; and that at such dinners it would be better, in my opinion, if no fruits were used as a decoration when flowers sufficient for ornamenting the table can be commanded.

I also learnt that a few flowers, well selected for size, form, and colour, and well arranged, will produce a more pleasing effect than a larger supply of what may be finer and choicer flowers, however well put together; that there should be a proper proportion between the size of the table and the sizes of the vases used upon it; that not only should vases be chosen to suit the size of the table, but that, in like manner, flowers should be chosen to suit the sizes of the vases; that large flowers should be used in the lowest dish of a vase, medium-sized flowers in the middle dish, and small flowers at the top; that dark colours should be used at the base, paler colours in the middle, and light colours or white at the highest part; that flowers of too fragrant a description should be avoided, or used very sparingly, lest they prevent some possessors of susceptible noses from enjoying their dinner; that large vases should not be placed near the edge or at the corners of a table; that the largest vases should be as far as possible from the edge of the table; that if there is room for other vases between them and the edge, these other vases should be decidedly smaller, and that their size should be smaller and smaller, in proportion to their proximity to the wine glasses of the diners.

I further learnt that the same rules which govern the sizes and the colours of flowers vertically, that is, from the base of a vase to its summit, should also be observed from the centre to the edges of the sum in all decorations that are flat upon the table.

All this, and much more, I learnt on the 15th instant, and yet I was not satisfied, so I went again on the next day, when I learnt something more. I learnt that if I want to give dinner-parties for two or even three days running, I can, by careful selection of proper flowers, make the same decorations answer again and again, provided that I arrange them in water, or in moss that is in water; that shallow dishes filled with sand are very inferior to deeper dishes filled with moss and water; and that wiring flowers is all very well for supporting flowers whose heads are too heavy for their stalks, but it will not keep up their pristine freshness, unless their stems are in water.

I looked over the names and addresses of the competitors, and I found glass and china merchants, whose object appeared to be to try how many different forms of receptacles for fruit and flowers they could put upon the table; I found Covent Garden Market represented with the main idea of showing both quantity and quality in the

flowers and fruit, in which their success was indisputable; and, lastly, I found amateurs, who, unbiassed by such views, or rather influenced by very opposite views, had endeavoured to produce a good table without stripping their houses or spending a fortune upon the decorations for one dinner; and I saw that four out of the five prizes awarded were taken by amateurs.

It must not be supposed that I am going to name the tables from which I learnt these various lessons; indeed those who arranged them would not be flattered if I were to do so, and for the following reason: more of my lessons were learnt from errors in judgment and taste on the part of the decorators, than from illustrations of their ability in the art. Yet those who saw them could not fail to be impressed with the amount of labour involved in getting together and arranging such a grand display of fruits and flowers, and it is very doubtful if anyone there passed a more enjoyable morning amongst the dinner tables than did—

AN IMPROVER.

GARDENIAS FOR CUTTING.

Who has not been charmed with Cape jasmines?—almost a name, I fear, for anything unusually sweet and spotlessly white. No kind of flowers, not even orange blossoms, are more charming for wedding and other bouquets. Six or eight blooms of *Gardenia Fortunei* around a white rose or camellia, with padding and fringing, would make a bridal bouquet fit for an empress. *Gardenia citriodora*, again, produces single white flowers that are better than orange blossoms, while the different varieties of *G. radicans* are charming for cutting either for vases or bouquets. The Gardenias are also well adapted for the decoration of rooms, as most of them flower freely in a small state, and have a neat habit. Of course only those who enjoy living in an elysium of sweetness could live with them; but there is one considerable advantage—that of introducing plants rather than cutting the flowers. And this brings me to note one frailty of the Gardenia. Soon after being cut it loses its white colour, and in the course of a day or two it dies, a dirty orange or yellow. Of course the flowers on the plant last longer. Some might select bridal bouquets chiefly formed of these flowers to send to a distance for a wedding three days hence. Don't do it. For the same day or the next they are safe, not later. Almost all the varieties are suitable for bouquet-work but *G. Stanleyana*, which is of quite a different character from the rest—in fact, a trumpet-flowering plant with white margin and purple throat, eight inches deep and five broad. It is sweet like the others, and is an effective flower for standing up in or hanging over a vase. The garden variety of *G. florida*, *G. Fortunei*, *radicans*, and *radicans major* are the most useful.

Sometimes Gardenias are called greenhouse plants, but no one can cultivate or flower them in perfection treated as such. They luxuriate in a high temperature and a genial bottom heat from fermenting materials when flowering and making their wood. For the rest, they should never be under 50° even when dormant. They do well in a mixture of peat and loam, half and half, coloured with sharp silver sand, and darkened and enriched by, say, a sixth of well-rotted cow-dung.

The best season for potting is when they are in full growth after flowering. A moist temperature of 70° to 75° suits them well until the growth is finished, when they can be removed to a cooler house until within six weeks of the time the flowers are wanted. Mealy bug is very partial to them. Rapid growth in an atmosphere charged with ammonia from decomposing manure is the best preventive. A drachm of pure alcohol, applied through a showerer, is a certain exterminator.

Rhipis humilis.—This is an exceedingly pretty "dwarf-fan palm," and one from its stature peculiarly suited for room decoration. It does not, like most of the small palms seen in our hothouses, send all the leaves from the root, but has a distinct woody stem not much thicker than the finger, and the most graceful little pillar of leaves that can be conceived. There is a very pretty specimen of it in Mr. Vergette's nursery, in Edgbaston.

Tritelia multiflora as a Pot Plant. I can endorse all that "R. D." (p. 454) says about this interesting plant, except upon borders. It is sweet as a primrose if unrooted or unbranched; but touch it not, unless you can revel in the smell of onions intensified a hundredfold. How "R. D." could write that the cut flowers can be mingled with others, without the unpleasant smell which unfortunately belongs to them being discernible, is beyond my comprehension. They are simply and wholly intolerable in a house.—T.

Bramble Leaves in Winter.—In one of the February numbers of a respected contemporary of yours, the leading article of which is devoted to not very dignified abuse of poor William Cobbett, Charles Dickens, and other distinguished men, who did not happen to be quite so numerous about gardeners as the writer of that speech, a recommendation from Mr. Wm. H. Holbrook, Smethwick, in favour of the leaves of the common bramble for garnishing the dessert. To the note the following editorial remark is appended:—"But bramble leaves are not to be had during the winter.—Eds." Now in my part of the country, bramble leaves are not only to be had during the winter, but on this 8th day of May I could gather cartloads of leaves of the past year.—J. M.

THE INDOOR GARDEN.

THE INDIAN AZALEA.

This must always be a favourite, not only on account of the beauty of its flowers, but also on account of its free and cleanly growth, and dressy appearance even when out of bloom. It is likewise one of the best of plants for yielding cut flowers for bouquets of all kinds with which I am acquainted, and therefore merits our best attention.

SOIL.

This must be sandy peat—a good peat with a fourth part or nearly so of sharp sand. Some peats have a good deal of sand in their composition, and of course in such a case a smaller quantity need be added. But decidedly sandy the soil should be, no matter how that is brought about. As a rule, people do not use enough of good sand in their Azalea soil. There are some soils that go by the name of peat, but which, being made up of a spongy and marshy kind of dark loam, have very little in common with good peat, and should therefore be avoided. Nothing is more common in garden books and papers than to find it laid down that the soil should be used "in as rough a state as possible." That is not necessary; it is not good management. If a pot is well and thoroughly drained, as it should be, with a couple of inches of potsherds, and over that a very thin layer of clean moss, the soil may be fine and thoroughly mixed up, and the plants will prove all the better for it. It should be passed through a coarse sieve—rubbed through it if necessary—the old fibres, roots of brake, and similar material generally abundant in peat, being removed.

POTTING.

If there is any one thing to be more particularly insisted on than another it is the "firming" down of the fresh soil that is placed round the ball of a plant that is getting a shift. Many employ the right kind of soil and sand, but leave the fresh compost in a much softer and looser condition than the old ball; a mistake that often proves fatal to many plants. Even some gardeners pot a plant so loosely that the slightest pressure of the hand sends down the new soil an inch or two. What is the result? Why, the ball being full of feeding roots loses its moisture quickly, and then, in consequence of the earth that surrounds it being much softer than the consolidated ball, the water that is poured on slips down through the fresh soil at the sides, in which there is as yet no roots, and thus affords no moisture to the mass of roots in the ball. After a little while the ball becomes quite dry, and then death ensues. Many Azaleas perish annually from this cause, or the nearly similar one of the pot being wet at the top and not thoroughly soaked through; but that is easily guarded against by giving thorough waterings. In potting Azaleas, the soil should be rammed quite firmly with a short blunt stick, and in several stages as the soil is put in, if the pot and specimen are large. In a word, the soil placed round the old ball in potting should be made as firm as the ball itself, and then the water will sink through all parts equally, free and vigorous growth will ensue, and accidents will be avoided. Should the cultivator discover a plant perishing from either of these causes, the remedy is to plunge it into a tub of water deep enough to cover the rim of the pot, and there let it soak for an hour or two, till it is thoroughly saturated and refreshed. Azaleas are free feeders, and therefore should be well watered at all times. No plant better enjoys a thorough soaking; and in the case of large pots or tubs it should be given twice or thrice.

TRAINING.

Many Azaleas have a dense thicket of cross shoots immediately over the pot; so much so that the hand can scarcely be got in to lay hold of the stem, and potting becomes an awkward operation. It was at one time thought that this was necessary to ensure a bushy plant. Instead of that, however, some of the handsomest-shaped and finest plants ever seen at our exhibitions have stems clear eighteen inches from the pot. The Azalea is so tractable, and yields so readily to the will of the trainer, that the shoots may be tied down and the specimen made to look as well as if you let the stem break forth close to the soil. Better, in fact, because by having some length of clear stem the operations of potting and training are much facilitated; and, after all is over, the branches droop down gracefully over the edge of the pot. Exhibitors of the Azalea generally train it so as to form a rigidly pyramidal outline, and it is the best way, with the exception of the rigidity. It is not nice to see beautiful plants trained as precisely as a sugar-loaf. Naturally, the Azalea assumes an agreeable outline; and there is no reason why, in some instances, it should not be allowed to take any shape it likes. In order to form a pyramid a central stake is

necessary; but it should not rise above the top of the plant. The leading or strongest shoots should be attached to this, and then the training should begin by gently tying down the lowermost branches first to the position desired, and following with the others. This shape may not seem pleasing at first, but soon the plant will have made a fresh growth, and will look much improved. The aim should be to make the specimen equally well furnished on every side, and not, as in some specimens now and then shown, good on one side and a bunch of bare stakes and shoots on the other.

TREATMENT AFTER FLOWERING.

When Azaleas have done flowering they should be put into a moderate and genial moist heat, to make their growth; that is, if it is convenient to do so. But if not, never mind; as they will flourish in a well-managed greenhouse or conservatory all the year round. If, however, it can be done, give a gentle close heat when they are growing. At that season they should be freely syringed, both in the morning and afternoon, and immediately after the afternoon syringing the house should be shut up, so as to retain a moist and genial heat. Many have but one house in which to grow their Azaleas, and that one it may not be quite convenient to shut up; but they need not despair of growing a good Azalea. It is a very tractable, accommodating plant. We are merely giving the treatment pursued by those who grow it best. A slight shade must be given when the sun is powerful in summer; but it must be slight, and only applied during the heat of summer and when the plants are in a soft and growing state. When growth is finished, and the plant approaching the "ripened" stage, shade is not desirable. They should not be shifted into large pots until they have quite filled with roots those they are already in. See that the ball is thoroughly moist before repotting it.

Pinching off the strong shoots should be attended to during the growing season, particularly in the case of young and freely-growing specimens; tying down strong shoots is also desirable. Pinching should not be done late in the season. Thrips is the chief and most destructive insect pest with which the Azalea is afflicted. The best way to get rid of it is to fumigate the house with tobacco or tobacco paper. It should be done in the evening, and, if convenient, during a still evening. Some fumigate two evenings in succession; it is a better plan to do so three or four times in succession, an interval of four days being allowed to elapse between each smoking. Fumigation destroys the insect, but leaves the eggs safe; the successive smokings recommended, however, catch the young fry as they come out, and finally exhaust the stock of vermin. If a collection of Azaleas is clean, care should be taken to examine additions that are made to it, as vermin are often introduced in that way. Fumigation should not be carried on when the leaves of the plants are wet or very moist.

It is a common practice with Azalea-growers to place the plants in the open air in summer. This is by no means necessary, as some of the largest and finest Azaleas we have ever seen were kept in a conservatory the whole year round. However, in country places, where the glass houses do not get regular and skilful attention, it is safest to put them out after they have made their growth, as by so doing they get well cleansed by the summer rains.

As it is of some importance to know the best kinds, I append a list of the most beautifully coloured and freest growers: Beauty of Reigate, Coronata, Criterion, General Williams, Ivoryana, Eudalie Van Geert, Chelsoni, Perryana, Cedo Nulli, Broughtoni, Rosalie, Admiration, Louise Margottin, Murrayana, Lateritia, Gem, Extranii, Magnet, Queen of Whites, Reine Blanche, Juliania, Halfordiana, Rubens, Ivoryana Improved, and Modèle.

A.

Plant Remedies for Insect Pests.—With the approach of summer weather this subject has a practical interest for medical men and their patients. Linnæus informs us that the seeds of the *Absinthium maritimum* are deadly to the flea; and we have likewise heard that the odour of the alder is equally obnoxious to other insects. It is said by the devotees of botany that on a hot summer's day the cattle may be seen to cluster round the alder for protection against the sting of flies. We have thought sometimes, in our summer rambles, that the verdict of the wise was unproven. We entertain a strong belief that the perfume of the camomile is destructive of the *Acarus scabiei*; and we use it accordingly in our pomades for the treatment of scabies. Bazin was wont to recommend, for the same purpose, an unguentum antehemidis; and our Italian contemporary, the *Giornale Italiano delle Malattie della Pelle*, reminds us that an infusion of camomile flowers has been recommended as a wash to the skin, for the purpose of protection against gnats. Gnats are said to shun the traitorous perfume; and, if such be the case, it would be easy to convert the essential oil of the anthemis into an agreeable lotion, like that of lavender water or eau de Cologne.—*British Medical Journal*.

THE FLOWER GARDEN.

GOURDS FOR ORNAMENT.

As the season for planting out these singular plants is now at hand, a few words on their treatment may not be out of place. The Gourd tribe is capable, if properly used, of adding much remarkable beauty and character to the garden. They are as a rule, however, rarely seen in variety and beauty. There is no natural order more wonderful in the diversity and beauty of its fruit than that to which the melon, cucumber, and vegetable marrow belong. From the writhing Snake-cucumber, which hangs down four or five feet long from its stem, to the round enormous giant pumpkin or gourd, the grotesque variation, both in colour and shape and size, is marvellous. There are some pretty little gourds which do not weigh more than half an ounce when ripe; while, on the other hand, there are kinds with fruit as large as a good-sized barrel. Eggs, bottles, gooseberries, clubs, caskets, balls, vases, urns, small balloons—all have their likenesses in the gourd family. Those who have seen a good collection of them will be able to understand Nathaniel Hawthorne's enthusiasm about these quaint and graceful vegetable forms when he says, "A hundred gourds in my garden were worthy, in my eyes at least, of being rendered indestructible in marble. If ever Providence (but I know it never will) should assign me a superfluity of gold, part of it shall be expended for a service of plate, or most delicate porcelain, to be wrought into the shape of gourds gathered from vines which I will plant with my own hands. As dishes for containing vegetables they would be peculiarly appropriate. Gazing at them, I felt that by my agency something worth living for had been done. A new substance was born into the world. They were real and tangible existences, which the mind could seize hold of and rejoice in." Of course the climate of America is much better suited for fully developing the gourd tribe than ours, but it is satisfactory to know that they may be readily, and beautifully grown in this country.

Gourds.

There are many positions in gardens in which they might be planted with advantage—as, for instance, on low trellises, depending from the edges of raised beds, the smaller and medium-sized kinds trained over arches or arched trellis-work, covering banks, or on the ordinary level earth of the garden. Isolated, too, some kinds would look very effective, particularly if trained over an old stump or branched stake. In fact, there is hardly any limit to the uses to which they might be applied. A very curiously covered tent might be made of them by using a few rough branches of trees as a framework, and the gourds planted round the sides in rich earth.

OUTDOOR CULTIVATION OF THE CAMELLIA.

It was affirmed, not long since, that the Camellia is unfitted to be an outdoor flowering shrub, because of the damage that unfavourable spring weather inflicts on its flowers. That such damage may result under the most unfavourable conditions I admit; but no one would plant any choice flowering shrub where it could be swept by all the winds that blow, or where it lacked all ordinary shelter and protection. That Camellias have proved themselves to be at once amongst the hardiest of evergreens and, at the same time, in moderately sheltered situations, the most beautiful of flowering shrubs, plenty of proofs exist; and probably in no place will better examples of these statements be found than at Glen Eyre, Basset, near Southampton, the residence of Mrs. Eyre Crabbé. In that locality, however, the earliest examples of outdoor-grown Camellias are to be found on the kitchen-garden walls at North Stoneham Rectory, which stands in a low-lying situation in the Itchen Valley. There are some splendid

specimens, each covering a space of wall twenty feet by nine feet, and having stems at the base from seven to eight inches in diameter. These trees are one mass of close laid wood and foliage, and in the early months of the year are literally covered with blossom. Either from a fear of mischief from early frosts, or to enforce a precociousness of bloom, these Camellias are each protected by a broad coping of boards, from which, during severe weather, mats are suspended, and thus a certain amount of protection is given. Bushels of flowers are annually cut from them; and of course their cultivation is regarded as being a perfect success. Glen Eyre is situated on the high lands that overlook Southampton Water, the Victoria Hospital, and much of the charming surroundings of that picturesque locality. The gardens occupy the head and sides of a pretty dell looking due east, and upon the north are considerably sheltered by groves of Fir trees. The soil naturally is poor, being a combination of black bog earth, gravel, and clay, all now pretty well mixed by human labour; and in it, in all sorts of situations, and especially upon the sides of long grassy declivities, many of our best ornamental coniferae thrive most

Camellia growing out of doors at Glen Eyre.

luxuriantly, whilst Rhododendrons, Azaleas, and indeed all kinds of ornamental shrubs, grow in rich profusion. The working out of the original design of these pretty gardens during the twelve years that have elapsed since the first sod was turned upon the once barren heath, has necessitated a large amount of well-directed thought and labour; but Mrs. Crabbé has, in her able gardener Mr. Stewart, a worthy supporter; and their combined efforts have resulted in the production of one of the most charming gardens of which the south of England can boast.

Camellia culture in the open air was first attempted here by planting against the stable walls such kinds as Double White, Imbricata, old Double Striped, Monarch, and others; and these, without any other protection than the building affords, have thriven and grown in the most satisfactory manner. The next step was the planting out as a single specimen a rough plant of the old Double Striped, and which had been growing for several years in a tub in the house. Its position, though sheltered by buildings north and east, admits of its being frequently swept by south-east winds; and, as it stands midway between the conservatory and a block of shrubs, the current of air to which it is exposed is occasionally very severe. In spite, however, of this disadvantage, and also that it gets no dressing, but is entirely growing upon a surface of

gravel, the plant has thriven amazingly, and carries yearly hundreds of blooms, scarcely one of which when fully expanded but would vie in quality with flowers of the same kind grown under glass. It is now about eight feet in height and the same number of feet through, and is, as the sketch on the preceding page will show, a luxuriant specimen. If there were no other Camellia growing unprotected in the open ground than this one, it would sufficiently prove that the plant is not only an outdoor flowering shrub, but also one of the most beautiful and most effective. In this garden, however, there is no such limitation, for in all directions—in beds, in borders, and in secluded spots—Camellias crop up, growing well, and in the most robust health. On the sides of a grassy slope looking to the north-east, are two beds of Camellias that have been planted there several years, and are now developed into perfect masses of wood and foliage. I look upon these beds as presenting the most favourable example of the capacity of the Camellia to withstand severe weather and complete exposure; and the blooming is of the most abundant kind. During the past few years large numbers of young Camellias have been turned out, and among them, in addition to those already named, may be mentioned Lady Hume's Blush, Tricolor, Florida, Chandeli, Anemonaciflora, Juliania, Mathottiana, Valtevardo, Adrien le Brun, Duchess of Northumberland, and Eclipse. No special preparation is given to the soil, but when young plants are turned out, a little good compost is added, which greatly facilitates rooting.

Mr. Stewart gives it as his experience that, should no great amount of growth result for the first year or two, no discouragement should be felt; but when the plant is fairly established, then a permanent and continuous growth is certain. As a rule he thinks the Camellia to be very accommodating with respect to soil, provided it is sweet and well drained. Unlike the laurel, its summer shoots are never made until all danger of spring frost is past; but both wood and foliage are of the hardiest kind. Mrs. Crabb, who has had long experience of outdoor Camellia

planting, affords no covering of any kind. Glen Eyre is at all times worthy of a visit, but especially is it so when its Camellias are in full bloom, and when the charming spring flower garden that exists there is in the height of its beauty.

A. D.

CALADIUM ESCULENTUM.

This species has, for flower-garden purposes, proved the best of a large genus with very fine foliage. It is only in the midland and southern counties of Great Britain that it can be advantageously grown, so far as I have observed; but its grand outline and aspect when well developed make it worthy of much attention, and of a prominent position wherever the climate is warm enough for its growth. It may be used with great effect in association with many fine foliage plants; but Ferdinandia, Ricinus, and Wigandia usually grow too strong for it, and, if planted too close, injure it. This may have been noticed, particularly in cases where it was used as a bordering to masses of the strong-growing kinds above named. For all kinds of stonework, vases, &c., it is peculiarly effective and beautiful. This plant requires, above all others, a thoroughly

drained, light, rich, warm soil. In times of great heat, it should be plentifully watered, and occasionally with liquid manure. The latter end of May is the best time for planting; and if groups are formed, the plants should have a space of 2 feet or $\frac{1}{2}$ feet between them. The foliage generally arrives at its full beauty and development in August and September. At the approach of cold frosty weather, all the leaves, or all but the central one, should be cut down to within an inch or two from the crown, and a few days afterwards the tubers should be taken up and left on the ground for a few hours to dry; they should then be stored on the shelves of a greenhouse, or in a cellar, or other place where they will be sheltered from frost and moisture. By placing the tubers in a hotbed in March, plants may be obtained with well-grown leaves for planting out in the open air about the end of May or the beginning of June.

ORANGE TREES.

The time has now arrived when these may be placed in the open air with much advantage. No plant, perhaps, has had more attention bestowed on it, and with a poorer result, than the orange in this country.

In old times it was very popular, but not of late, people being frequently deterred from cultivating it by the scraggy appearances generally presented by the trees in most instances. The whole gist of successful orange-tree culture in England consists in letting them *make all their growth in the open air*, and keeping them in a rather dark cold place all the winter. The more at rest they are kept during that season, the more perfect will their development prove in the following summer. The best of all structures is an outhouse with side light—the walls, &c., thick enough to prevent frost entering, and only as much light from windows or side sashes as will keep the plants from being quite in the dark. In fact, such a light as prevails in an ordinary dwelling-house will suit them to a nicety. Wherever they are allowed to make their growth under glass in spring, and then put out, failure always results. The trees should

remain in such a house till the month of May, getting abundance of air and being kept cool to prevent them starting a bud before placing-out time comes. They may be put out at any time in the month the cultivator's judgment may select, say from the 12th to the 25th, or even the end of the month, if it prove unusually cold or severe. At first they might with advantage be put in some sheltered place for a week or two, and then placed on the terrace, or in some other sunny and favoured position. The growth will soon commence, and prove equal to any change of temperature or vicissitude that may assail it. Give plenty of water, and if the roots have well filled the pots, a little top dressing of about an inch of rotten manure, to be covered for appearance sake with a dust of fine mould. The waterings required during the summer months will wash this down to the roots and do much good; but it should be observed that it is only necessary in cases where the pots are well filled with roots, which require more food than the soil can well afford. Take the trees in October, say about the end of the month. Good turfy loam, with a little sand and some well-rotted

Caladium esculentum. (After Vilmorin.)

vegetable manure, will be found the best soil, while abundant drainage is indispensable.

The first time I ever saw orange trees in England grown well as I describe, was at Arundel Castle, where they are placed along the walks in summer, and stored in a half darkened house or shed in the pleasure grounds during winter.

Lately, at Holland House, I have seen magnificent trees trained in exactly the same way; the famous Hanoverian specimens are grown in like manner. At Holland House they are stored in a structure which was once a high arched stable, and which has now an opaque roof, having, however, lean-to glass houses thrown against its sides, which furnish side light to the orange trees. So they flourish almost without aid from artificial heat. It need hardly be said that if the object in growing oranges be the production of fruit and flowers, and not good specimens for open-air ornament, a very different system must be pursued. Plants treated in the way I recommend, are of course of great value as ornaments in the cool conservatory, or even in cool halls, during winter.

F.

EFFECTIVE FLOWER BEDS.

DURING a careful examination of a great many beds in the neighbourhood of London last year, the following combinations were selected as the most effective, and we now produce them as a guide to those who contemplate bedding out such plants. The weather has, however, hitherto been so cold, that even at Battersea Park no progress has yet been made in the way of bedding-out sub-tropical plants. In some places a few edgings have been planted; but that is all. These consist of *Sempervivum californicum* and *tectorum*, *Echeveria secunda glauca*, *Cineraria maritima*, variegated *Funkias*, *Gazanias*, and golden *Feverfew*.

Round bed.—Centre planted with *Aralia papyrifera* and a dark-leaved *Canna* interspersed; outside these a ring of *Wigandia macrophylla*, with a dark-flowered *Caleularia* here and there, and edged with blue *Lobelia*.

Round bed of *Erythrina Crista-galli*, with small plants of *Aralia papyrifera* at the edge.

Small oval bed.—Centre, nice plants of *Acacia lophantha* two and a half feet to three and a half feet high. Outside the *Acacia* small plants of *Grevillea robusta*. Groundwork of variegated vine and Japanese honeysuckle, edged with *Alternanthera paronychoides major* and a silvery saxifrage (*S. cristata*), the latter outside.

Small round bed with a *Dracena ferrea* in centre, dotted with *Chama-peuce diacantha* and medium-sized plants of *Echeveria metallica*; carpeted with purple *Oxalis*; edged with *Chama-peuce Cassabona*, and outside *Echeveria secunda glauca*.

Oblong-oval bed with centre of *Acacia lophantha*, outside this a row of green-leaved *Canna* and a broad margin of the common vine.

Small round bed.—Centre, *Dracena ferrea*, with a groundwork of young plants of *Amicia zygomeris*; outside the *Dracena* a ring of small plants of *Abutilon Thompsonae*, and edged with *Echeveria secunda glauca*.

Green-leaved *Canna* dotted over a bed of *Dahlias*.

Small bed of *Cineraria maritima* mixed with the old *Verbena venosa*.

Mass of *Acer Negundo* variegatum edged with *Coleus Verschaffeltii* in an isolated small glade in a high wood.

Round bed of *Aralia papyrifera*, with groundwork of *Plumbago capensis*, and edged with *Pelargonium tomentosum*.

Small round bed.—Bronze-leaved *Pelargonium* and *Nierembergia gracilis*, intermixed with a belt of a silver variegated *Pelargonium*, and edged with *Mesembryanthemum productum*.

Gladioli thinly planted in *Rhododendron* beds.

Wigandia macrophylla edged with *Chilian beet*.

Edgings of variegated *Dactylis* and *Viola lutea*, plant for plant, backed with common blue *Lobelia*; good in all cases, particularly so in the case of a bed consisting of young *Dracenas*.

Panicum palmifolium, and *Solanum marginatum*, dotted over a carpet of *Alternanthera*, *Mesembryanthemum*, and *Iresines Lindenii* and *Herbstii*.

Small bed with vase in centre, next *Aralia papyrifera*, and edged with *Geranium anemonifolium*.

Acacia lophantha excellent in any kind of bed.

Small beds of mixed *Fuchsias* edged with green *Saxifrage*.

Arundo Donax versicolor mixed with *Sonchus laciniatus* and a flowering edging.

Mass of green-leaved *Canna*s surrounded with a belt of *Chilian beet*, and edged with *Centauraea gymnocarpa*.

Panicum palmifolium, very good as an edging to medium-sized foliage plants.

Round bed of *Castor-oil* plants, with a belt of *Chilian beet* and edging of variegated *Coltsfoot*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Achillea aurea.—This is one of the showiest, if not the showiest, dwarf member of its large family, and is admirably suited for the rock-garden or choice borders, for bedding out, or edgings. It grows twelve inches or more high, has finely cut leaves and bright golden yellow flowers, abundantly produced, and appearing for a long time in succession on strong plants recently transplanted into rich ground. (See "Ainsworth's Botanical Garden," Hall.)

The Silver Saxifrage of Walls.—One day when visiting the garden of the celebrated botanist of Bussolengo, in Switzerland, I was not a little pleased and surprised to see a fine rosette of the noble *Saxifrage longifolia* growing out of the face of the wall, like a silver star. The wall was a retaining one, but much exposed to the sun, and the garden was in a warm lowland part of Switzerland, where such plants would find greater difficulties than with us. There can be no doubt that these charming alpine plants may be readily grown on old walls in this country. To establish them it is better to sow the seed in the chinks, &c.—W. R.

Iris nudicaulis.—Do lovers of hardy plants sufficiently know and esteem this? I think not. It has the vigour of the German *Iris*, which thrives so well on all soils in town and country, and the dwarfishness of the old *Crimean Iris*. It is, however, much sturdier than this, and is, in a word, second to no hardy plant introduced of late years. It is suited for the front ranks of the herbaceous border, and also well deserves a position among the more vigorous plants in the rock-garden, being so dwarf. It should be in every garden where early summer flowers are valued. I first saw it in the Paris gardens in 1867, and early brought home a plant, which have since multiplied, so that the plant is now easily obtained. W. R.

Gentiana asclepias as an Edging.—At Priory Hill, St. Neots, this lovely little plant is extensively used for edgings. They vary from nine to eighteen inches in breadth, and when in flower are extremely beautiful. Mr. W. Ratcliff, who has been gardener at Priory Hill for upwards of a quarter of a century, had at first only a small plant of it, but he has gone on increasing it till he has accumulated nearly 150 yards of it. To see its thousands of bright blue flowers nestling thickly and closely to the evergreen foliage is a sight worth seeing. As an edging plant this *Gentian* ought to stand in the foremost rank, as it far surpasses many of our more tender plants now cultivated for that purpose. K.

THE FRUIT GARDEN.

THINNING FRUIT.

THOUGH trees in a state of nature may produce fine crops of fruit, it is only on rare occasions, when the greater part of the blossom gets destroyed, that they produce a crop of *fine fruit*. Go into Covent Garden with a poor sample of fruit, and you will be fortunate if you recompense yourself the cost of plucking and carriage to market; take, on the contrary, a sample of fruit nicely packed, and you sell at once at the top market price. Now, the difference between poor fruit and fine fruit is just the numerical quantity produced. For example, a tree in good health may have sufficient vigour to bring, say five hundred fruits to great perfection; if you leave upon it one thousand fruits, they will only be half the size, and perhaps not that. Every tree has its fruit-bearing capability, and beyond that it cannot go; but if we want fine fruit it is always wise to reduce the limit of production. This reduction may be made either by thinning the fruit as soon as it is set, or by reducing the number of bearing branches, or by both. The first thing, however, should be to apportion the branches to the size of the tree. No two branches should be allowed to cross each other, nor should they be so thick or close together that the sun's rays cannot in the height of the season penetrate to every part of the tree. Thus you will get fine, clean, well coloured, richly flavoured fruit—fruit that you may be proud of; but if you allow the branches to remain thick, so that a part of the fruit is shaded, then an inferior sample and a low price at market must be the result. If a humble, but at the same time earnest illustration of the doctrine we wish to inculcate is desired, look to Gooseberry-growers; they know they cannot have size and quantity at the same time, and therefore they reduce the crop of their prize kinds to a few fruits upon each plant. If we do the same with our Apple and Pear trees, we shall see less in our markets of what the salesmen call seconds and thirds. But there is yet another aspect in which this subject may be approached. Fruit-growing north of the Midlands is too frequently considered a lottery in which the winners do not gain much. Well, it must be confessed the chances of success decrease with the neglect of cultivation. If trees are left to the sole care of Dame Nature, and go untrained and unpruned, we must not be surprised if in the struggle for existence they produce inferior wood and that wood is badly ripened. Therefore the further north we go the greater the necessity for good cultivation and careful training and pruning. There is scarcely a neglected fruit tree in existence which would not pay for having

half of the worst wood cut clean away, while in many cases it would be wise to cut all away and begin again. This may be done either with the same kind or by grafting with a superior one. And really what is the use of growing inferior fruit where good fruit may be had for the same trouble? Who would plant the Keswick Codlin when Lord Suffield may be had at the same price? Or what is the use of the scores of inferior Apples when Bleinheim Orange, Normanton Wonder, and other good kinds may be purchased at nearly the same price? It would not be wise to confine ourselves to a very limited number, as some bloom early and others late, so as to give several chances of a crop; but if we take a dozen varieties of kitchen apples and the same of dessert fruit the chances are that we shall not leave many other varieties to covet; and the same may be said of Pears and Plums, but in a more limited degree. Those who have been growing inferior varieties would do well to avail themselves of the power of improvement which grafting affords, and an old tree may be grafted all over; in this way they are soon brought into profit, and with superior kinds that profit will increase every year. We cannot too strongly urge this fact upon the attention of our country friends. Many of them have large orchards of inferior fruit, good enough for making cider, but not good enough to bring a profitable result from market. To all so situated we would say, cut over and graft, and in three years you will thank us for the advice. Even at a shilling per peck Apples are not bad speculation, and bring home in the course of a season a considerable amount of money.

W. P. A.

THE GRAPE VINE IN THE OPEN AIR.

Some will call in question the propriety of considering the Vine hardly at all. Our first care will therefore be to establish the fact of its being hardy. True, its culture out of doors has gone greatly out of fashion of late years, and various reasons have been assigned for it: such, for instance, as the extraordinary increase of hothouse grapes, the improved tastes of the population, the larger importation of foreign fruits and wines, and the deterioration of the climate. The two first are perhaps the strongest reasons for the decline of grape culture out of doors. Unless in exceptional circumstances, it must be admitted that out-of-door grapes are not equal to those grown under glass. And yet, throughout the greater part of England south of the Thames, grapes may be ripened in the open air, equal and often superior to the usual run of those grown in cool vineeries; and as to taste, I know it is a favourite argument that as our very remote progenitors feasted on crabs and sloes, so our more immediate forefathers enjoyed grapes filled with verjuice. Unfortunately for this hypothesis many of us have eaten out-of-door grapes of excellent quality. True, we have more fruit now, both home and foreign. But we have likewise more mouths to eat it; and I question if more or better comes to the share of all than in the olden time, when our fathers, secular and holy, were busy planting vineyards on the sunny sides of their hills, and eating the fruit, or drinking the wine thereof. The climate's deterioration theory won't hold water for a moment. On the contrary, the climate is improving every year. It is far drier and warmer than it was in those olden times when vineyards were thick as blackberries throughout the country. Every forest cleared, swamp, mere, or wet field drained has ameliorated our climate, and made it better for the growth of the Grape Vine. Neither is the Vine, by any means, a tender plant. In a thoroughly ripened dormant state it is well nigh as hardy as the oak. It is frost-proof within a few degrees of zero, which we seldom reach in England. We are not left to speculation to establish the hardiness of the Grape Vine in England. The experience of many centuries has established its hardiness beyond all controversy. As far north as the Thames, and indeed in favourable localities far beyond it, the Vine will ripen its fruit in the open air in England in average seasons, when properly managed.

We have no proof that the Grape was assisted by artificial heat in England till towards the close of the seventeenth or beginning of the eighteenth century, and yet as early as the third century it seems that Britain was included among the Roman provinces permitted to plant vineyards. Vine culture had spread throughout the Roman Empire to such an extent as to produce a scarcity of bread and an excess of wine, resulting in famine and drunkenness; and hence many vineyards were destroyed, and no new ones permitted to be formed without imperial license. With the rise of the monasteries, Vine-growing assumed national importance. The monks had capital taste: in the choice of pleasant sites for their homes and the sunniest spots for their vineyards no landscape

artist or horticulturist has excelled them. Wherever they built an abbey or a monastery, thero they also planted a vineyard and formed a garden of herbs and of flowers. Many of the vineyards formed by them bear their ancient names to this day.

At Chilwell, where Mr. Pearson rears new and grows old grapes so successfully, it seems there used to be a famous vineyard. For Miller tells how, "in an ancient house, called Chilwell, near Nottingham, there yet remaineth as an ancient monument, in a great window of glass, the whole order of planting, pruning, stamping, and pressing of Vines. Besides, there is yet also growing an old Vine that yields grapes in sufficient quantities to make right good wine, as was lately proved by a gentlewoman in the said house. And," adds Miller, "there hath moreover good experiance of late years been made by two nobles and honourable barons of this realm, the Lord Chobham and the Lord Williams of Tame, who have had growing about their houses as good vines as are in many places in France." This is as true of many Vines in the England of to-day as it was in Miller's time.

In 1323 the Bishop of Rochester sent presents of grapes and wine to his sovereign King Edward II. from his vineyard at Halling, in Kent. Sixty years later the president of Trinity College, Oxford, Dr. Bathurst, is reported to have made as good claret as one could wish to drink; and Sir Henry Lyttleton, at Over-Arley, such as was not to be distinguished from the best French wines. The Duke of Norfolk had such a noble vineyard at Arundel Castle, that, about a century ago, in 1763, he had in his cellars sixty pipes of excellent Burgundy, much exceeding in quality quantities of Burgundy which were annually imported into England, and most of what is usually drunk in France. We read of most excellent grapes being grown on the walls of the Botanic Garden, Oxford, in 1702. About a thousand years before, the Venerable Bede wrote that the vine was raised in certain parts. Somers states, that in 1285 the Priory of Canterbury was plentifully furnished with vineyards. *Domesday Book*—that grand repository of old world facts—takes note of the extent and produce of several vineyards.

The Monks of Ely not only made wine and vinegar, but sold both. Martin, Abbot of Peterborough, planted a large vineyard in Saxon times. The king had a vine-dresser at Rockingham who was furnished with livery and necessaries for the Royal Vineyard by the Sheriff of Northampton and Nottingham. Wines were well known to the Ancient Britons; and the wine-press—the Anglo Saxon "*win win vingar*"—is engraved on ancient records. The Vineyard at Bury St. Edmund's was called the "Vine," and contained six acres of land, as appears from an abstract from the tide deed of the monastery; and besides this there was the Palace Garden containing one acre, two little gardens near the Chamberlain's Office, the garden called the Lecture Yard, several other gardens, and the Walnut-tree Yard containing three acres, showing that the monks did not forget to grow nuts to crack with their wine. The Vineyard was formed by Robert de Gravill, the Sacrist to the Benedictine Monks, in the twelfth century, "for the solace of his friends."

CHASSELAS.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Strawberry Vicomtesse Hericart de Thury.—This strawberry is pronounced, and proved to be on the whole, the best and most generally now grown. It is also considered the best variety for general cultivation in the neighbourhood of Paris, where strawberries are grown to a great extent. It is good both for forcing and growing in the open air. Can any of your readers tell me who raised it?

Vine Border.—Will you or any of your readers kindly say what sort of vine you intend to make where the subsoil is a free gravelly soil, and the soil a good deep sandy loam? The situation is in Kent.—*MARY F.*—[You are fortunate in having your garden on one of nature's ready-made vine or fruit "borders," and we should say you have little to do beyond planting suitable kinds. Perhaps, however, some of our vine-growing readers may have something to say in the matter.]

Fruit Trees on Walls.—I have moved about a little in what are called good gardens this spring, and it has been to my quite painful to see how fruit trees suffer from want of a little coping, temporary or otherwise. The whole production of peasant country, that is, small estates, is small, and is of no use except perhaps to harbour a few insects. We could have regular crops of fruit on our walls if the glass coping recently figured in *THE GARDEN* were generally adopted, or even if a common light temporary wooden coping, eighteen inches wide or so, were put up for a few months every spring.—*VATOR.*

A New View of Root-Pruning.—Popularly this is supposed to be quite a triumph for British fruit culture; while really it is only useful in special instances carefully performed, and a source of endless danger and expense to many. If we consider the processes of root-pruning, it will appear, after much thought, that if people will persist in feeling any more in very minute trees, root-pruning must be resorted to in order to keep them down; but for moderately-sized trees it is to be avoided if possible. It should, however, only be appealed to as a last resource, after all other modes of checking vigour and inducing fertility have failed. Root-pruning tends too much to weaken the whole system of the tree, to take away the powers of the plant which are required for the support of what fruit there may be produced. It is not exactly a weakening of the entire system of the tree which is required, but a retention of all its powers, and a direction of those forces towards the production of fruit instead of that of shoots.—*Field.*

THE ARBORETUM.

THE PLANES.

BY GEORGE GORDON, A.L.S.

IV.—THE MAPLE-LEAVED PLANE (*PLATANUS ACERIFOLIA*—*WILDENOW*).

This bears considerable resemblance to the Occidental Plane, especially in its broad, angular-lobed leaves and large seed-heads, but none whatever to the Oriental Plane, although considered by most writers as only a variety of that species, which is a great mistake.

The Maple-leaved, or, more properly, the Sycamore-leaved Plane, is a native of the Levant, Persia, and Western India. It was first introduced in 1724. Dr. Royle found it growing plentifully, along with *Platanus orientalis*, in the great Valley of Cashmere, forming a stately tree from fifty to sixty feet high, with a straight and lengthened stem, somewhat thickly furnished on the upper part with twiggish branches. The stems of the young trees are smooth and of a dark greenish-brown colour, while the stems of adult ones are never so smooth as those of the Occidental Plane, as the bark adheres longer on them, and scales off in comparatively much smaller and thinner pieces. The principal branches are tolerably straight, not very stout, and more or less uniform in size, with the lower ones somewhat horizontal, or slightly declining; the middle ones ascending or curved upwards at the ends'; and the upper ones more or less erect, and all amply furnished with slender sprays or twigs, which give the tree, when in full leaf, a rather thick and close appearance. This is a hardy vigorous kind, which commences growing later in the season than any of the other planes, and

Leaf of the Maple-leaved Plane.—Natural size, 8½ inches long, including footstalk, and 8 inches broad.

in consequence of which it seldom suffers from the late spring frosts, which prove so injurious to all the other kinds.

The leaves of *Platanus acerifolia* are large, rather thin in texture, broadly and acutely five-lobed or angled, with a few remote coarse serratures along the margins, and nearly straight at the bases, or but slightly tapering to the footstalk, which is long and rather slender. The balls or seed-heads are about the size of those of the Occidental Plane, but more bristly, and generally produced in threes, but frequently in twos and fours, at regular distances and wide apart on the peduncles.

It is sometimes called *Platanus intermedia*, and the largest tree of it near London is at Elmhurst, Finchley, where in 1840 it was fifty-six feet high, with a stem three feet in diameter.

There are the two following very distinct varieties of the Sycamore-leaved Plane:—

1.—*The Spanish Plane* (*Platanus acerifolia hispanica*—*Loudon*).

Why this kind has been called the Spanish Plane is not very clear, and no doubt originated in some mistake, for no kind of Plane in a wild state has ever been found so far to the westward as Spain. The leaves of this kind are very large, some-

Leaf of the Spanish Plane.—Natural size, 8½ inches long, including footstalk, and 8½ inches broad.

what fan-shaped, with five, shallow, broad, angular-pointed lobes, furnished on the edges with several large, wide serratures, and strictly heart-shaped at the base, tapering a little to the footstalk, which in some cases is two inches in length.

There are trees of this kind in the Victoria Park, twenty feet or more high, with ample roundish heads.

It has the following synonymous names:—*Platanus macrophylla*, *grandifolia*, *fabellata*, and *hispanica*.

2.—*The Spreading-Branched or Canopy Plane* (*Platanus acerifolia umbellata*—*Knight*).

This singular variety, when grafted standard high, forms a flat spreading head or canopy, full of rather long slender brown horizontal branches and semi-pendulous shoots, the principal ones of which have a tendency to curve upwards at the ends. The leaves of this kind are also generally larger than those of the species, with the lobes longer and more entire in the margin.

This variety of the Sycamore-leaved Plane is said to have originated in Lombardy, about thirty years ago, and was first introduced by the late Mr. Joseph Knight, of the Exotic Nursery, Chelsea.

The Deodar.—Will any of your readers kindly tell me if Deodars struck from cuttings make as fine trees as those from seed? Also, how the Deodar does grafted? I happen to live in a part of the country where this noble tree does beautifully, and even in the largest specimens never shows a tendency to debility or disease, and am anxious on the above points before planting a good many trees.—*CEDRUS*.

A Fine Tulip Tree.—Being on a visit at Coughton House, near Ross, I was astonished and delighted to see a very fine specimen of the Tulip tree (*Liriodendron tulipifera*) in flower, which is said to be in the Field next to the house. I believe this Tulip tree is unrivalled in England. It measures fourteen feet six inches at the base, and is over seventy feet high, and at this present time is one mass of green leaves and beautiful orange blossoms. To anyone who has not seen this tree in its native soil (North America) a visit would amply repay.—*Chas. Dundas Everett*, in "Field."

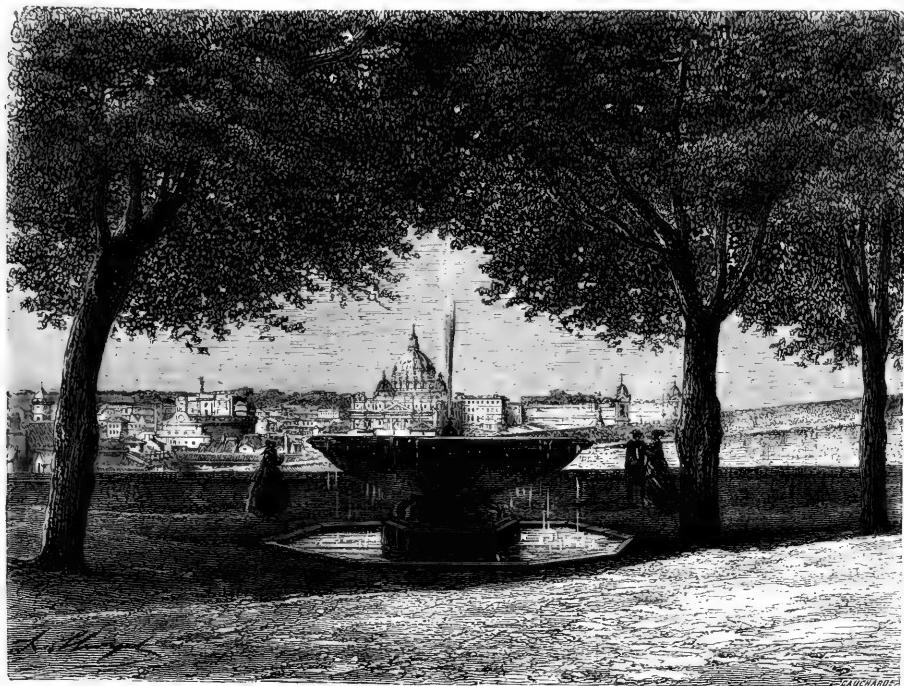

PUBLIC GARDENS.

THE GARDENS OF THE PINCIO, ROME.

N the brow of the Pincian Hill are the public gardens, with their carriage drives and shady promenades, which form a very favourite resort of the inhabitants of modern Rome. These pleasant walks and drives are due to the taste and energy of the French during their occupation of Rome in the time of the first French Republic, about the year 1790. Previously to that epoch, the present Piazza del Popolo, which still preserves in its name its republican origin, was an irregular and comparatively waste piece of ground; while the Pincian Hill, which rises on its eastern side, was utterly bare, with the exception of a few somewhat squalid tenements, which were swept away at the time that these unpromising sites

resort of the Roman population, but is also much frequented by foreign visitors, on account of its being so near to the great hotels of the Piazza del Popolo and the Piazza de Spagna. It is indeed very often the first point a visitor rushes to, five minutes after his arrival, because, from the level of the upper terrace, a magnificent view of St. Peter's is obtained, as represented in the annexed engraving.

The first glimpse of the vast fabric of the great Roman cathedral has long been deemed one of the chief sensations of European travel. Madame de Staél described with enthusiasm the shouts raised by her postillions at the point of the road from Florence, where the form of the great dome is first seen looming, vast and dim, on the blue horizon. But far more impressive is its aspect, especially at time of sunset, from the Pincian Hill, whence it is seen rising against the sky in the golden haze of those cloudless Italian evenings, which so rapidly pass through their brief twilight into darkness. St. Peter's is never seen to greater advantage than from the Pincio at that hour, the fountains and foliage of the garden promenades making a noble foreground to the more distant part of the picture.

View from the Pincian Hill Gardens, Rome.

were converted into a picturesque garden and a handsome public square. The approach to the summit of the Pincio is made easy to carriages by means of inclined terraces, which form a very successful example of the manner in which a precipitous hill may be turned to account, and rendered easily accessible either for a public garden or for any other purpose. The hard lines of the architectural walls of this series of rising roads are agreeably broken by rose-flowered Robinias, at short distances; which are kept closely cropped to a certain height, in order to preserve their harmony with the architectural features with which they are associated.

This charming promenade-garden is not only a favourite

From other points of the Pincio, far more extensive views of the city are obtained, and few visitors fail to remark, as a salient feature, the ancient column of the Antonines, one of the most marvellous monuments of Roman sculpture, which towers above the modern houses, as the glance of the spectator travels along the line of roofs formed by the palaces of the Corso. Another object, and one of no less interest, is visible from the opposite side of the Pincian Hill, one that lovers of art linger long to look upon—it is the casino of Raphael, the dwelling in which many of his finest easel pictures were painted.

Though the merit of planning and planting this noble public

promenade has little to do, in a horticultural point of view, with the surrounding associations, it must yet be conceded to the planners of it, and to all other successful planners of public parks and gardens, that the selection of a site is one of the chief points to be considered in the creation of a public promenade of this kind. It is not always, however, that a desirable site can be obtained, and in such cases a bad one is better than none, for the healthgiving and civilising effects of public gardens are so valuable and so important, that, where interesting spots are not available, one without adventitious interest must be accepted; for a garden—yes, a beautiful garden, may be made almost anywhere, with the requisite amount of taste and skill. It happened fortunately for the French planners of the Pincian Gardens that a spot combining natural beauty with historic interest lay vacant and ready to their hands, and they had the good taste to avail themselves of it.

The trees of the Pincian plantations have thriven wonderfully, and, with their stalwart growth during three quarters of a century, have formed such umbrageous bowers and such deeply shaded walks, as in the sunny South are beyond price. The available space on the northern level of the hill on which the gardens were devised was of very limited extent, and consequently the laying-out was necessarily of the simplest kind—a few rectangular alleys, a carriage-drive round the external boundary, and a few open spaces for flowers, fountains, and the display of gardenesque statuary being all that it was possible to accomplish. That which was possible was nevertheless exceedingly well done, and few great cities can boast a more agreeable garden-park, on a small scale, than that of the Monte Pincio at Rome.

H. N. H.

THE KITCHEN GARDEN.

THE CUCUMBER.—ITS CULTIVATION AND USES.

(Continued from p. 576.)

ANOTHER KIND OF HOT BED.

ONE of the most successful growers of frame Cucumbers, the late Mr. Barnes, of the Camden Nursery, Camberwell, used to prepare his beds in a rather singular manner, and always attained the best results. Instead of forming a bed of solid dung, as before advised, he used to build up a foundation three to four feet high of refuse timber, branches, and faggots, in fact anything that came to hand, packed closely together, and of sufficient size for the frame to be used. On the top of this foundation a foot or so of prepared dung was placed, and then the whole was surrounded by a dung lining which, thatched with clean straw and protected by the framework before referred to, had not only a very neat appearance, but retained the heat for a long time. The advantage of this arrangement is not only that it prevents over heating at the centre, as is sometimes the case with the dung bed, but it also offers the certainty of increasing the heat at any time throughout the frame by renewing the linings. The success attending this form of bed, as exhibited by Mr. Barnes's practice, was as complete as could be desired, so much so that we consider the plan decidedly preferable to the bed of solid dung. A framework of this kind once formed may stand for years, and merely requires the lining to be applied when fresh heat is required.

THE CUCUMBER IN BRICK PITS.

These are of various constructions, that of M'Phail being perhaps as good as any. It is formed in the following manner:—The foundation being put in of suitable size—say six feet wide, and of any desired length—single or four-and-a-half inch brickwork built in cement is carried up in what is called chequered or pigeon-hole work, to the height of three feet all round, and then the walls are finished solidly to the height which it may be considered necessary to carry them—say five feet six inches at the back and four feet at the front, so as to give a good slope to the sun. Then inside, four inches from the outer wall and parallel with it, a solid wall of brick on edge must be constructed, carrying it to within one foot of the top of the outer walls, and then covering it with thin flooring tiles, so as to make the flue quite steam-tight. Sometimes cross

flues, six inches wide and two feet high, are constructed under each rafter, these too being built brick on edge. This is not a bad plan, as it facilitates the admission of heat to the centre of the pit. The advantage of this arrangement is, that beyond the small quantity of prepared dung necessary to fill the inside to the soil level, the other may be used fresh from the stable; indeed, where brick pits and dung beds are also used, the linings of the former may be considered as the preparatory state of the material for dung beds, and hence there is no useless waste of labour. Where good sweet leaves can be had, the pit may be filled with them, a lining applied outside, and in a few days the pit is fit for work. Pits of this kind are always the best sunk two or three feet below the level of the surrounding soil, the lining space being walled round two to two feet six inches wide. Take also the precaution to have at the lowest point of the lining space a small tank to receive the draining of the dung, as that will be found useful either to return to the lining when it requires to be remoistened, or to enrich the garden ground. A tank of this kind may be readily extemporised by sinking a large oil cask outside the pit. Other materials as well as dung and leaves may be used for heat inside the pit, and for that purpose there is nothing better than spent hops, such as may be procured from the brewers. These retain a mild, wholesome heat for a long time, and when decayed, are not objected to by the roots of the plants. Another material extensively used where it can be procured for bottom heat is bobbin chips, that is the small chips obtained from bobbins made for winding cotton and for other uses. These, however, it is necessary should be made of soft home-grown wood, such as lime, sycamore, horse-chestnut, &c., and for the purpose of generating heat it is necessary the chips should be in a state of slow decomposition, and chips containing resin and tannic acid—those from foreign timber and oak—do not ferment except in very large quantities. Bobbin chips of the right kind must not be used fresh from the lathe; it is necessary that they should be moistened, placed in a heap, and frequently turned until fermentation sets in. Then they may be moistened and put in the pit, and a layer two feet thick will give a fine growing temperature for several months, and then if a little fresh material is added, and the whole watered and mixed together, fermentation will again go on for a long time—in fact bobbin chips where they can be procured cheaply are the best material that can be used for bottom heat. We cannot close these remarks without mentioning tan as a cheap method of producing bottom heat. Where it can be procured without the cost of carting it from a distance it is a certain method of producing heat, but it has the objection of being valueless as a manure, and very liable to generate worms, which are a great nuisance among the roots of plants, and especially injurious to those of the Cucumber.

THE FRENCH SYSTEM OF MAKING HOT BEDS.

Before concluding our remarks upon hot beds it may not be out of place to mention that our French friends in horticulture make their hot beds upon a plan entirely different from that practised here. They do not make up a bed for a single frame or a range of frames, but the commercial gardeners collect a large quantity of material—manure, leaves, garden refuse, weeds, &c., and having mixed and left it to ferment for a time, as soon as it is in a fit state, they form it into one large bed, twenty to fifty feet square, and then cover it with frames, just leaving sufficient room between each range of frames to get between them to perform the necessary work of cultivation. The beds are made of the depth necessary to give the desired temperature, three to four feet, and they present the following advantages: First, a large mass of fermenting material in a state of slow decomposition; second, a very small space exposed to the cooling effects of atmospheric changes, merely the pathway between the frames; and, thirdly, economy of material, inasmuch as the dung necessary for a two-light frame with us, would be sufficient for a three-light one on the French plan. The drawback is that of inability to replenish the heat when the first supply becomes exhausted, and no linings can be applied. Still, as a means of growing a summer crop the plan is worth following, especially for market purposes. A bed twelve feet wide might be made facing east and west; upon this two ranges of frames might be fixed back to

back and close together, and upon such a bed it is fair to infer crops of either Cucumbers or Melons, or in fact any other crop requiring bottom heat, might be grown with a certainty of success.

(To be continued.)

THINNING THE SHOOTS OF POTATOES.

The late frosts have in many places cut down early potatoes to the ground. Where this has happened a complete thicket of shoots is now springing up, and if all of them are allowed to remain, the crop may be heavy, but the tubers will certainly be small. The best plan is to go over them at once, and thin out the shoots by pulling them up with the hand; leaving one, or at the most only two stems to each root, retaining, of course, the strongest ones. This will not only conduce to the excellence of the tubers, but, what is, perhaps, of equal importance, will render them fit for digging at least a week earlier than they otherwise would be. Many good cultivators before planting their potatoes, reduce the number of eyes by cutting them out, leaving the strongest one on the crown of the potato. The advantages claimed are, a more even-sized crop and earlier maturity. By reducing the number of shoots, sun and air will be admitted more freely among such as are left; the growth will be sturdier, and they will be better able to resist disease. I have observed for years, when potato digging has been going on, that whenever the digger came to a root with only one stem, the produce was invariably finer and more even in size than where there were many shoots. Time is found to thin mangolds and turnips, then why not potatoes? The two cases, it is true, may not be exactly analogous, but the principle of concentrating the producing power is similar. At all events, I am convinced that anyone giving the plan a trial will be satisfied with the result.

E. HOBDAY.

TOMATOES.

The Solanum family generally is not a very edible one, indeed often markedly poisonous; but we manage to get some very good things out of it notwithstanding. There are, for instance, the potato, the egg-apple, the many kinds of capsicum, the tobacco, the Solanum anthropophagorum, or cannibal's tomato, which the natives of the Fiji Islands use with their cold missionary; and, finally, we have the tomato, which is, in our opinion, the one of the family—bearing in mind our opportunities of cultivating it—which is not sufficiently known or appreciated amongst us. Of course, it is largely used and grown in many places in this country, and yet but to a limited degree, considering its merits. There are very few houses or gardens where bare spaces along the lower parts of fruit walls, &c., may not be found to grow a good crop. In the south of England it may be grown well away from walls on sunny borders, &c.; and in the colder parts of the north the frames, pits, &c., that are emptied of bedding plants in the summer months will grow it to the greatest perfection; while everywhere the plant may be grown with the greatest ease in pots. Some of the new varieties would seem to be well worthy of pot culture, from their pretty and distinct character, and even in places where the plant may be grown with ease in the open air. To tomatoes, then, knowledge of the best way to employ them, we wish wide popularity. Many of the under-mentioned varieties are curious and distinct; they come chiefly from America, where the tomato is enjoyed to a degree unknown in this or any European country. The following is Mr. Barron's description of the varieties:—

The earliest variety is the Red Cherry (syn. Cherry-formed), the fruits of which are round, red, about the size of cherries, and borne in clusters of from six to ten fruits in great abundance. It forms a very handsome plant. The Yellow Cherry (syn. Small Yellow) is the same as the Red Cherry, except that the fruits are yellow.

The Pear-formed (syn. Pear-shaped) has the fruits from 1½ inch to 2 inches in length, red, of the form of a small pear, and borne in clusters, in great abundance. It is very handsome.

The Yellow Plum (syn. Plum-formed) has the fruits small, yellow, oval in shape like a damson, and very handsome.

The Round Red (syn. Extra Early Red, and Sim's Mammoth) is a few days later than the foregoing; the fruits are red, roundish, ovate, and smooth, about the size of a Washington plum. It is very prolific.

The Large Red Italian (syn. Orangefield) is the earliest of the large-fruited sorts; it is very dwarf and prolific, bearing fine fruit within six inches of the ground. The fruits are very large, red, corrugated or ribbed. It is an excellent variety, and one of the best in the collection.

Kaye's Early Prolific is a tall-growing variety, with the leaves

much more entire, and of a lighter colour, than in any of the other sorts. The fruit is medium-sized, pale red, corrugated, somewhat later than the Orangefield, and very productive. It is altogether a first-class variety.

The Grosse Rouge Hâtive of Vilmorin is later than the Large Red Italian, and a stronger grower, but a fine and true variety.

The Filden (syn. Red Valencia Cluster, New Giant) is a strong-growing variety, much praised in America. The leaves are deep green. It is late, and not so prolific as the others.

The Large yellow is the same as the Common Large Red, except that it has yellow fruits.

The Tomato de Layo (syn. Grenier, Upright or Tree Tomato) is of a stiff erect habit of growth, and will stand without stakes. The leaves are deep green, and the fruits are large and slightly corrugated; but it is very late, and not suited for cultivation in this country, excepting in exceptionally warm seasons.

The Great Mammoth of Barr & Sugden, or Large Red of Thorburn, has smaller and more finely cut leaves, with the fruits very similar to those of Gross Rouge Hâtive. The Large Red of Veitch is synonymous with Powell's Prolific. The fruits are medium-sized, roundish, and slightly corrugated, and the plants very prolific. The Filden of Thorburn, or Red Valencia Cluster, is a strong-growing variety, which appears to be very highly esteemed in America. The fruits are large, full, roundish, slightly corrugated near to the stalk only, of a deep red colour, and the leaves are deep green; it is rather late, and not so prolific as others, but very excellent. The Fiji Island, or Lester's Perfected of Thorburn, is very similar in all its characters to the Filden, excepting that its fruits are of a decided crimson, quite a distinct colour among tomatoes. The fruits are large and very fine, both of this and of the preceding variety.

The finest variety raised for a long time, and one that is generally allowed to be a great improvement, is Trophy, an American variety.

LIME A CURE FOR THE POTATO DISEASE.

Some years ago—I think it was in 1857—I saw several experiments tried, both for the prevention and cure of the potato disease. In a field of potatoes several rows were planted in the ordinary manner, and left to themselves without anything else being done beyond earthing up; the same number of rows had lime put over the tubers or sets at the time of planting, and a similar number were planted in the ordinary manner, and soon after coming through the ground had slaked lime dusted over their tops, and again repeated when they were earthed up. I was present when they were lifted, and the following are the results:—The first lot were half diseased, the second not much better, whilst in the third there was not a diseased tuber to be found. I believe the potato disease is caused by sudden changes of the atmosphere, and generally appears after a heavy thunderstorm, when the earth is suddenly changed from a warm and genial temperature to a damp and cold one; that is the time, in my opinion, when the disease attacks the haulm and works its way down the stem into the tubers. The next year I tried the liming process in my own garden on a small scale. Where I was living, in Suffolk, there were two cottages, the gardens of which were divided by a line of box about a foot high. I planted three parts of my garden with early Shaws and a few of the newer sorts. My neighbour did the same. At the time of my second operation of "liming" he had a good hearty laugh at me, and well he might, for I was as white as a miller's man; but at taking up his part it was my turn to laugh, for my potatoes were all *good*, and his three parts *bad*.

Liming or dusting with lime is easily performed; choose a dewy morning, and putting on an old coat and apron, carry a box of lime in one hand, and scatter it with the other.—R. H. BARD, *Wellington Nursery, St. John's Wood.*

Tomato Culture.—The great secret is in pinching off the head continually above the bunch of fruit. This pinching is continued throughout the season. On the above management they may be grown against ridges in this way, or even staked up if the situation is warm. My principal object is to encourage the cottager to grow this plant for his own consumption. Now, before I found out the simple way of making the plant bear a heavy crop, I dared not have any confidence in the plant, and was always anxious about it, for this plant, if allowed to grow anyhow, is the most barren of any plant I know of; and when fruit is produced half of it never ripens at all.

Fertilizing Melons and Cucumbers.—The artificial fertilisation of the female flowers of Cucumbers and Melons constitutes a most important article of faith among practical horticulturists. The "setting" of the crop by hand is insisted on in all garden calendars; if it is not necessary, the immense amount of time consumed thereby is wasted. In the thousands of gardens where handsome and well-flavoured fruit is everything, and seed of no consequence at all, we have thought that the best way to secure a good crop is to manage to secure for our own use for many years past cucumbers and melons in sufficient plenty, without putting ourselves to the trouble of applying the pollen, and have long since been satisfied that, except for the production of seed it is labour wasted.—*Gardeners' Magazine.*

GARDEN DESTROYERS.

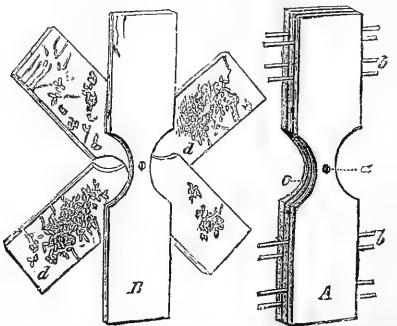

AN APPLE WORM TRAP.

The Americans, long pestered with this hateful "worm," have paid it much attention, and have devised some sagacious schemes for its destruction. To one of the best of these we now desire to call attention. It is thus described by Mr. Riley in the *American Agriculturist*—

Mr. Thomas Wier, of Lacon, Illinois, has hit upon a simple device for alluring apple-worms, which is destined to play an important part in counterworking their injuries. In conjunction with his cousin, he has patented his trap, and though I do not think that the patenting of such simple devices is quite in accordance with a progressive horticultural spirit, or that the patentees will find it a very profitable undertaking, they have a perfect right to think otherwise. It was too late in the season when the trap was brought to my notice to give it a thorough trial, but I was at once favourably impressed with its usefulness; and what little I have seen of its work has not altered that impression.

The trap (see figure—*A* closed, *B* open) consists of two, three, or more thin pieces of board, twelve to twenty inches in length, and two to four inches wide, with a screw (*a*) through their centre. The screw must be long enough to be firmly driven into the trunk of the tree, so as to hold the boards in position. The boards are cut out on each side of the screw, as at *c*, to facilitate their separation when fastened together by the silken threads of the worms, and to better expose the latter when the trap is opened.

The advantages of this trap so far outweigh the disadvantages, that it may be considered the best we yet have. These advantages

Apple Worm Trap.

may be stated as follows:—It is cheap, accessible to all, easily placed on the tree and removed again; wood forms, perhaps, the most natural covert for the worms; the traps may be collected with little trouble, by the barrowful, submitted to a killing heat, in one way or another, and replaced again; they may be used on the ground as well as on the tree. Its disadvantages are few. One it has, in common with all other snares or traps for this insect, namely, that it can never exterminate the Codling moth, for many reasons that will suggest themselves to all who have any acquaintance with the insect. Another is, that where one trap only is used it can be attached to but one side of the tree, and in this single respect, notwithstanding all the theories of my friend Wier, it must always be inferior to any trap that encircles the tree.

The worms will spin their cocoons between the inner shingle and the tree as freely as between the shingles themselves, and I suspect that it will be found less tedious and cheaper to detach the traps and kill the worms by wholesale, than to open them on the tree. Concerning the latter method, Mr. Wier says:—"The quickest and best way is to have a large tin pan bent in one side, so as to fit closely to the trunk of the tree. When you reach the tree, drop upon your knees, place the depression in the pan against the trunk of the tree, hold it there by pressing your body against it, and you have both hands free to open the trap. When opening it, many of the pupae or chrysalids will fall into the pan, and some of the worms. Kill the rest or scrape them into the pan. The trap must be turned clear around, as many will be found between it and the bark. A person will open and kill the worms in from four hundred to eight

hundred traps in a day." I have known one of these traps to be so thoroughly torn to pieces by the Downy Woodpecker, that if they are to be preserved from year to year, it would be dangerous to leave them on the tree during winter. The inventor informed me that he believes his trap is more apt to come into general use by being patented, than if offered without price to the public. The danger is, that patentees are sure to claim too much for their pet creations. This fact is well exemplified in the present instance, for the label pasted on such of the traps as have been so far sent out, commences as follows:—"Thomas Wier's apple-worm and curculio trap, which catches apple-worms, curculio, and every species of insects infesting fruit."

The love of gain obscures the light of truth; and this wonderful power of a pair of shingles to catch "every species of insect infesting fruit" is altogether too much like Mr. Quackenbush's patent universal, never-failing elixir, which cures all diseases that possess mankind. Other evils will likewise result from the sale of this trap under such spurious claims, and without some explanation of the insects' habits. One of them may be illustrated by the following dialogue, which is not altogether imaginary, but is founded on an actual occurrence. Agent Gaingread—his desire to sell rights being stronger than his love of accuracy—meets farmer Glanball, and straightway expatiates upon the merits of the patent trap. He shows how the worms gnaw their way in between the shingles, and how easily they may be destroyed. "Ach!" cries the credulous German, "und is it true das de worm rader eat du schindel dan du apfel?" "Oh, yes!" says Gaingread, "scrree one of the traps on to this tree, and in a week I will come back, and we will examine it." At the expiration of the week the trap is opened, and upon viewing with wonder the worms that have secreted in it, Glanball rapturously exclaims, "Ist es möglich? das is de best ting I yet see," and purchases the right to use much quicker than he would if he knew that the worms had already been in his apples.

I have thus indicated the mischief that may be done by over-estimating the value of this trap, in order that the patentees may strip it of all appearance of sham, and present it to the fruit-grower for what it is—a useful and important device—and not extol it as a sure Codling-moth exterminator.

THE GARDENS OF ENGLAND.

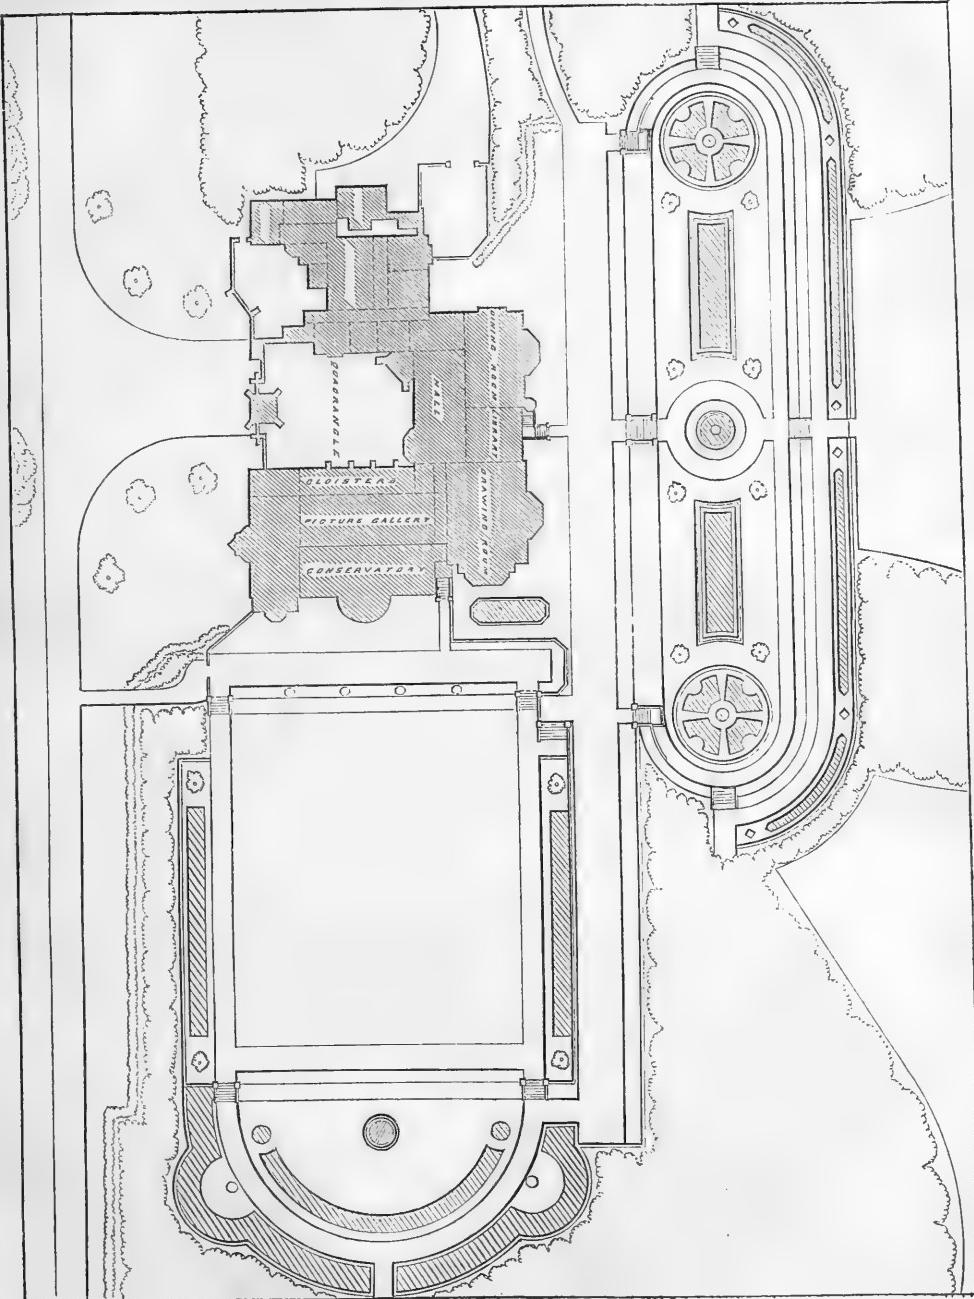

THE TERRACE GARDEN AT POSSINGWORTH.

Possingworth, in Sussex, the seat of Mr. Louis Huth, as recently laid out by Mr. Marnock, promises to be a noble place when its many plantations have attained to a ripe age, and when the finishing touch of Time has been given to the margin of its fine expanse of artificial water and its many other fine features. To some of these we may again advert, and now merely say a few words to introduce the terrace garden and immediate surroundings of the house to our readers.

The terrace garden at Possingworth differs from most of its kind in the absence of the numerous geometrical figures and beds usually considered indispensable to the style. When at Possingworth in the autumn we were struck with the good effect of the few but rather large masses of flowers in front of the house and the great pleasant spread of green to the left.

RYTON HOUSE, RYTON-ON-DUNSMORE.

EUREKA! A small old-fashioned garden, the like of which I began to fear was extinct. Something like it has been described by Mr. Henry Kingsley in "Hornby Mills." So bare were the large gardens in Warwickshire, that I began to feel I was no longer in a land of spring flowers. Here is a little oasis of them. A lawn green as tufts of the mossy saxifrage on the 1st of November spreads from the back of the house to a belt of surrounding trees. The abominable orthodox little terrace-garden of the ordinary landscape gardener does not violate the carpet of verdure that rolls to the steps of the verandah; nothing disturbs the repose of the sweet foreground, and the eye rests in peace on the deciduous and other pines with which the lawn is adorned. So far nothing remarkable by way of improvement, except the abolition of formal spaces of bare earth. To the right and left, a little in the distance, a gay little crop of varied blooms is soon peeping over the emerald grass. These are the May bloomers of a very interesting collection of hardy flowers arranged in mixed borders. The earth here is not, as usual with much of our garden beds and borders nowadays, less interesting than the adjoining meadow, for here is the fair little St. Bruno's Lily, which just now is opening its pale green-tipped trumpets on many a

PLAN OF THE TERRACE GARDEN AT POSSINGWORTH.

wide waving sea of meadow grass just below the receding snow in the valleys of Piedmont; here, too, are some of our own rarer wildlings, like the Creeping Gromwell (*Lithospermum purpureo-crecum*), which is quite wild and full of deep purple bloom on the little rockery; here the Dog's-tooth Violet, the Snowy Crowfoot, the Alpine *Erinus*; little shrubs eighteen inches high of the tree Linum (*L. arboreum*), flakes of the alpine Phloxes of the Rocky Mountains; healthy plantations of the old double primroses, now become so scarce; stately tufts of Globe flowers, and blue dots of Gentian; wide edgings of Mountain Cat's-foot, bestrewn with its dull crimson little "everlastings" flowers; summer Snow Flakes, beginning to open in Mayfall showers; tufts of Adonis, with its last great yellow stars; rich golden Welsh Poppies, as well established as they are by the roadways near Wimdermere; sheets of the wood Forget-me-Not, and of the Mountain Avens, running over the rocks with its crowds of white, yellow-stamened bloom, with many of their fair companions passing out of and coming into bloom.

Let us pass away from the garden, and into a small wood partly surrounding the place. It is a rather dense grassy plantation with a little green walk winding through the trees and by the margin of a small lake. Through the weeds and long grass bold Lilies are pushing up nearly ready to flower. Tufts of the Poet's Narcissus are already in bloom in this pleasant wilderness. The large-flowered Everlasting Pea is tangled through the low bushes all carelessly and wild like the rest; but here, in an open spot, is a tuft of Acanthus, evidently recently and carefully planted; and the pleasant fact is seen that the plants here are no chance outcasts from the garden, but carefully planted by loving hands. It is, in fact, a wild garden we are wandering through, and in which, quite at home, exotic Irises and Daffodils flourish in the domain of the Solomon's Seal and the Periwinkles. Such is a glimpse of this charming garden, as far as I can feebly express its beauty. But as—

"When spring herself is here, in vain we look
To find her likeness pictured in a book."

so is it exceedingly difficult to describe on paper the early summer loveliness of such a garden.

It is impossible to avoid drawing comparisons between this garden and others, and the comparisons are wholly in its favour as compared with the ordinary type of villa garden. That it enjoys a long season of beauty before people begin to think of covering the brown earth with their bedding plants, is proof enough of this, and that season is the most delightful of the year. But let no one suppose that such a garden offers us the only alternative with the bedding system. There are many other ways in which we may vary and beautify our gardens as well. Besides, the bedding system itself must ever be, when properly arranged, one of the most beautiful ways of growing plants. There is no reason whatever why what are called bedding plants should not be arranged in as true and beautiful a way as any others. Nevertheless, I was charmed to see what was the result here of depending on hardy flowers alone. There was not, so far as I could see, a single bed in the place destined to receive bedding plants; yet the garden was full of beauty and interest, and evidently had been so for the past three months. Be it observed, however, that much of the good effect would have been spoiled if the foreground of the picture—the untortured little lawn, with its trees—had been broken up by geometrical patterns.

This garden is the property of Miss Freeman, whom I had not the good fortune to find at home, or perhaps I might have discovered more beauties than I had the pleasure of seeing. For kindly guidance to it, as well as to many of the gardens of Warwickshire, I am indebted to Mr. William Miller, of Combe Abbey.

THE COVENTRY CEMETERY.

It was a good idea that of making our cemeteries suburban gardens, which was carried into effect in this country, and more extensively in America, when burying closely in towns was discontinued. Rarely, however, does one meet with such a happy illustration of the result as is now given by the Coventry Cemetery. This is an ornamental garden in a very high sense. It is not only with our dreary old town cemeteries that such an oasis contrasts in beauty. The country graveyards, many of which offer the most inviting positions for hardy plants, and all of which could be easily converted into beautiful gardens with very little trouble or expense, are, for the most part, as devoid of any grace as a barrack-yard. There is no need why this should be so; only a Vandal would recommend that these hallowed spots should be embellished in any sense like what is called a "modern flower garden." It were better they should lie fallow for ever, than that any such blight should fall upon them. But much might be done to make them more beautiful, without in any sense violating their character or the fitness of things. They invariably offer sites for a few beautiful trees; and

never was country so rich in weeping and other highly-suitable trees as ours is now. Yet you may go for days through villages without seeing an attempt at planting. Then the walls! What a difference between an old church draped with ivy, clematis, and Virginian creeper, and the like, and one as bare as a new factory wall! It is with churches as with cottages; they are generally pleasing in proportion to the degree in which their walls are covered with vegetation. Here, again, we have no end of almost unused wealth; some of which, like the ivies and the new Japan creeper (*Ampelopsis tricuspidata*), do not even require training over the walls, but hold on with their own rootlet-fingers. The ivies, in their now numerous and beautiful varieties, give us all we want for the embellishment of our churches and churchyard walls, which are often bare of all life except seams of moss sown by the wind.

The Coventry Cemetery is very agreeably and boldly diversified. It abounds with stately and beautiful tree-life, much of it evergreen. The planting is quite superior to that usually seen in what are considered the best gardens. Near the entrance stands a tall and not ungraceful monument to the designer of the cemetery, and for years member for the city, the late Sir Joseph Paxton. Most fitting is it that the city of the dead should be embellished with such life as here springs from the turf. If we make our cemeteries combinations of a graceful garden and arboretum, such as this is, we throw a charm round the brink of the grave itself. The total absence of bare earth here gives the place a refreshing look, too rare in gardens. The well-broken easy margins of the plantations also deprive the place of the disagreeable air imparted by formal margins. Fortunately, almost every one of our fine evergreens thrives in perfection here, from the hemlock to the Wellingtonia. The hemlock is a peculiarly graceful cemetery tree; the red cedar should be more employed for cemetery planting, especially where other tapering trees do not succeed owing to the cold.

The place is in admirable order, and reflects much credit on the superintendent, Mr. Dawson, and on the town. One important improvement might, however, be made by embellishing the place liberally with spring and early summer flowers. This could be done without any formal or expensive gardening in beds, by merely dotting the plants or seeds about in the margins of the extensive shrubberies, &c. It may be objected that these would be destroyed by the visitors to such places, but the objection is a groundless one. As instances of the spring flowers which may be naturalised in such a place, and which would add to it many charms in spring, I may mention the Apennine anemone, the Geneva bugle, the Japan and snowdrop anemone (*A. sylvestris*), snowdrops and crocuses, the winter aconite, the snake's head, hepaticas, snowflakes, lilies, honesty, grape hyacinths, forget-me-nots, daffodils, *Omphalodes* verna, bluebells, and violets.

There is one great eyesore here which interferes sadly with the beauty of the scene. It results from the mutilation of a great number of weeping limes. These were planted in abundance all over the cemetery; in one place they border a winding avenue. Some years ago these trees (they are all strong and vigorous specimens), were pollarded! Yes, all the limbs and branchlets, which constitute the charm of every weeping tree, were lopped off close to the main lower branches. It would not be easy to find a sadder sight among trees, than those presented on the 9th of May. What their summer aspect may be, I know not, but it is most unwise to disfigure a fair scene like this by such monstrosities, even if they were only seen for a week in the year. Want of room is said to have been the reason for mutilating them. Surely, it would have been better to remove all for which there was no room, than make tree-scarcrows of them. I never saw anything uglier than the avenue of these weeping limes in this cemetery in their winter dress. If this were altered, I know of nothing of the kind, which, for its size equals in picturesque beauty and in the richness of its tree flora the Coventry Cemetery.

Maidstone Public Garden.—The work of laying out the public garden to be presented to the town of Maidstone by Mr. Julius Brenchley, nearly approaches completion. About five acres of an old apple orchard adjoining the private garden at Chillington House have been converted into a picturesque garden, in the centre of the town, from all parts of which it will be easily accessible.

The Garden.—A garden is a beautiful book, writ by the finger of God: every flower and every leaf is a letter. You have only to learn them—and he is a poor dunce that cannot, if he will, do that—to learn them and join them, and then to go on reading and reading. And you will find yourself carried away from the earth by the beautiful story you are going through. You do not know what beautiful thoughts grow out of the ground, and seem to talk to a man. And then there are some flowers that seem to me like overfull children: tend them but ever so little, and they come up and flourish, and show, as I may say, their bright and happy faces to you.—*Douglas Jerrold*.

THE PROPAGATOR.

SOFT-WOODED PLANTS IN SAND AND WATER.

MR. WM. GARDENER's mode of striking cuttings of soft-wooded plants (see p. 481) is quite right with the exception of two things, first; after inserting the cuttings, he says, "fill up with water;" secondly, he recommends the same pans of sand to be refilled with fresh cuttings. Now, in the first case, if the sand is too wet, the cuttings, especially Verbenas, will curl up, and the base of the cutting will come out on the top of the sand. Fresh sand should always be used, as I find that the second batch in the same sand never strikes so readily. I thank Mr. Gardener for bringing forward the subject, for though I have practised a similar mode of striking soft-wooded things for fifteen years, I have never seen anything respecting it in print before. My mode of proceeding is this: first, I make my cuttings, keeping account how many I have got as I go on. Next, I fill pans with sand level with the top, and sprinkle them with water through a fine rose to consolidate the sand. Then if I have, say a hundred cuttings, I proceed to insert them with the end of a small quill, than which nothing is better, say fifty in a twenty-four sized pan, more or less according to circumstances; another sprinkling of water through a rose settles the sand firmly down about them, and the work is finished. The sand should never be allowed to get dry, nor should it ever be made the least sloppy. A nice brick-dung bed and frame is the best place in which the pans can be set. I use a small-one light frame for the purpose, with a two-light frame to receive them when potted off. The old sand when dry is employed for general bench purposes, but in no case do I use the same pans or sand again, unless well washed.

Guildersfield, Streatham Common.

WM. WILLE.

THE ART OF GRAFTING.

(Continued from page 575.)

TREATMENT AFTER SIDE-GRAFTING UNDER THE BARK.—In grafting with a dormant eye, with a view to propagation, the particular treatment will consist in heading down the stock, after winter, to four inches above the graft, and immediately tying up quite erect the top of the woody scion, in order to avoid a knee or bend at the graft. The first process (with a simple branch) when employed for purposes of restoration, does not require the amputation of the stock; but in order to hasten the development of the graft, a notch is cut in the stock, about a quarter of an inch above the graft, in spring. The notch, in form of a crescent, about half an inch broad, is made with two cuts of the pruning-knife in the bark. An example of a similar operation has already been given. At the same time the branches above the graft are pruned short. A thin stake is indispensable for fastening up the young graft. When the grafting is made with a shooting bud, at the flow of the sap, the scion should be covered with grafting-clay, to preserve it from the sun and the scorching winds. If, notwithstanding its speedy vegetation, it exhibits a tendency to remain puny, its growth may be accelerated by making small longitudinal incisions. By cutting the bark the sap is induced to

flow more freely under the dilated surface, and causes the branch to increase in thickness.

SIDE-GRAFTING IN THE ALBURNUM. GENERAL DIRECTIONS.—This method is more specially adapted for evergreens; therefore it is more frequently adopted for grafting under glass, the season for which is in February and in August. If the same kinds are to be grafted in the open air, it should be done in April and in August. For evergreen scions, a branch of medium size, and furnished with a terminal bud, is to be preferred. It is to be

cut from the tree at the moment of using it; none of the leaves are to be removed, except those at the base; and to keep it fresh it should be placed in the shade with the end in a vessel of water or in sand. The stock is not headed down, and the leaves on the part destined to receive the scion, are cut off at the stalk or in the middle. In order to insert the scion into the alburnum of the stock, the bark and outside layers of alburnum are removed, directing the blade of the

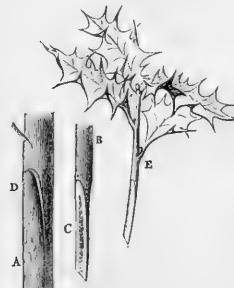

knife from above downwards, taking care not to penetrate to the pith. The scion is cut thin on both sides, if it is to be inserted at the top of the cleft, or cut in a wedge-shape if inserted in the side of the incision. Hence arise the following two subdivisions:—

SIDE-GRAFTING WITH A VERTICAL CUT.—The camellia scion (A) is cut for the half of its length on both sides (a), leaving on each side a strip of bark of equal width, and tapering gradually to the point. The stock (B) is cut as at (b) with one stroke of the grafting-knife, allowing the blade to penetrate as far as the alburnum. The scion (A) is introduced by its base (a), and then bandaged, as shown at C. Should the grafting be done in the open air, grafting-wax

should be applied on both sides of the cleft, so as to fill any vacancies that may occur. With the camellia, and other hard-wooded shrubs, the stock is maintained entire at the time of grafting; but the Aucuba, the tissues of which are less dense, is cut down to within four to eight inches above the graft at the time of the operation.

SIDE-GRAFTING WITH AN OBLIQUE CLEFT.—The scion E is the top of a branch of holly.

The lower part of it is represented at B with a sloping cut (C) on both sides, and with the back of the slant much longer on the outside. An oblique incision (D) is made in the stock (A) by cutting through the bark and alburnum in a slanting direction with reference to the axis of the stock. The scion will thus be inclined at an angle, and its leaves will not be embarrassed by the stock. It may also be placed in an upright position by giving an oblique direction to the sloping cut. It should be bandaged with some elastic material. A certain number of conifers are best grafted with the oblique incision; the wound does not enlarge so much as in the case of the vertical incision, and a slender scion is more securely fixed in it. To the group of side-grafting we might

add the method termed gimlet-grafting, in which a gimlet or drill is used to pierce an oblique hole from above downwards through the bark and albumen without reaching the pith. The mouth of the hole is smoothed, and the end of the graft is cut round and pointed so as to fit it properly. This method is seldom used; it should only be employed on old stocks, which do not exude gum, and when it is required to supply a branch to a very bare stem.

TREATMENT AFTER SIDE-GRAFTING IN THE ALBURNUM.—If the grafting has taken place in the month of April, the head of the stock should be gradually cut away, as soon as the cohesion of the parts seems to be assured, continuing the operation in proportion to the development of the graft. But if the grafting has occurred in autumn, the stock is cut, after winter, to within four to six inches of the graft, preserving on the heel the principal leaves and small branches, which will be removed afterwards when the graft has developed its shoots. The heel, which serves at first as a prop for the young shoot, is to be cut off level with the graft, as soon as the young shoot shall have acquired sufficient strength to maintain itself.—*C. Baltet.*

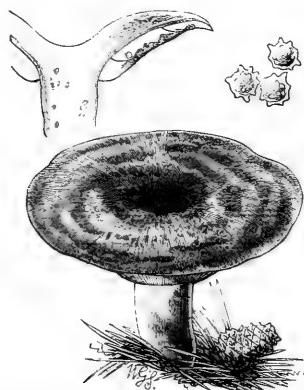

(To be continued.)

THE HOUSEHOLD.

ORANGE-MILK MUSHROOM.

(*Lactarius deliciosus*.)

THERE is no possibility of mistaking this fungus. It is the only one which has orange-red milk, and which turns green when bruised. These properties distinguish it at once from *Lactarius terminosus* or "necator," the only fungus which in any way resembles it. This acrid fungus (*Lactarius terminosus*) is somewhat similar in shape and size, and is also zoned. But the involute edges of the pileus are bearded with close hairs. It is of a much paler colour, and with gills of a dirty white. The milk, also, is white, acrid, and unchangeable in colour. The orange-milk agaric chiefly affects the Scotch fir-tree, and is generally to be found beneath the drip of the branches around the tree. It is also found in hedgerows occasionally, but is most abundant in plantations of Scotch fir or larch.

Orange-milk Mushroom (*Lactarius deliciosus*). Under fir trees, in autumn; colour, brown-orange; milk at first orange, then green; diameter, three to ten inches.

Pileus smooth, fleshy, umbilicate, of a dull rufous orange, turning pallid from exposure to light and air, but zoned with concentric circles of a brighter hue; margin smooth, at first involute, and then becoming expanded; from three to five inches across. Flesh firm, full of orange-red milk, which turns green on exposure to the air, as does any part of the plant when bruised. Gills decurrent, narrow, each dividing into two, three several times from the stem to the edge of the

pileus; of a dull yellow by reflected light, but being translucent, the red milk shines brightly through them. Stem from one to three inches high, slightly bent and tapering downwards; solid, becoming more or less hollow with age; short hairs at the base; sometimes pitted (scrubciliate).

OPINIONS ON THE MERITS OF *LACTARIUS DELICIOSUS* AS AN EDIBLE FUNGUS.—"This is one of the best agarics with which I am acquainted, fully deserving both its name and the estimation in which it is held abroad. It reminds me of tender lambs' kidneys."—DR. BADHAM.

"Very luscious eating, full of rich gravy, with a little of the flavour of mussels."—SOWERBY.

"Cook them well, and you will have something better than kidneys, which they much resemble both in flavour and consistence."—MRS. HUSSEY.

MODES OF COOKING *LACTARIUS DELICIOSUS*.—"The rich gravy it produces is its chief characteristic, and hence it commands itself to make a rich gravy sauce, or as an ingredient in soups. It requires delicate cooking, for, though fleshy, it becomes tough if kept on the fire till the juice is exuded. Baking is perhaps the best process for this agaric to pass through. It should be dressed when fresh and pulpy."—EDWIN LEES.

STEWED DELICIOSUS.—"The tourtière (or pie-dish) method of cooking suits *Lactarius deliciosus* best, as it is firm and crisp in substance. Be careful to use only sound specimens. Reduce them, by cutting across, to one uniform bulk. Place the pieces in a pie-dish, with a little pepper and salt, and a small piece of butter on each side of every slice. Tie a paper over the dish, and bake gently for three-quarters of an hour. Serve them up in the same hot dish."—MRS. HUSSEY.

DELICIOUS PIE.—Pepper and salt slices of the agaric, and place them in layers with thin slices of fresh bacon, until a small pie-dish is full; cover with a crust of pastry or mashed potatoes, and bake gently for three-quarters of an hour. If with potato crust, brown nicely before a quick fire.

DELICIOUS PUDDING.—Cut the agaric into small pieces; add similar pieces of bacon, pepper, and salt, and a little garlic or spice; surround with crust, and boil three-quarters of an hour.

FRIED DELICIOSUS.—Fry in slices, properly seasoned with butter, or bacon and gravy; and serve up hot with sippets of toast. A steak in addition is a great improvement.

How to Make the Most of Coffee.—According to M. Schadler only half the quantity of finely ground coffee is needed, in order to produce the same strength of beverage obtained by the ordinary coarse-ground article. If, after Oriental fashion, the ground coffee is crushed fine in a mortar, only two-fifths of the coarse is needed. Infusion, boiling, or filtering through a bag, all have the same result as regards strength, except that by filtering the aroma of the coffee is preserved.

PRESERVED ORANGE PEEL.—Clean carefully; cut in thin strips; stew in water until the bitterness is extracted; drain off the water, and stew again for half an hour in a syrup of sugar and water, allowing half pint of water and pound of sugar to each pound of peel. Put it aside in jars, and keep it in a cool place. If desired, a little cinnamon and ginger may be stewed with the peel, but it is more delicate cooked simply with sugar. Lemon peel may be prepared in the same manner, either alone or mixed with orange peel. These form pleasant "relishes" eaten with cake or bread, or if chopped finely when prepared they form excellent flavouring for puddings and pies.

POTATOES BOILED OR STEAMED.—It is stated at p. 383 that potatoes become watery from being covered with a weight of water, and that, moreover, the particles are not able to expand and burst into flour. I venture to challenge that assertion. Potato flour is not so easily compressed as all that. I should like to see the pot of water big enough to prevent the potato flour from bursting during the process of boiling. Very little water indeed can enter the potato during the process of cooking; and as for its weight it is virtually inoperative. Potatoes boiled are almost as floury as potatoes steamed, if the boiling has been properly done, and they are better flavoured. This is my argument for boiling the potatoes are sweeter. Does anyone doubt it? then let him try a draught of potato water, and doubt no more. Where does the water pick up that loathsome flavour? Assuredly from the potatoes, in the process of boiling. And the potatoes must needs be the better for the loss, and they are. I thought otherwise at one time, but I am now fully convinced that the best mode of cooking potatoes is boiling them. The mode of boiling given at p. 383 is good. But one water—a liberal supply—with a handful of salt, will finish them in style, without the trouble of several changes.—D. T. FISH.

PROGRESSIVE GARDENING.

BY THOMAS JERROLD.

To the Romans we no doubt owe the elements of the art of gardening. In the time of Pliny, they seem to have carried it to such perfection, that he speaks of a single head of asparagus weighing three pounds, and cabbages so "pampered" that the poor man's table was not large enough to hold them. Whatever progress we may have made towards artistic beauty, I do not think that our kitchen gardening of the present day very greatly surpasses that of our forefathers. Vineyards planted in the third century existed in the eighth and in the twelfth. William of Malmesbury speaks highly of the vineyards then existing in Gloucestershire. In 1512 the Earl of Northumberland kept one gardener; yet, in Scotland gardening seems even then to have progressed more rapidly than in England.

During the early part of the sixteenth century, after the fierce Wars of the Roses, gardening began to occupy attention, as we may infer from the great progress which had been made in this art during the reign of Henry VIII., when the magnificent grounds of Nonsuch were laid out. These contained groves ornamented with trellis work, cabinets of verdure, and walks embowered by trees. In these gardens, in which wealth and invention seem to have been lavished, a concealed fountain is mentioned, which spouted upon all who came within its reach; and this vulgar taste still seems to have prevailed in the reign of Elizabeth, when the gardens of Holland House and Hatfield were laid out in mazes and labyrinths, and with concealed pipes, which deluged in a moment unware visitors. During the succeeding reign, if we may judge from the description of Theobalds, a slightly better taste prevailed. A large square had its walls covered with Phillyreys, and a beautiful *jet d'eau* occupied its centre; the *parterre* had many pleasant walks, part of which were planted on the sides with espaliers, and others were arched all over. At the end, a small mount, called the Mount of Venus, was placed in the midst of a labyrinth.

During the reign of Charles the Second, the gardens at Hampton Court, Chatsworth, and many others, were laid out. But with the accession of William and Mary to the throne, the perverted taste of the Dutch school of ornamentation came into fashion, and our gardens were disfigured by trees, evergreens, and shrubs clipped into vile forms. In this country gardening has always been a favourite art; it was pursued by the monks with a knowledge and a taste perhaps not excelled in our own day, more particularly in regard to the products of the kitchen garden and the orchard; but it received a great check in England by the dissolution of the monasteries. Bacon, during the reign of James the First, had spoken with contempt of the images cut out of Juniper and other evergreens; and after the rage for the Dutch style began to die out, English gardens appear to have begun to have a character peculiarly their own. While the French were clipping trees into fantastic shapes, like the Dutch, until their groves appeared like so many "green trees set upon poles"; and while Maréchal de Biron flanked his garden walks with nine thousand pots of Asters, we strove to dress Nature with a freer and a wilder grace. Bishop Hatchet described his ideal garden as "a large, beautiful lawn, edged with even rows of trees, a flowery meadow, with a stream running by it, a beautiful garden, a belvedere, with rare figures of compositions" &c. Dryden, speaking of gardens, says: "The plan must be great, entire, and every portion—even the least—must have a reference to the whole." But Cradock, according to Southeby, goes further than Dryden, and says: "Gardening, in its highest stage of improvement, is of the nature of an epic poem." Cradock refers rather to the garden Milton describes as the home of our first parents, and to the scene of Acrisea's bower of bliss, than to the Saardon Gardens, where tables and punch bowls were cut out of evergreens, and where an evergreen stag with leafy antlers guarded the walks. Concerning this kind of gardening, Addison has written:—"Our gardens are not so entertaining as those in France and Italy, where we see large tracts of ground covered with an agreeable mixture of garden and forest, which everywhere represents an artificial rudeness much more charming than that neatness and elegance we meet with in those of our own country. Our

British gardeners, on the contrary, instead of humouring nature, love to deviate from her as much as possible. Our trees rise in cones, globes, and pyramids; we see the marks of the scissars upon every plant and bush. For my own part, I would rather look upon a tree in all its luxuriance and diffusion of boughs and branches than when it is thus cut and trimmed into a mathematical figure; and cannot but fancy that an orchard in flower looks infinitely more delightful than all the little labyrinths of the most finished parterre." Pliny thought gardening could not be carried farther than it was in his time; but no year has passed for many a cycle in which something new has not been added to our gardens. Our nosegays, indeed now gathered in British parterres, consist of contributions from every part of the habitable world.

In the culinary department I fear that gardening has not been carried out with a progress so rapid and so marked as that which distinguishes the art in the park, landscape, and pleasure ground. We have many grand kitchen gardens it is true; but few to excel those laid out and tended by those early gardeners, the monks. Cobbett speaks enthusiastically of the kitchen garden at Waverley Abbey, founded by Giffard, and inhabited by the first colony of Cistercian monks who came to this country. He tells us it was the finest situation for a kitchen garden he ever saw, and thus describes it:—"It lay full to the south; of course, it had a high hill to the back of it, and that hill covered with pretty lofty trees. The wall on the north side of the garden was from twelve to fourteen feet high, built partly of flints and partly of the sandstone which is found in abundance in the neighbourhood, and it was about three feet through even at the top. The ground of which the garden consisted had been the sloping foot of a hill, taking in a part of the meadow that came after the hill, and lay between it and the river Wey. A flat of about twenty feet wide had been made on the side of the hill, and at the back of this flat the wall was erected. After the flat, towards the south, began the slope, which grew more and more moist as it approached the river. At the foot of the garden there ran a rivulet, coming from a fish pond, and at a little distance from that emptying itself into the river. The hill itself was a bed of sand; therefore, the flat—at the back of which the north wall stood, that is to say, the wall on the north side of the garden—must have been made ground. The slope must have been partly made, otherwise it would have been too sandy."

New flowers, new trees, we hear of constantly, but a novelty in kitchen-garden produce is seldom introduced. This may be owing as much to want of purchasers as to the want of enterprise; when a new esculent appears, only such epicures as Fin-Bec become purchasers; the housewife of the middle class is afraid of innovations, she contents herself with that to which she has been accustomed; and the same annual routine of vegetables, cooked in the same old manner, makes its appearance on the dinner-table.

The French, who, to some extent, excel us in the cultivation of fruits and vegetables, have certainly not surpassed us in laying out grounds, or as it is more popularly termed, "landscape gardening." May not this same natural style of gardening which we now possess have had its origin in the simple taste first evinced in early English gardens, which are described in the "Harleian Miscellany," as usually walks of sand made perfectly level by rolling them, and between the walks are smooth grass plots covered with the greenest turf, without any other ornament? How easy the transition from turf to a few trees; then to a group; and, lastly, to flowering shrubs and plants in the foreground!

In our progress from the Dutch or formal school of gardening to the graceful freedom of Kent's style, no doubt many old gardens were sacrificed needlessly to the rage for improvement; and many monuments of the talent, taste, and industry of our forefathers may have thus been lost to us, which might otherwise have stood for years as landmarks in the history of the art.

Sir Walter Scott, who, in gardening matters at least, was conservative, and who had a poet's love and enthusiasm for the rugged beauty and grandeur of antiquity, speaks in bitter terms of the wholesale destruction of fine old gardens,

and referring more particularly to the then existing rage for changing every garden into a natural one, says:—"Nothing is more completely the child of art than a garden; who then would clothe such a child in the gipsy garb, however picturesque it may be?"

All styles in unsuitable places, or carried to extremes, have faults, and too enthusiastic innovators sometimes do great harm; yet looking around on our magnificent and picturesque domains, we must confess the obligations we owe to landscape gardeners; among whom, in our own day, we reckon as not least the late Sir Joseph Paxton, who has laid it down as a rule, "that the garden surrounding the house, whether an architectural terrace or bedded lawn, must, of necessity, possess uniformity; that the shrubbery immediately adjoining must partake of the same character somewhat modified; while the more distant portions and the park are willingly abandoned to the landscape gardener."

Not only in the grounds of the rich do we see improved taste displayed in gardening; true progress has even begun to be made in the ornamentation of the few square yards of ground allotted to suburban villas and cottages. Where our eyes were offended by the sight of a miniature geometric garden, bordered by scanty box and divided by paths half a foot wide, we now see a more elegant, because a simpler and more appropriate, taste displayed.

Without, therefore, being as sanguine as a writer in *Once a Week*, who some years ago looked forward to the time when every householder in London should have a flourishing garden on the roof of his house, we may still anticipate continued progression in the art of gardening; and hope soon to see as true a taste for, and appreciation of, the beauties of nature evinced in the humble plot of the cottager, as may now be seen in the more extensive grounds of the wealthy.

SOWING THE DESERT.

ONE interesting fact mentioned in Major Ross's paper, on his "Visit to Kej," read before the Royal Geographical Society, carries the thoughts back in welcome manner, to the incidents of past ages. In describing the Valley of Kej, the traveller notes the distribution of the date palm, which occurs in a scattered manner, but generally in lines, over the country. The inhabitants have a tradition which explains their growth by the circumstance of the soldiers of Alexander the Great's army having cast away the seeds of the dates they ate from day to day, during their memorable march. What a link between the present and the past! The date palm, most graceful and welcome of nature's boons to the inhabitants of arid regions—does not every artist who has dipped his pencil in the rich golden sunshine of Orient lands attest the fact in his work?—the palm, recognition of which from a distance is at once indicative of the oasis and the living spring, a link of connection between the age of "Macedonia's madman," and the nineteenth century! There is sentiment—nay, even poetry, in the thought; and we will cherish the legend, even though what logicians call proof, be wanting. And why should it not be so? A late Australian traveller—Mr. Allan Cunningham (not, of course, the poet and sculptor of that name, but the explorer, in the early part of this century, of the Darling and Brisbane rivers, and of the numerous affluents belonging to the extensive basin of the former) was in the practice of carrying with him a bag of peach stones, on his journeys into the wilderness of the interior, and of burying a few in the ground wherever he found a suitable spot, under the hope that their produce might at some future period afford welcome relief to the wayfarer. The soldiers of Alexander's army threw away their date stones, and they took root spontaneously; the modern explorer of the Australian "bush" deposited his peach stones in a spot where he had previously scratched away an inch or two of soil.

How to Destroy Moss and other Weeds on Walks.—What is the best and cheapest remedy to prevent the growth of weeds and moss in gravel paths? Those in the kitchen garden are edged with tiles, those in other parts are edged with turf. I have used refuse salt, but that destroys the turf.—T. N.—[We can recommend you nothing better than salt—care being taken to prevent its spreading so as to injure the turf. A good plan to prevent its being washed to the sides of the walk is to place a small ridge of sand along either side, about six inches from the edging, for a few days, until the danger is past. The salt may be applied in a dry state, or with boiling water, which is the quickest. Whatever you apply to kill the weeds is liable to be washed by rain to the sides, and so may destroy the turf. Hand-picking is, therefore safest.]

HARDY PLANTS IN FLOWER ROUND LONDON.

(FROM MAY 16TH TO 22ND, INCLUSIVE.)

BY OUR OWN REPORTERS.

Abelia triflora	Convolvulus cneorum	Kalmia angustifolia	Saxifraga pyramidalis
Achillea Clavennae	Corydalis aurea	Lathyrus pisiformis	Rhei

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL REPORTER.

PRIVATE GARDENS.

Indoor Plant Department.—Allamandas, Statices, and other specimen plants brought into flower in stoves are now transferred to conservatories, where they occupy the warmest places. The coolest parts of these structures are furnished with New Zealand plants, Heaths, &c. Pelargoniums and Calceolarias, as they advance in growth, are neatly staked, and a little weak manure water is given to them occasionally, as well as to most other quick-growing soft-wooded plants. Climbers on pillars, as well as those trained on rafters, are judiciously thinned and tied, permitting the shoots to hang in graceful festoons. Passion-flowers, such as *hybrida floribunda*, *principes*, and *regalis*; *Hardenbergia monophylla*, *Kennedyia rubricauda*, *Tropaeolum*, and *Fuchsias*, contribute to the decoration of cool houses; and in stoves, *Stephanotis*, *Hoya carnosa*, *Clerodendron Balfourii* and *splendens*; *Allamandas*, *Ipomoea Horsfalliae*, *Bougainvillas*, *Jasminums*, *Cissus*, *Bignoniias*, &c. *Camellias*, *Oranges*, and *Azaleas* are frequently syringed, kept well shaded, and rather close; sometimes a little clear manure water is given to them. These are also pruned into shape, even those that have already been cut back are now being gone over a second time in order to induce stocky growth. Bulbous plants are placed on shelves, and are being gradually dried off. Orchids enjoy a uniformly moist temperature, and those

in flower are removed to the coolest end of the house or to an intermediate house, where they receive additional shade, and by being also kept cooler their blooming season is considerably prolonged. Suspended baskets and blocks on which plants are growing are occasionally taken down and steeped in chilled water to ensure thorough saturation. Fire-heat is greatly economised by shutting up early, and air is given with caution. Ferns receive plenty of moisture and shade, and where it is desirable to promote the growth of specimen plants of Blechnums, Lomarias, Dicksonias, &c., they are being shifted a second time.

Pits and Frames.—These are now nearly emptied of bedding plants, which are placed in sheltered positions out of doors. Where large specimen Fuchsias are required they are again shifted into rich rather rough material. Petunias are shifted as they advance, pinched so as to induce stubby plants, and their flowers are also picked off until the plants attain a good size; their growth is encouraged by weak applications of manure water. Some, however, prefer growing them without stimulants until after they have set their bloom. Carnations are top-dressed and staked, and the most forward removed to the conservatory. Where the production of really good blooms is aimed at, only a few are retained on each plant. Annuals sown in pots for conservatory decoration are kept near the glass, and have plenty of air. Chrysanthemums are shifted as they require it, some removing all shoots coming directly from the root except one, that is in cases in which the plants are required for exhibition. They are kept in cold frames, well aired, trained, and staked, they are also placed on beds of ashes in open sheltered places, frequently syringed and well attended to in the way of water. The finer kinds of Polyanthus are being divided and potted into a compost of good loam, enriched with leaf-mould or well decayed cow manure; they are then put in frames, well shaded for a time, and as soon as they get properly established, will be placed outside in sheltered positions, from both cold winds and sun. Antirrhinums for indoor blooming are shifted as required; those thought unworthy of being kept are planted outside. Young plants of Phloxes are potted singly as soon as properly rooted. Auriculas are kept in frames, from which the lights are removed when practicable; they are protected from heavy rains. Heartsease in pots are kept in frames facing the north; they are increased by means of cuttings.

Flower Garden and Shrubbery.—Most kinds of ornamental trees and shrubs are now beautifully in bloom. Hedges of Privet, Elder, or Hornbeam, rapidly making growth, are gone over and pruned with the knife. Borders in front of shrubberies are neatly trimmed, and in addition to the herbaceous and dwarf-growing plants which they contain, all empty spaces are being made up with Gladioli, turned out of pots, dwarf Dahlias, and any plants that can be spared from the stock of bedding material. Ranunculus and Irises, especially in damp ground, constitute a conspicuous feature in these borders. The unfavourable weather of the past few weeks has rendered it advisable to delay, for a time, the planting out of tender plants; which, when turned out, have made no progress, except in well-sheltered places. This week, however, has been more encouraging; and furnishing beds with summer plants has more earnestly engaged attention, the harder plants only being used first. Edgings are made to beds of one or two lines of Sempervivums or Echeverias, Cerastiums turned out of pots, Cineraria maritima, Centaureas, Saponarias, Violas, &c. The harder Pelargoniums are also being planted out, but such things as Heliotropes and Perillas are withheld for a time. Unless in warm and sheltered situations Dahlias have not yet been consigned to the open ground. In sub-tropical gardens but little has yet been done further than having the edgings made up, the beds prepared and held in readiness to be filled when convenient. Hardy edgings, such as Euonymuses, Santolina, Ivy, &c., are being pruned. Aralia Sieboldii has stood the winter out of doors near London unscathed, and is now putting forth young shoots. Green-leaved Yuccas in pots are being plunged in the lawns where they are required to form isolated specimens. Hollyhocks pushing many shoots have all removed to three or so, according to the strength of the crowns; and, where not in prominent positions, a mulching of rotten manure is placed around their roots. Phloxes and Pentstemons are top dressed with well-decayed manure, slightly forked in. Hardy annuals sown last month are being transplanted; those from September sowings are in full bloom. Sowings of Mignonette, Saponaria, Nemophila, Collomias, &c., for late flowering, are still being made in shady borders, from which they may be transplanted. Lophospermums, Cobosas, Tropaeolums, Sweet Peas, Scarlet Runners, and other climbing subjects are planted where they can receive a little support. Roses are being mulched, and syringed occasionally; sometimes with tobacco-water. Choice Rhododendrons, and other shrubs, are also being mulched, either with decayed leaves or litter.

Indoor Fruit Department.—Pines, the fruit of which is colouring, are kept drier at the root, and also as regards the atmosphere, than others; those swelling fruits are assisted by moderate applications of manure water, a bottom heat of 85°, and an atmospheric one of from 70° to 80°. Succession plants are encouraged, and the most forward of them shifted; these will be required for autumn fruiting. Suckers, as they can be procured, are twisted off and potted. Vines approaching maturity are kept at a steady temperature, and a decrease of atmospheric moisture is allowed with a more liberal supply of air. In order to promote well-coloured fruit, as well as firm, thoroughly ripened wood, the supply of front air is limited; but a little top air is left on day and night, according to circumstances, and the temperature maintained by fire heat. Grapes generally are being thinned and the shoots pinched and tied; later houses are allowed a little fire heat to assist the setting of the fruit. Peaches and Nectarines beginning to ripen, have a drier atmosphere and more air than hitherto. In order to prevent the ravages of red spider, now that syringing has been discontinued, the hot-water pipes are smeared with sulphur. Advancing crops are liberally syringed and the young wood thinned, only leaving that necessary for next year's crop. Cherries bearing fruit, are allowed plenty of air, and as the fruit begins to colour, they are sparingly watered. Such trees as have borne fruit are removed to temporary protections for a time, where they are freely supplied with water at the root and overhead; they are afterwards plunged in the open ground. Figs are frequently stopped, and if shoots are not produced vigorously, weak applications of manure water are given. Melons ripening, receive little water, as it would spoil their flavour; those in beds are placed on tiles, slates, or pieces of wood; and such as are on trellises are supported by pieces of net, or by a piece of board placed under each fruit and attached to the wires. Thinning the wood, removing male flowers, fertilizing female ones, and giving water both at the root and overhead are operations necessary in the case of advancing crops. Cucumbers also receive plenty of water, and as their roots make their appearance above the surface of the bed, they are top-dressed with manure; and to those in a bearing state manure water is given. A few of the strongest Tomatoes, and best hardened off, are being planted along the foot of south walls. Of Strawberries, another succession is introduced to the forcing house.

Hardy Fruit and Kitchen Garden Department.—Fruit trees on walls are being carefully disbudded. Over-luxuriant shoots are stopped, in order that the sap may be more equally distributed. Frequent syringings from the garden engine are given, and where Aphides are present tobacco-water is used. The operation of training and nailing the young shoots is being attended to. Apricot and Peaches are being thinned, diseased leaves picked off, and all suckers removed. In the kitchen garden Brussels Sprouts, Savoys, and Cauliflowers are being transplanted into deeply-worked, well-manured soil. Another plantation of white Paris Cos Lettuce is being made. The ground intended for the main crop of winter Greens and Broccoli is being prepared by well manuring and deeply digging it. These crops generally succeed Celery, autumn-sown Onions, Parsnips, or early Cabbages, as may be most convenient. New Zealand Spinach is being planted out, as is also Basil in rich warm soil. A sowing of Scarlet Runners for a succession is now made, also of French Beans, and a few of the Broad Windsor. Some dwarf Marrow Peas are now sown, and early ones topped; Spinach for succession is being sown, also a few seeds of Scorzonera and Salsify. A few Lettuces and Turnips, if required, are sown in cool shady places; sowings of Rampion and Cress Salad are also being made. Root-crops, such as Beet, Carrots, Parsnips, and Turnips are thinned as they advance in growth. Potatoes are being hoed, and in some cases the soil between the rows is loosened with a steel fork; a little earth is drawn to the most forward of them. Ridges for Cucumbers are being prepared, and the ground is also being got ready for celery.

NURSERIES.

SOFT-WOODED plants are being increased for next season's sales. Many of the finer kinds of tricolor Pelargoniums are being retained, and placed in heat to yield cuttings more abundantly. Cinerarias from rooted slips are being potted singly and kept in cold frames, those from seed are being pricked off, and the furthest advanced potted into sixty-sized pots. Hard-wooded greenhouse plants, such as Epacries, Boronias, &c., are now being propagated from cuttings of the young wood, inserted in pots filled to within half an inch of the brim with light peaty soil, a surface being added of pure sand. Cuttings of such plants are taken off an inch or so in length, stripped of a few of their lower leaves with a pair of shears, and inserted in the pots, on which bell-glasses are placed; the pots are then plunged in gentle heat, and kept well shaded. Rooted cuttings of these are potted singly into thumb pots, using a compost of peat and sand.

Ceropagias, Allamandas, and Bignonias are also similarly propagated, only larger cuttings are used. Indigofera decora, in addition to being grafted, is also increased by means of cuttings of the young wood, about six inches in length. Stephanotis is increased from cuttings, having two joints, one of which, divested of the leaves, is placed in the soil, whilst the other, on which all leaves are left, remains above the surface. The cutting pots are plunged, in gentle heat, under hand-lights. Rooted cuttings of Roella ciliata are being potted off singly into small pots. Mandevillas and Maurandias from seed are being potted singly, and placed on the shelves of an intermediate house well shaded. Anthurium Scherzerianum from seed is pricked off into a mixture of chopped sphagnum, peat, and silver sand, kept rather close and well shaded. Allocasia Jenningsii is increased by means of the eyes that are produced on its roots. Fern spores are still sown, covering the surface of the pots with pieces of glass, and placing them in a shady part of a pit; those requiring potting are attended to. Crowns of Isoteleia gracilis are being divided into small pieces, potted singly, and placed in gentle heat. Delphinium nudicaule is sown in pans of sandy loam, in very gentle heat. Seedling Rhododendrons are now being pricked off into pans of sandy peat, and kept well shaded; rooted cuttings are potted singly. Seedlings of R. ponticum for grafting purposes are re-potted into six-inch pots, and placed on the north side of walls or hedges; these will be operated on next spring. Thujae are being grafted in close frames inside the propagating house, and well shaded. Azaleas, Oranges, Acacias, and other plants of that kind making growth, are being gone over a second time, and the young wood pinched in, so as to encourage another growth, and make stumpy plants. If rightly treated, they will mature such wood before the end of the season. Young Vines are potted into eight-inch pots, and arranged, some along front stages, and others on centre stages, of houses in which there is a little heat.

Outdoor Department.—Suckers on grafted and budded fruit or other trees, are removed as soon as they appear. The same care is also exercised in the case of Roses. The branches of Wistaria sinensis are being layered by sharply bending the branches into the earth, where they are fixed by means of wooden pegs; the shoots are also sometimes cut half through to facilitate the rooting process. Shrubs, such as Berberis, Cotoneaster, Spiraea, Ghent Azalea, &c., are being pruned, an operation which prevents them from getting unshapely. Shoots infesting the base of young fruit trees and bushes are removed, none being left below the required head; on seedlings that have set fruit, all are picked off, except two or three on each, which are merely left for determining their value. Robinias, and a few such out-door plants that have been grafted on the tops of tall stocks, which have been bent down so that the grafts might be covered with mould, have, in some cases, made good progress; and where sure signs of union is manifest, they are allowed to get up. Evergreen bushes are pruned into shape, and standards firmly staked. Young Arbutus are transplanted into lines twelve inches apart, by six inches plant from plant. Seedling Deodars are also set in rows twelve inches by three inches. Herbaceous and alpine plants in pots are placed outside on beds of ashes; those requiring it are top-dressed. Phloxes in pots are planted out into beds.

MARKET GARDENS.

FRUIT TREES, especially Pears, also bush fruit, present encouraging signs of a fair crop. Ground crops, notwithstanding the backward weather we have lately experienced, are looking well, though less forward than in more favourable seasons. Early Cauliflowers are being obtained from plants reared under hand-lights, in clumps of three or four together; the next in succession are those planted out in lines, which, although few of them are as yet headed, promise an excellent crop; other plantings are coming on in time to succeed these. Cos Lettuces, grown between the lines of early planted Cauliflowers, are fit for market; and in succession to these are those planted between the second crop of the same; these are now being tied round with strings of matting, to cause them to blanch. The crop of early Cabbages is nearly consumed. Leeks and Carrots from last year's sowing, also young Carrots raised in frames, are plentiful. Abundance of Parsley and herbs are obtained from spaces under fruit trees. Neither Peas nor Beans are much grown in market gardens, with the exception of early ones; these are now in flower, and pods are beginning to be formed. Spinach is plentifully obtained from early broadcast sowings, made on pieces of ground planted with Cabbages or Cauliflowers; now that the Spinach is being cut for market, the other crop has more room for development. Asparagus has not been so good this season as usual, owing doubtless to the cold, ungenial weather; now that a favourable change however has set in, better produce is anticipated. Turnips from March sowings are of fair size and good quality. Many of the Mushroom beds are exhausted, but a few of them yet continue to produce fair crops. Cucumbers

in frames are obtained in abundance. Pine-apples in astonishing numbers are produced in some of these establishments, and the quantities of Grapes and Strawberries they are now sending to market are wonderful.

Cucumbers in frames are regularly pinched and thinned; fruits inclined to be crooked are placed in tubular glasses, about 2½ inches in diameter, by a foot in length. Vegetable Marrows under hand-lights are slowly advancing; those under baskets, and having the assistance of a little bottom heat, have also done pretty well, but where they have had no bottom heat, and only baskets for a protection, they have succumbed to the cold weather; such blanks are now, however, made good from the reserve stock. Tomatoes have been mostly grown, two in a six-inch pot; the furthest advanced and best hardened off are planted out about three feet apart, leaving the two together at the base on both sides of spent Mushroom ridges, and also at the foot of fences and walls. Lettuces are being tied with pieces of matting, and young plantations are made from those sown between beds of early Carrots. French Beans sown on the tops of Asparagus ridges have suffered considerably from cold, those in sheltered places are doing well; and the earliest ones sown in frames are having their protection removed. Another main sowing is being made in lines with a row of Lettuces between them. Young Onions from early spring sowings in frames, have the frames removed, and the crop is now in a fine condition to succeed the autumn-sown ones for salading. Radishes are being sown in six feet wide beds. Young Celery plants are transplanted in the open ground in beds, in rows six inches apart, and two or three inches plant from plant, with eighteen-inch alleys between the beds; in some cases they are only in lines, not in beds, but here the lines are eight or nine inches apart; a line of them is also planted between rows of Cabbages. Young Cabbages for Coleworts are being planted between lines of Moss Roses under fruit trees; Stocks, for producing cut flowers, are also planted in a similar situation. Cabbages are also planted in spaces emptied by the removal of early ones for market. Bush fruits that have been layered have some earth laid over their shoots. Loosening the soil among growing crops is assiduously persevered in.

MY WINDOW IVY.

Over my window the Ivy climbs,
Its roots are in homely jars;
But all the day it looks at the sun,
And at night looks out at the stars.

The dust of the room may dim its green,
But I call to the breezy air;
“Come in, come in, good friend of mine!
And make my window fair.”

So the Ivy thrives from day to day,
Its leaves all turned to the light;
And it gladdens my soul with its tender green,
And teaches me, day and night.

—Hearth and Home.

The Gardener and the Owls.—Our highly esteemed correspondent Mr. J. Barnes is, as is well known, an enthusiastic student of natural history. The following is one of his adventures when on this usually peaceful pursuit, when head gardener at Bicton:—“One barn owl's nest that I knew was in the hollow of an immensely large ivy-clad elm tree that stood on the lawn at no great distance from the mansion. I never can, and I believe I never shall, forget, how terribly I was once taken aback, on a visit to this nest, one evening in the month of September. I was crossing the lawn, when there arose a heavy thunderstorm. I ran under the leeward side of this tree for shelter. Hearing, while standing there, the young owls hissing and snapping their beaks, at once suggested to me to run up and have a look at them. The entrance to their den was about eighteen or twenty feet from the ground, and the tree, as stated, was clothed with large strong ivy. Up I climbed, and no sooner had I arrived, and was about having a peep, when, in an instant, I was furiously and desperately attacked by both owls. Oh, what a battering with their wings—pecks with their beaks—scratches and pinches with their claws—I did receive from those two desperate beauties! I was in no small danger of losing my eyes, or of getting battered down from the tree. I slunk down the best way I could, keeping my face as well sheltered and as near the tree as possible; unfortunately my cap was torn or battered off, and fell to the ground in the early part of the battle, and my poor head received a terrible combing, battering, scratching, and pecking. When I arrived on the ground, I was still the object of an unmerciful attack. I ran with all speed to a large Portugal laurel tree, hard by. Mine enemies were still whirling round, and watching me. I took out my knife and cut off a branch, trimming off the side branches and leaving the leaves on the summit. I then sallied forth, with pretty good assurance, in defence, followed by mine enemies at a considerable distance. The branch I kept whirling about, and kept them at bay, till they were tired of my company. I assure you I was very glad to get quit of such society.”

COVENT GARDEN MARKET.—May 24th.

Flowers.—Those in pots chiefly consist of Calceolarias with well formed flowers beautifully marked. Pelargoniums of all kinds, some of the show varieties bearing very large trusses of bloom. There are also good examples of the Golden-rayed Lily; sweetly scented, double-flowered Gardenias; well bloomed, gracefully grown plants of single and double Fuchsias; Petunias, both single and double, and of various colours; fine collections of Heaths, a few small plants of Azaleas, Roses, Rhododendrons, Hydrangeas with immense flower heads, and many other noteworthy plants. In addition to those in flower, we noticed several fine foliaged plants, such as Cibadams, Begonias, Dracanas, small Palms, and a great variety of Club Mosses and Ferns; the last included the more graceful forms of Adiantum and Pteris, some of the more easily grown Polypodiums, a few Aspleniums, and white and yellow-powdered Gymnogrammas. In addition to these, hardy shrubs in pots are supplied in great abundance, and consist of Aucubas, Euonymuses, the finer kinds of Maples, Box, dwarf Cypresses, and other small Conifers. Cut blooms and hardy flowering plants are also liberally supplied.

SOCIETIES, EXHIBITIONS, &c.

ROYAL BOTANIC GARDENS, REGENT'S PARK.
(MAY 22ND AND 23RD.)

THE weather during the two days on which this show was held was remarkably fine, and the display of plants, although perhaps inferior in point of numbers to that of preceding years, was nevertheless all that could be desired. Azaleas were abundant and brilliant; of these, six specimens, including two white ones, Vesta and Gledstanesi, and four red-coloured ones, named, coronata, conqueror, genia, and Extravagia, were remarkable for large size. These formed pyramids, some six feet through and nearly nine feet in height, and so deeply were they bloomed that the foliage was hardly distinguishable. In addition to obtaining the first prize in their class they were awarded a gold medal for superior cultivation. On smaller plants were some very fine flowers, but to these we have alluded on former occasions.

Roses in pots, both from nurserymen and amateurs, though really meritocratic, were nevertheless scarcely so fine as were shown last week at South Kensington. Several boxes of cut blooms beautiful in colour and form were also contributed.

Cape Heaths, in the form of specimen plants, were well represented, and some staged in miscellaneous collections were beautifully grown and flowered. Amongst them were plants of Erica coccinea, minor over three feet through, compact and well flowered; E. candissima, four feet in diameter; tricolor elegans, massive plants, fully four feet through, and the same in height; Massoni, about two and a half feet through, the points of the shoots bearing from twelve to eighteen whorls of showy flowers. Amongst smaller plants we also noticed nice examples of E. Springeri and Devoniana, both fine dark-flowered kinds, depressa multiflora, elegans delecta, and others.

Specimen stove and greenhouse plants were in beautiful condition, large and finely flowered. Conspicuous amongst them were Clerodendron Balfouri, well furnished both with leaves and flowers; Dracophyllum gracile fully four feet through; Tremandra ericifolia, a plant about four and a half feet in diameter, and densely furnished with masses of graceful shoots bearing abundance of bloom; Pimelea Hendersoni, a complete mass of soft, rose-coloured flowers; and some fine plants of Aphelexis, Genetyllis, and Dipladienias, the last scarcely in perfection.

Two fine collections of Herbaceous Calceolarias were furnished, one being superior to the other in having flowers of finer form, whilst the other excelled in possessing pure and distinct colours; both groups were, however, examples of great perfection.

Show Pelargoniums were also represented, but in the amateurs' class only, and these, except one collection, were not so fine as we have often seen them. Among first-prize kinds the following were particularly worthy of mention, viz., Maid of Honour, Fair Rosamond, and Patroneess.

Orchids were tolerably good. Besides those staged in classes specially set apart for them, several fine kinds were noticeable amongst miscellaneous collections of plants. Amongst Dendrobiums, Devonianum, formosum, and nobile were the best; there were also some good plants of Cyprideum villosum, Lowii, caudatum, and fine broad petalled varieties of barbatum: Of Aerides there were some good plants, such as Fieldingii, Warneri, with beautiful light, rosy, purple flowers, and a few specimens of odoratum; Angulo macrantha, with beautiful canary-coloured flowers, contrasted admirably with the rich tints of some of the others. The most beautiful Orchid in the show perhaps was Saccolabium retusum, with two spikes of bloom in splendid condition; there were also several fine Oncidioms, Odontoglossums, Laelias, and others; likewise a prettily bloomed little plant of Chysis Limminghi.

Of Ferns there was a good supply, both of tree, ordinary, and filmy kinds. Conspicuous amongst these was a grand specimen of Adiantum Farleyense, fully four feet through, and densely furnished with fine healthy dark-green foliage. There were, moreover, several smaller plants of the same, and some fine examples of A. concinnum latum, intermedium, tenerum, &c. In addition to these we noticed a fine example of Asplenium Nidus, with fronds nearly five feet in length and ten inches in width; these more resembled young Banana leaves than those of Ferns. There were likewise a grand plant of Lomaria Gibba, with fronds about three feet in length and eighteen inches in breadth; a fine specimen of Gleichenia semi-vestita; some pretty little plants of Cheilanthes elegans, Pteris scaberula, &c.

Prizes were offered to nurserymen for a group of flower-garden plants in pots or boxes arranged for effect; in this class Messrs. E. G. Henderson, St. John's Wood, were the only competitors. They staged a charming group, edged with Echeveria secunda glauca; next to them was a border of golden Feverfew, then a border of Coleus Verschaffeltii; at the back of these were arranged, in boxes ten inches by ten inches, several kinds of alpine plants, either remarkable for their flowers or for the beauty of their foliage; these were relieved by other boxes containing flowering plants, such as Petunias, dwarf Pelargoniums, Mimuluses, &c. The background of this group was made up of some of the fine kinds of variegated Yuccas, Dracenas, Palms, Aralias, and a few good plants of Streptocarpus juncea. In this collection we also observed two very fine varieties of Cineraria maritima, with deeply incised white leaves.

Among the first-prize lot of hardy herbaceous plants were grand specimens in twelve-inch pots of Cheiranthus Dilleni, Linum flavum (fine), two good varieties of Iris germanica, named spectabilis and Walner, the first a deep purple and the latter a light purple kind; Iberis correaefolia (a fine plant for exhibition purposes), three Pyrethrums, a double Paonia, Veronica verbenacea, Spiraea japonica, and Ranunculus acris plena. From Mr. Ware came a very good plant of Astilbe (Spiraea) japonica, and two good Trollius, named europaeus and Fortunei, shown in large pots, while the remainder of his collection consisted mostly of flat pans apparently made up of duplicate plants from store pots.

Certificates of merit were awarded to the following:—Golden Eagle and Enchantress, two pale pink Pelargoniums from Messrs. E. G. Henderson; to forcing Pink cocinea, and tree Carnations Marchioness of Westminister, Princess Christian, Queen of Belgians, and Caliban, from Mr. Turner; to pyramidal stock, Maive Beauty, from Mr. R. Dean; to Zamia cycadoides, Veitchia Canterburyana, Kentia australis, and Davallia Ternmannii, from Mr. B. S. Williams; to Iberis Pruittii, from Mr. R. Parker; and to Polystichum angulare gracile Grayii, var. cristata, from Messrs. Lucombe, Pince, & Co., of Exeter.

The following prizes were awarded, viz.:—

Nine stoves and greenhouse plants: 1, Mr. J. Ward, Leyton; 2, Mr. J. Wheeler, Stamford Hill; 3, Mr. G. Wheeler, Cheshunt; Six stove and greenhouse plants: 1, Mr. J. Ward; 2, Mr. J. Wheeler; 3, Mr. G. Wheeler, Regent's Park; Six stove and greenhouse plants (nurserymen): 1, Messrs. J. Jackson & Son, Kingston; 2, Mr. Morse, Epsom; 3, Mr. W. Cubthush, Barnet, Herts. Twenty greenhouse plants in eight-inch pots (nurserymen): 1, Messrs. J. Jackson & Son; Nine exotic Orchids: 1, Mr. J. Ward; 2, Mr. Isaac Hill, the Poles, Ware, Herts; 3, Mr. T. G. Wheeler; Six exotic Orchids (amateurs): 1, Mr. T. Godfrey; 2, Mr. J. Ward; 3, Mr. W. Cubthush, Barnet, Herts. Twelve Cape Heaths in twelve-inch pots (amateurs): 1, Mr. J. Ward; 2, Mr. W. Cubthush, Barnet, Herts. Two Cape Heaths in twelve-inch pots (nurserymen): 1, Messrs. J. Jackson & Son. Six Ferns: 1, Mr. G. Wheeler; 2, Mr. B. S. Williams; Six Palms: 1, Mr. B. S. Williams; 2, Mr. T. G. Wheeler; Six exotic Ferns (amateurs): 1, Mr. T. Godfrey; 2, Mr. R. Ritchie, Hampstead; 3, Mr. G. Wheeler. Six exotic Ferns (nurserymen): 1, Mr. B. S. Williams; Six Roses in pots: 1, Mr. Terry, Lyndhurst, Wilts; Nine Roses: 1, Mr. G. Morris, Pinner; 2, Mr. C. Turner, Slough. Twenty roses in pots: 1, Mr. T. G. Wheeler; Six greenhouse Azaleas (amateurs): 1, Mr. G. Neighbour, Great Marlow; 2, Mr. C. Turner; 3, Mr. G. Wheeler. Six greenhouse Azaleas (nurserymen): 1, Mr. C. Turner; 2, Messrs. Lane & Son; 3, Messrs. Jackson & Son. Three greenhouse Azaleas (nurserymen): 1, Mr. C. Turner; 2, Messrs. Lucombe, Pince, & Co.; 3, Mr. J. Wheeler. Two twelve-inch pots (nurserymen): 1, Mr. C. Turner; 2, Messrs. Lane & Son; 3, Messrs. Jackson & Son. Three greenhouse Azaleas (nurserymen): 1, Mr. C. Turner; 2, Messrs. Lucombe, Pince, & Co.; 3, Mr. J. Wheeler. Two twelve-inch pots (nurserymen): 1, Messrs. Lane & Son; 2, Messrs. Lucombe, Pince, & Co. Group of stove and greenhouse plants arranged for effect: 1, Mr. G. Morse. Group of bedding plants arranged for effect: 1, Messrs. E. G. Henderson & Sons. Group of Ferns, Ferns, &c., arranged for effect: 1, Mr. B. S. Williams; 2, Messrs. Lucombe, Pince, & Co.; 3, Messrs. Jackson & Son. Twelve hardy herbaceous plants: 1, Mr. R. Parker, Tooting; 2, Mr. T. S. Ware, Tottenham. Nine show Pelargoniums (amateurs): 1, Mr. Ward; 2, Mr. James; 3, Mr. Neighbour.

The following miscellaneous prizes were awarded:—

To a collection of plants, from Mr. B. S. Williams, a silver medal; to eight boxes of cut Roses, from Messrs. Paul & Son, Cheshunt, a silver medal; to a collection of cut blooms of Pyrethrums and Pansies, and a group of hardy

foliage plants from Mr. Ware, a silver medal; to a collection of Carnations, from Mr. Turner, a bronze medal; to a collection of Calceolarias, from Messrs. Dore & Son, a silver medal; to another group of the same, from Mr. James, a bronze medal; to a collection of hardy Ferns, from Mr. Smea, Finsbury Circus, a bronze medal; and to a collection of plants, from Mr. Wheeler, a silver medal. A certificate was awarded to a collection of cut blooms of Pansies, from Mr. James.

NATIONAL HORTICULTURAL EXHIBITION AT MANCHESTER.

ANOTHER noble show, and one in some respects a decided improvement on preceding ones, remarkable for merit as they have been. The more noteworthy features were the noble stove and greenhouse plants shown by Mr. Baines, of Southgate; the excellently grown roses of Mr. George Paul, of Cheshunt, and the many fine Orchids shown by various exhibitors. The herbaceous plants too were a feature of more than ordinary interest. Messrs. Rollinson, of Tooting, showing and winning with one hundred plants. The select Orchids and other hothouse and greenhouse plants were ranged in the exhibition house, and the Roses, Pelargoniums, and other hardier specimens in the tent *annexe*, which, set at right angles with the conservatory, is now regarded as an established feature of the show. The whole arrangement is much improved, and reflects great credit on Mr. Bruce Findlay, to whom these exhibitions owe so much.

The following prizes were awarded, many of them being on a very liberal scale, viz.—

Stove and greenhouse plants : 1, Mr. H. L. Micholls ; 2, Mrs. E. Cole & Sons ; 3, Mr. J. Stevenson. Twelve Roses in pots : 1, Messrs. Paul & Sons; 2, Lane & Miscellaneous plants : 1, Mr. Micholls ; 2, Mr. T. Shuttleworth ; 3, Mr. Dixon. Alpine plants : 1, Mr. C. L. Moore ; 2, Messrs. Rollinson ; 3, Mr. Ware ; 3, Messrs. Yates. Ten Roses in pots : 1, Mr. Wilkinson ; 2, Mr. Fildes. Orchids : 1, Mrs. Calleender ; 2, Dr. Ainsworth ; 3, Mr. Stevenson. Six Orchids : 1, Mr. Fernley ; 2, Mr. Broome ; 3, Mrs. Calleender. Specimen Orchid : 1, Mr. Fernley ; 2, Mr. Gottschalk ; 3, Dr. Ainsworth. Sixteen Orchids : 1, Mr. S. W. Williams ; 2, Messrs. J. Brooke. Six orchids : 1, Mr. Williams ; 2, Mr. Yates ; 3, Messrs. Lane & Greenhouse Azaleas : 1, Mrs. Cole ; 2, Messrs. Lane. Ten Azaleas : 1, Mr. May. Two sets of the same species equally. Six stove and greenhouse plants : 1, Mrs. Shuttleworth ; 2, Mr. Bennett. Eight stove and greenhouse plants : 1, Mrs. Cole ; 2, Messrs. Yates. Ten miscellaneous plants : 1, Mr. Williams ; 2, Mrs. Cole ; 3, Mr. Dixon. Thirty miscellaneous plants, arranged for effect : 1, Mr. Fernley ; 2, Mr. Longshaw ; 3, Mrs. Calleender. Ten stove and greenhouse plants : 1, Mr. Stevenson ; 2, Mrs. E. Cole & Son ; 3, Messrs. Yates. Eight Heaths : 1, Mrs. E. Cole & Son ; 2, Mr. Ainsworth ; 3, Mr. Stove. One set of the same species. One set of the same species. Mr. Stevenson. Mr. Shuttleworth. Hardy ferns : 1, Mr. Crowe ; 2, Mr. Martin ; 3, Mr. Shuttleworth. Tree ferns : 1, Messrs. Brooke ; 2, Mr. Shaw. Eighteen hardy Ferns : 1, Mr. Rylands ; 2, Mr. Dixon. 3, Messrs. Rollinson. Pelargoniums : 1, Mr. Bennett. Ten Pelargoniums : 1, Mr. Rylands. Eight Pelargoniums : 1, Mr. Rylands. Fuchsias : 1, Mr. Bennett. Twenty-five roses in pots : 1, Messrs. Paul ; 2, Messrs. Lane. Zonal Pelargoniums : 1, Mr. Bennett ; 2, unawarded ; 3, Mr. Stevenson. Variegated or tricolored Pelargoniums : 1, Mr. Yates ; 2, Mr. J. Bennett ; 3, Mrs. Howard. Gunnera. Osmunda. Palms, and other plants, arranged for effect : 1, Mr. Yates ; 2, Mr. Williams ; 3, Messrs. Rollinson. Thirty Rhododendrons : 1, Mr. Yates ; 2, Messrs. Lane. Hardy Conifers : 1, Mr. Shaw ; 2, Mr. Caldwell ; 3, Messrs. Yates. Hardy Evergreen trees and shrubs : 1, Mr. Shaw. Herbaceous Calceolarias : 1, Mr. Barnes ; 2, Mr. Rylands. 1, Mrs. McLaren. Cinerarias : 1, Mr. Waldwick ; 2, Mr. Rose. Succulents : 1, Mr. Rylands. 2, Mr. Barnes, Dasyphyllum : 1, Mr. Rylands. 2, Mr. Stevenson ; 3, Mr. Shaw. Dracaena or Corn Plant : 1, Mr. Rylands ; 2, Mr. Broome. One pair of Palms : 1, Mr. Stevenson ; 2, Mr. Broome ; 3, Mr. Bennett. New and rare plants : 1, Messrs. Williams ; 2, Mr. Dixon ; 3, Mr. Shaw. New and rare plants : 1, Messrs. Rollinson ; 2, Mr. Williams ; 3, Mr. Dixon. Iives : 1, Messrs. Lane ; 2, Mr. Dixon ; 3, Mr. Shaw. Six plants suitable for dinner-table decoration : 1, Mr. Yates ; 2, Mr. Dixon ; 3, Mr. Shuttleworth. Vase, Epergne, Centrepiece, for table : 1, Mr. Yates. Hand bouquet : 1, Mr. Turner ; 2, Mr. Calleender ; 3, Mr. Yates. 4, Mr. Rylands. For the most meritorious plant in the exhibition : 1, Mrs. Cole ; 2, Mr. Micholls. Cucumbers : 1, Mr. Heywood ; 2, Mr. Cameron ; 3, Mr. Hill.

MEETINGS OF SOCIETIES FOR THE ENSUING MONTH.

JUNE 3RD.—Coventry and Warwickshire Floral and Horticultural Society: exhibition of Flowers and Fruit; to be held in Coventry.

June 5th, 6th, and 7th.—Royal Horticultural Society, South Kensington: great Flower and Fruit show.

June 5th, 6th, and 7th.—Leeds Horticultural Society: ninth great show; to be held in the Royal Park.

June 12th, 13th, and 14th.—Floral Fete, York: Roses, and stove and greenhouse plants.

June 13th and 14th.—Lee and Blackheath Horticultural and Floricultural Society: summer exhibition of Flowers, Fruits, and Vegetables; to be held at "The Cedars," Lee.

June 19th.—Royal Horticultural Society, South Kensington: exhibition of Flowers.

June 19th and 20th.—Royal Botanic Society, Regent's Park: exhibition of stove, greenhouse, and hardy plants.

June 19th and 20th.—Brighton Horticultural Society: grand Rose, Fruit, and Pelargonium show.

June 23rd, 26th, 27th, 28th, and 29th.—Royal Horticultural Society: great show of Plants, Fruits, cut Flowers, and Vegetables; to be held at the Lower Grounds, Aston, Birmingham.

June 26th.—Bishop Stortford and Hertfordshire Horticultural Society; held at Halhingbury Place: Flowers and Fruit.

June 27th.—Newcastle-under-Lyne Horticultural Society: exhibition of Flowers, Fruits, and Vegetables; to be held in the Stud's Walk.

NORTH OF IRELAND HORTICULTURAL SOCIETY'S SHOW.

The spring exhibition in connection with this Society has taken place in the Royal Botanic Gardens, Belfast. The total number of entries was ninety-eight. The best class was the stove and greenhouse plants, of which there was a numerous assortment; and of those no particular set of plants could cope with the Azaleas. The first prize was a cup, presented by Messrs. Thyne, of Glasgow, and was awarded to Mr. William Bell, Lurgan. The second prize fell to Mr. Henry Hawkins, an amateur. The display of Rhododendrons was fine, the best being owned by Mr. J. B. Houston. There were numerous collections of different kinds of plants, prominent among which were some really fine specimens of Azaleas, Ferns, Coleus, &c. A quantity of magnificent Ethiopian Lilies attracted special attention; as did also a number of graceful Ferns, foliage plants, Heaths, and a collection of smaller plants. The finest of the single plants was a splendid Anthurium Scherzerianum, the property of Mr. Hawkins. A good specimen of Croton variegatum was also shown, beautifully shaped and well marked. The show was open for three days, but owing to the unpropitious state of the weather, the attendance was not so large as the merits of the show deserved. The amount awarded in prizes was nearly £200.

Leicester Square.—The riderless horse in Leicester Square that has so long stood without the shafts of ridicule, was sold the other day by auction for £16, the liberality of the bid being no doubt attributed to the fact that this neglected work of genius contained more than the ordinary proportion of lead. It will be remembered—for the facts are of recent date—that when the illustrious obscurity supposed to have been one of the Kings of Brentford sat astride this doleful charger, some daring wags made their way into the enclosure, then fenced with an iron railing, and painted the equestrian statue in a highly grotesque manner. Subsequently the monarch was tumbled out of his *seats*; the removal of the figure that had stuck there so long leaving a ghastly hole in the poor animal's back. Bit by bit the image of fallen greatness was broken up by young thieves, and carried off to the marine-store dealer whose reputation stood the highest for giving most money and asking fewest questions. Preparations have been made for the removal of that greater part of the ill-treated design which has been more legitimately disposed of; but up to a very recent date it remained on its pedestal. There is a talk of selling Leicester Square itself, and speculators are said to have their eyes on the bargain. The reserved price is said to be £30,000. In order to allow intending purchasers to examine minutely the freehold property before they bid for it, all the railings that formerly surrounded the square have been removed.

ANSWERS TO CORRESPONDENTS.

C. H. (Yes; rather remarkable. We may have something to say in reference to them hereafter).—**GREAT MALVERN** (*Apionopteron distachyon*).—F. M. (1. *Lithospermum purpureo caruleum*; 2. next week; 3. apparently *Mertensia virginica*; 4. *Astrantia major*); 5. *Veronica officinalis*; 6. *Thlaspi arvense*.—D.—(One of the many varieties of *Azalea japonica*).—Mrs. P. (Your Rhododendron is known in the Bagshot Nurseries as "Jackson's Seedling").

DIED, on the 17th inst., after a short illness, Mr. George Young, many years gardener to W. H. Stone, Esq., M.P., of Leigh Park, Havant, aged 56 years.

THE GARDEN can be had in neatly covered monthly parts.—On sale at Messrs. Smith & Son's bookstalls, and may be had through all booksellers. Part V., for April, now ready, price 1s. 5d. Publishing Office, 37, Southampton Street, Covent Garden, London, W.C.

The Name and Address of the writer are required with every communication, though not for publication, unless desired. Letters or inquiries from anonymous correspondents will not be inserted.

All questions on Horticultural matters sent to **THE GARDEN** will be answered by the best authorities in every department. Correspondents, in sending queries or communications of any kind, are requested to write on one side of the paper only.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

Readers who may find it difficult to procure **THE GARDEN** regularly through the newsagents, may have the numbers sent direct from the office, at 19s. 6d. per annum 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained through all newsagents at the railway book-stalls, and from the office.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE SIX OF SPADES.

CHAPTER XV.

Mr. Oldacre's Story.—The Lady Alice (continued).

The dear, said Mr. Oldacre, as he resumed his story, having scampered away from the carriage-road, alarmed at the unusual sound of Lord Evelyn's merry laugh, had turned, and were still gazing in astonishment at the phæton going up the park, when another equipage reached the entrance gates, containing two occupants, almost as upright, and quite as cold, as the pillars through which they passed. These were our noble marquis and a friend of his ("The Viscount," as he was afterwards called by us; Lord Evelyn's friend being known as "The Captain"), very much resembling himself, both in the pallor of his countenance and in the haughty reserve of his demeanour. There they sat, straight and gloomy as a brace of Irish yews, which could not raise a berry—that is, a smile, between them.

I was reading the other day, in one of the books* belonging to our "village library," for which we are mainly indebted to his reverence in the corner, how that the demeanour of King Philip II. of Spain, which was almost sepulchral, was ascribed partly to a natural haughtiness, and partly to habitual pains in the stomach, occasioned by an inordinate love of pastry. If the marquis and his friend were similarly affected, they must have recently paid a visit to the confectioner's, and stayed there until they had cleared the counter.

This solemnity of expression had probably been increased by the fact, which I afterwards heard from the postillions, that Lord Evelyn, with his pair, had passed the marquis, with his four, in jubilant derision and a hand gallop not long before. If the latter had been drawn by four-and-twenty, the former would have gone by him just the same, for he always would be first. He had a sincere affection for his brother, but he delighted, as I have heard him say, "in cutting down old 'Quis," and when he had pounded him in a run, or bowled him in a match, he was happy. He was master in all sports, save one. The stern, imperceptible marquis was a dead shot. If all the pheasants, partridges, and wild ducks upon the estates to which he was heir, had risen simultaneously, whirring and quacking around him, he would have selected his bird, and slain him as calmly as though there were but one. And he was never so solemnly fatal, as when, after Lord Evelyn had fired hurriedly and harmlessly his right and left, he deliberately "wiped" the fraternal "eye." I used to load for my lord sometimes in covert shooting, when all available hands were pressed into the service; and I remember him saying to me on one occasion, as he handed me the smoking gun, "There's only one living thing in the world, Oldacre, which I thoroughly abhor and detest, and that's a beastly woodcock."

You begin to think, I fear, that I am "running to leaf," and, therefore, although we gardeners have naturally a taste for garnish, I must prune accordingly. After a short visit, the marquis and Lord Evelyn went away with their friends; and rumours reached us from the servants' hall, that the latter had left a brace of hearts behind them, in custody of my Lady Alice. The duke, it was said, regarded with complete approbation the suit of the viscount, who was heir to an ancient and wealthy earldom; but the daughter preferred the guardsman.

That there was some special attraction at the castle for

* Motley's "History of the Dutch Republic," vol. I.

these young gentlemen was evident from the fact that they both revisited it a few months after their departure, together with a great number of other guests, who were invited to celebrate the coming of age of our marquis. And now comes a chief event in my story. A grand ball was to end the festivities, and all the resources of our immense establishment were to be taxed to the utmost, as they say at the circus, to make the entertainment a success. We gardeners were busily engaged, I can assure you, in collecting and preparing all our eligible plants from the houses, carrying them to the castle, and arranging them in the halls, ball-room, &c. The demand for cut flowers, upon the day of the ball, was (so my father, then the head gardener, pronounced it) murderous; flowers for the reception-rooms, flowers for the supper-table, flowers for the hair, flowers for the hand, and flowers for the gentlemen's coats.

As I was at that time head foreman in the plant department, the care of the great conservatory was entrusted to me during the night of the ball. I was to replace any of the low flowering plants, which formed an edging to the circular beds, and which might be disarranged by the trailing garments of the ladies; to supervise the fountains, which were at times eccentric in their behaviour; to keep an eye upon the coloured lamps, &c. When the guests came into the conservatory, I was to retire behind a stage for plants at the end of the building, where I should be effectively concealed within my leafy bower.

Here, without any attempt or desire to listen, I overheard from time to time the remarks of those who were passing near, and I was specially impressed by the floral instruction which I received for the first time on that occasion. One gentleman informed his partner that the berries of the Solanum were "a kind of Siberian crab;" another, that the Tulip, *Rex rubrorum*, was "a double poppy;" a third, that *Eucharis amazonica* was "one of those lovely orchids;" and a fourth (a lady) exclaimed in admiration, as she gazed upon a bush of *Cytisus*, "What a dear little duck of a young laburnum!" But there were other flowers that night, which, even in Flora's presence, were more admired than ours—heartsease and forget-me-nots in the blue eyes of Beauty, roses blushing and glowing on her cheeks, lilies and tulips upon her—

"Hands, lily-white,
Lips, crimson-red,"

much more fascinating than those which we showed in pots. In foliage we sustained a like defeat. They turned from our Croton angustifolium to the shining tresses of some Fair One with the Golden Locks, and they saw no charms in our Adiantum *Capillus-veneris*, when compared with the maiden-hair of Venus's self.

The ball was nearly over. The carriage-lamps of the departing guests were gleaming amid our ancient oaks, as though some of the planets had come down to earth, and my own special lamps, within their bright pictorial cases, were also beginning to take their departure, when, as I retired to my ambuscade, on hearing voices, the guardsman, with Lady Alice on his arm, approached, and stopped close in front of it. I saw them through the leaves, the handsomest man and the most beautiful woman of all who met there that night. It was not only that they were both tall and graceful in figure, with features regular and refined, the eyes bright, and the cheeks glowing with all the healthfulness and hopefulness of youth; but there was in both faces that which I would term heart-beauty; there was goodness, gentleness, and truth. And yet, as "these two, a maiden and a youth, stood there, gazing," or seeming to gaze, upon an orange tree covered with its blossoms, I noticed upon both the expression of a strange and sad perplexity. For a while they were silent, and then the soldier said: "I am going in a few hours. I must speak to you. Would you—would you exchange *those*" (and he looked at the roses in her waving golden hair); "would you change them for *these*" (and he touched one of the orange-flowers)—for my sake—for me?"

I shall never forget that beseeching voice. It thrilled me through with the anxiety which it expressed, and I leaned forward to hear the answer: "I—I—I believe that I am engaged to the viscount." Then for a few awful seconds there might

have been in that conservatory no living soul, for there was no sound save of distant music, faintly heard from, the ball. At last he spoke with a great effort: "I have no right to ask you; but do you love him?" and she, in a tone which cut my heart like a knife, replied, "My father, the duke, wishes me to marry him." "Not," he said passionately, "if you do not love him!" and then there was another dreadful silence, broken by these hopeless, whispered words, "I cannot, I dare not, disobey the duke. Some one is coming; we must go."

I do not think that the guardsman knew quite what he was doing, but what he did do was this: he plucked a leaf from the orange tree, and gave it to her, and said, "If ever there is hope for me, or I can help you, send me this leaf."

Then others joined them, and they went their way. I stayed there, mute and motionless, thinking what cruel tyranny it was to crush those young loving hearts, until a footman came to say that the ball was over; and then I hurried home, weary and sorrowful; and I remember that before I went to bed that night I prayed that she might send him the leaf. But Mrs. Oldacre, from whom I never had a secret, declined to regard the circumstances as becoming subjects for doubt or petition. She sniffed at my solicitude with a grand disdain, "because I know," she said, "that he will have the leaf."

(To be continued.)

S. R. H.

PUBLIC GARDENS.

BIRMINGHAM BOTANIC GARDEN.

In extent, and in various other ways, this is as unlike the establishment a town like Birmingham should possess, as anything can be. Like many other botanic gardens, this was spoiled at the outset by being made too small. It is only twelve acres, and it does not look more than six. When people make a park their ideas seem to expand a little, but few of the originators of our provincial botanic gardens seem to have known that a worthy botanic garden cannot be made on a space little larger than a good cricket-ground. There are at the very least five hundred species of trees and shrubs in the country which no garden presuming to call itself "botanical" should be without; and if we would only just consider how much space it would take, not merely to preserve these in a living state, but to fully develop and show their beauties, there is every probability that we should rise higher than the old, narrow, feeble idea entertained with regard to a botanic garden. We shall never have botanic gardens worthy of the name, till it is seen that the highest office of a botanic garden in a cold or temperate country is to treasure the vegetation of cold and northern climes, and that even the noble hardy oaks alone require for their fair development a larger space than some provincial botanic gardens occupy.

Apart from the great difficulty of want of space, we were glad to see much improvement in the garden. There is, for example, a really fine warm conservatory, erected at a cost of £1,600, which is filled with noble tropical plants, and in every way highly creditable to the curator, Mr. Latham.

The water here is small and mean in the extreme. It should be drained off, and its site converted into a fernery, or something of the kind. Better do nothing than do anything meanly. And this, above all things, as regards water.

The garden is on the red sandstone; and a capital improvement has been effected in converting a kind of an old quarry into a large rock-garden and fernery. Much yet remains to be done with it; but it is, on the whole, a distinct step in advance, and very suggestive of what may be done in gardens lying over rock that comes near the surface. Properly adorned with suitable ornaments, and its surroundings perfectly in harmony, it may be made to form one of the finest rock-gardens to be found in any of our botanic gardens.

We were all the more pleased to see this desirable effort, from the woeful nature of the "rockwork" in the villa gardens round Birmingham. Horticulturally speaking it may be described as the City of Ridiculous Rock-gardens. The passion for the picturesque here finds vigorous expression in little and

nearly level surfaced walls and banks of the refuse of the furnace and the quarry. These may be seen in the greater number of the many suburban gardens of Birmingham. Occasionally the material of the rock-garden is beautifully variegated by what a person unacquainted with glass factories may perhaps be pardoned for describing as bottle-glass in a state of nature, and sundry other allied bodies, not the colour of any stone we have hitherto seen in rock-gardens, natural or artificial.

Seeing manifest improvement, and a desire to advance, one regrets to allude to one of the worst instances of vandalism that has ever been perpetrated in a botanic garden. Half a dozen years ago there was a fine collection of *Crataegi* here; they were a little too thickly planted perhaps, but very little care would have made the little grove something that any garden might be proud of. The trees were nearly forty years old, and consisted of unusually rare and valuable kinds. The collection was one of the finest, if not the finest, in the kingdom. Well, the trees have been cut down, burnt, and the site levelled for an archery ground! Yes, a collection, the growth of forty years, destroyed to make room for what is quite out of place in a botanic garden, now much too small, and which could be made with less trouble in any bare spot in the adjoining fields. Fancy the abolition of an acre of the cases in the British Museum for the sake of making a gallery for American bowls. Every kind of vandalism, however, is not tolerated, for, on a board on the lawn where this fine collection of exotic hawthorns once stood, it is written that any person seen taking or seeking for birds' nests, will be "expelled the gardens." Would that some similar caution had been exhibited on the fine hawthorns before their total destruction! A few more like clearances, and there would not be much occasion to placard warnings against bird-nesting.

ASTON PARK.

ASTON HALL is an old Elizabethan mansion, finely situated on a bold eminence near Birmingham. It is now used as a public museum. We will not enter beyond the hall, where there is written on brass:—

"Be it remembered that on the Twenty-second day of September, A.D. 1864, and in the Mayoralty of the Rt. Worshipful William Holliday, Esq., this Hall and Forty-three acres of land surrounding it, having been purchased by the Corporation of the Borough of Birmingham, were formally dedicated to the use of the people for their recreation, as a Free Hall and Park for ever."

The state of the garden or park round this old mansion is such as every person taking an interest in public gardens must regret. I have never seen a more desirable site for a public garden, or small park, the ground rolling grandly down from the crest on which the hall is situated, and one end of the terrace garden having a view over the country to the north of Birmingham, as commanding in its way as that which is obtained from the turrets of Arundel or the terrace at St. Germain. Yet, in point of keeping, the place looked, on the 21st May last, in a state much worse than that of the roughest tea-garden. The turf in parts seemed as bare as if it had been the favourite ground of Aunt Sally exhibitions. Withering shrubs, broken bottles, and weedy flower beds, are the chief impressions left by a visit to the grounds. Dirty paper lay about so thickly that it was blown into small drifts by the breeze. Indescribable filth was in the corners of the terrace garden. One unhappy flower bed was traversed by small walls of ugly rockwork, radiating from a flagstaff in the centre.

As for the landscape features, they are utterly neglected, though, properly handled, they would make the place a gem in its way—the ground is so favourable. Whatever the financial circumstances of the town may be, there can be no excuse for leaving Aston Park in its present condition. If Birmingham is unable to maintain the few flower beds at Aston Park in a decent state, surely the right course is to turf them up and devote the labour now wasted upon them to putting the grass, the most indispensable part of the park, in order. In all public gardens the rule should be, "Do not at all, rather than do meanly." Then, again, in the matter of waste paper, are there not sundry individuals, who energetically, and with

money in their purses, besiege every newspaper office for "waste," who would gladly contract for its removal from Aston Park? Indeed, in this way, the revenues of the town might receive a not unwelcome accession.

We have rarely, if ever, seen a city or town so utterly devoid of cheerful open planted spaces as Birmingham. Nowhere is there more evident the usual crop of large cities—a wretched deteriorating race, famishing, for want of God-given air, in narrow dirty streets; nowhere more evidence of "rapidly increasing prosperity," if the addition of any number of new, smoky streets be a test of it. Yet it cannot afford to keep this one park—mere garden in size compared with one of the London parks—half so neatly as the proprietor of the "Welsh Harp" or the "Rose and Crown" keeps his little flower-sprinkled domain!

NOTES OF THE WEEK.

— THIRTY-SEVEN THOUSAND persons are reported to have visited the Royal Botanic gardens and pleasure grounds at Kew on Whit Monday.

— A good specimen of the somewhat rare *Magnolia auriculata* is now in flower at Messrs. Osborn's nursery, Fulham, and there are also good examples of *Pavonia flava*, *P. discolor*, and *Berberis Wallichiana*, likewise all in blossom at the present time in the same establishment.

— AT a meeting of the British Anti-Tobacco Society the other evening, it was stated that £18,000,000 per annum are squandered on tobacco. The report deplored the increase in the consumption of tobacco in this country.

— Once a Week, speaking of an Eucalyptus, says: "The hollow trunk was sufficiently large to admit of three riders, with an additional pack-horse, entering and turning around in it without dismounting." This tree is reported to have been four hundred feet in height.

— The poorest flora in the world, says Nature, is probably that of the Island of St. Paul, in the Indian Ocean. It consists, as far as flowering plants are concerned, of six grasses, a sedge, a *Plantago*, and a *Sagina*. Of these the two latter only are undescribed species, and all the remainder have probably been introduced.

— We rejoice to hear that the great national exhibition of plants and flowers recently held at the Botanic Gardens, Manchester, originally suggested by Mr. Bruce Findlay, the curator, and admirably realised through the liberality and energy of the council, has been a most gratifying success. The receipts are no less than £2,010, and the net profit will exceed £800.

— The results obtained from the cultivation of gardens by boys at two schools, those of Eyemouth and Paxton, in the county of Berwick, are, says the Farmer, something wonderful. At Eyemouth the produce realised reached, in ratio, a value of £51. 8s. 6d. per acre; and at Paxton the boys obtained from their little plots a sum equal to £10. 1s. 4d. per acre.

— THE beautiful Tangier Iris (*I. tingitana*), found by Dr. Hooker and Mr. George Maw in North Africa, has recently flowered at Kew and Benthall Hall. It may be described as in colour not unlike the richly-hued Iris reticulata, but with a flower as large as the German Iris. It is a marked acquisition to our cultivated Irises, unsurpassed for beauty as many of them are.

— THE amount of timber land in British Columbia is estimated to cover about 100,000 square miles. In Alaska, it is said that 150,000 square miles are occupied with wood, and in Washington territory, Oregon, and California, about 105,000 square miles. Fires occasionally make sad havoc, but with such a space devoted to timber, little apprehension need be entertained respecting scarcity of wood.

— THE herbarium of Columbia College, New York, says *Hearth and Home*, is to have added to it the immense collection of Dr. Meissner, of the University of Basle. This herbarium contains 63,000 species, and is purchased for the college through the liberality of J. J. Crook, Esq. The present herbarium of the college is founded on the invaluable one of Dr. John Torrey, and is especially rich in typical specimens. With the proposed addition it will be the largest herbarium in the country.

— At a meeting held in Edinburgh the other day, a sub-committee was appointed to take steps for raising subscriptions to secure a granite pedestal for the monument to the late Prince Consort, and to lay out the garden, in which it is to be erected, in an appropriate manner. The Duke of Buccleuch has guaranteed the sum of £2,000 to the fund, which has already enabled the committee to commence the work. Princess Louise has subscribed £300 to the pedestal fund.

— AMONG fibre-yielding plants, the best is said to be New Zealand flax, which is reported to be stronger than any fibre used except silk. Silk will bear a strain of 34 lbs.; New Zealand flax, 23½ lbs.; Russian hemp, 16½ lbs.; common flax, 11½ lbs.; and *Agave americana*, 7 lbs. But in spite of these facts the export trade, as regards New Zealand flax, has dwindled down to almost nothing. In 1855 the quantity exported was valued at £2,020; and in 1864 it was only £162.

— THE opening of the People's Gardens, at Willesden, for the season took place on Saturday last, when about five hundred persons, all members, or visitors specially invited, were present. These gardens, the property of an association of working men, are about fifty acres in extent, situated on Old Oak Common, about five minutes' walk from Willesden Junction Station. They have been much improved since last year, and are now laid out with flower-beds, terraces, gravelled walks, cricket-grounds, and croquet-lawns. They will remain open every day, Sunday included, up to the end of September.

— ATTENTION is being directed, says *Public Opinion*, to the sanitary advantages of the cultivation of the sunflower in malarious districts. Many facts have been adduced to show that the sunflower has the property of purifying air laden with marsh miasm, absorbing a great quantity of moist and noxious gases, and exhaling an ozonised oxygen. Moreover, the French Sanitary Commission has lately pointed out that the sunflower is a most useful plant; it yields about forty per cent. of good oil, the leaves furnish an excellent fodder, and the stem, being rich in saltpetre and potash, makes a good fuel.

— MR. GEORGE MAW's fine collection of Saxifragas at Bentham Hall, near Broseley, is now very attractive, on account of the number of kinds that are in full bloom. There are in all about one hundred and thirty species, a good many of which have been introduced by Mr. Maw himself; and a good many of these are new kinds, discovered by that gentleman in his travels on the Continent and in North Africa. Among the most beautiful of the new Saxifragas now in flower are Mawiana, a distinct and remarkable kind, with a profusion of large white waxy flowers, and Wilkomeana, allied to the meadow Saxifrage, but larger and with a profusion of fine white flowers, in tufts from eighteen inches to two feet high.

— FEW spots are more attractive than Hampstead Heath, which was crowded during the Whitsuntide holidays. The improvement of the heath has already been commenced. The greater part of the area, as we have formerly mentioned, will be left in its wild state, but some of the sand and gravel pits will be filled up, especially where the removal of the soil has endangered the firs and other trees. With the object of saving some of these trees from decay, a small space has been fenced in round the firs near "The Spaniards," the "fantastic roots" of which will no longer be left bare; two small spots near "Jack Straw's Castle," about an acre in all, have also been enclosed and planted with evergreens and other shrubs.

— A COLLECTION of specimen orchids sold by Mr. Stevens the other day, contained some fine plants of Dendrobium densiflorum, one of which realised £9. 10s., a second £8. 10s., and a third six guineas. Caelogyne cristata fetched, in more than one instance, five guineas, and the lovely Saccolabium pinnossum, £5. At the same sale were also two new species of Disa; one, D. Barelli, is stated to have flowers as large as those of D. grandiflora, and of a bright orange ground colour, instead of pink as in that kind; the other, D. Herschelli, is reported to be a large-blossomed blue kind. The total amount of the sale, including some forty lots of the charming Aérides maculosum from the Bombay Presidency, was £380.

— IT is stated in the *Bath and Cheltenham Gazette* that Mr. Webb, of Reading, grows his filberts on the French system, and with excellent results. He often gets upwards of a ton of filberts per acre. The difference between his mode of cultivation and that usually adopted in Kent, is that Mr. Webb does not train or cut the bushes, which are allowed to grow as they please within the limits allotted to them. They are planted eight feet apart, and until they cover the ground vegetables are grown between them. He estimates seven years as the period required to bring them to profitable bearing, after which he realises on an average £100 per acre. The labour involved consists only in picking up the nuts as they fall, and no manure is required. Filberts will grow on almost any soil.

— NEARLY forty tons of new potatoes have now left the Scilly Islands, principally for London, and the same vegetable is being sent away from Penzance at the rate of five to six tons per day, but vegetables in Cornwall have not been so scarce and dear for many years. Cold winds and heavy showers of sleet and hail continue, and scores of acres of potatoes in the Penzance district, which, with an ordinary season, would have been in the market a fortnight or three weeks ago, are nothing like ready to take up. A large breadth of potato ground in West Cornwall will be very unprofitable this year; several acres have been ploughed up, so hopeless had the crops become through cold, and rain, and frost. Early cabbages are also a failure in most localities.

— OREGON, says the *Co-operative News*, is the healthiest State in the Union. The Willamette Valley has gained the appellation of the "Orchard of the World." Apples grow in such abundance that the limbs have to be propped up to prevent them from breaking under the weight of their burden long before the fruit ripens. Gloriosa Mundi often measures twenty-three inches in circumference, being larger than some men's heads. Luscious pears, that melt in your mouth, and sweet, juicy plums, are too plentiful to be a luxury. Among pears, single specimens of Uvedales St. Germain often weigh as much as four pounds each, and grapes from four to fourteen pounds per bunch. At this time of the year (middle of March) the orchards are in full bloom; the grass is a foot high; the delicious wild strawberries are ripening, and by the last of April will be in perfection. Currents, raspberries, gooseberries, blackberries, and huckleberries grow in profusion.

— It appears that the recent great storm at Madras has been most disastrous in its effects. Trees have been blown down, and the city itself, has not presented such a scene of desolation since the great cyclone in 1865. The river and islands were flooded, and some of the principal thoroughfares were almost impassable, owing to the number of trees and branches blown down. Mighty trees, indeed, that had battened with the storms of other years have at last been conquered, and lie, torn up by their roots, across the roads. The Park has suffered considerably, and the avenues on public roads cannot boast of a single tree that has not been dreadfully injured.

— A CORRESPONDENT of one of the morning papers thus describes a recent aspect of nature's flower garden in one part of Spain:— The country is bright with flowers, and the space along by the railway, of considerable width, is actually aglow with them. To the railway traveller who loves colour and brightness they are a source of infinite pleasure. Never did I see such an unbroken blaze of colour, sometimes running only in a band some ten yards wide by the railway, sometimes spreading out into the fallow beyond. First in brilliancy come the poppies, growing so thickly in places as to look like a scarlet flame as we rushed past them. These, with the exception of a little red star common in our own hedges were almost the only reds. In pinks there were masses of the little wild convolvulus, growing larger here, however, than at home, and there were clumps of madagas varying from white to deep mauve. In blue there were great masses of borage, the lighter blue of the cornflower, and in places a carpet of our garden minor convolvulus. In yellow there were the pale primrose of the kind which grows in our own cornfields, and the bright orange of countless flowers of a species of dandelion. In white there were masses of a small chamomile. The blaze of these colours was for miles uninterrupted, at times in masses of some particular sort, then a mixture of varieties and hue; but in all brilliant in the extreme.

THE FLOWER GARDEN.

SPRING FLOWERS.

THE season for clearing flower beds of their winter occupants has once more returned; and those who are anxious to have a display of beautiful flowers next spring, must now make active preparations so as to ensure a well-matured growth, as well-established plants will bear exposure best. Now, too, is the time to propagate a stock for next season; and happily the plants that are best adapted for that purpose are, with but few exceptions, within the reach of all. The gaiety of the flower garden in spring may be attained at a very trifling expense, as only plants of the easiest possible cultivation need be employed to produce it. Early flowers have charms unequalled by those of summer, over which so much labour, care, and expense are lavished. True, as regards early display, we have had, in some instances, extensive plantations of Dutch bulbs, such as Hyacinths, Tulips, &c., which, when used alone, are never very satisfactory; but if interspersed or associated with hardy annuals or evergreen perennial plants, and used in moderation, the result is effective and pleasing. Many are deterred from employing these hardy denizens in the decoration of our spring gardens from a labour point of view; but one man with half an acre of ground will produce a vast quantity of plants, and that too from the most simple and easily comeatable material. Be that as it may, it would be better to cut down the expense of summer bedding to one-half than dispense with spring flowers. We would thus be gainers both in point of effect and utility.

It requires a certain amount of judgment to part and prepare plants for the spring garden. To preserve uniformity of growth, the plants should be selected as nearly of a size as possible. Wall-flowers may be had from seed; and in the case of double and other choice varieties, which it may be desirous to propagate from cuttings, no time should be lost in having them inserted, so as to insure an early and consequently well-matured growth. In the majority of instances, a spare frame or hand-glass may now be commanded, which will greatly facilitate the operation. The best situation for them is a north border, and they should be inserted in finely-sifted soil and sand, previously rendered solid. The lateral shoots from the main stems should alone be chosen, and stripped off with a heel. They are not benefited by being trimmed with a knife; but may be dibbled firmly into the soil as they are separated from the plant, and well watered. Do not shade at all, but give an abundance of air during the night, to prevent drawing; and as soon as they will stand full exposure during the day, remove the lights. When well rooted, re-plant into the reserve garden, choosing a fully exposed situation; preserve compactness by stopping back strong shoots; bearing in mind that what stopping is done should be

immediately after the plants are established in the nursery lines, and that no after-pinchings should be practised, as it has a tendency to retard the blooming period. The same treatment holds good in respect to Alyssums and the perennial Candytufts or Iberis, &c. It may be added that in shady situations these plants will root without glass or other covering; but the process is much slower.

The Oxlip is one of the most useful of spring flowers, and at the same time one of the easiest to cultivate. Being, as everybody knows, indigenous to Britain, it is readily procurable in most districts, and should now be collected and divided into as many pieces as there are good crowns, and planted in a shaded situation, in a rich, heavy, retentive soil. Single white and purple Primroses are also effective, more particularly the purple one; as a rule, indeed, the single varieties are better for spring decoration than the double sorts, as they stand longer in flower, lift better, and are in every respect more manageable. Ajuga reptans rubra, a purple-leaved kind, which flowers in the greatest profusion in spring, is not at all a despisable plant, and should now be divided and replanted into nursery lines.

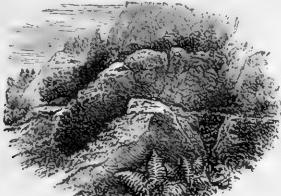

Amongst the most useful of spring flowers is the Pansy, a sufficient stock of which may be procured from those that are now being removed from the flower beds. Divide them into the smallest portions possible, retaining a root to each, and planting upon a north border in richly prepared soil. In the case of scarce or new varieties, propagate under a hand-glass, and shade from sun, selecting young growth void of pith, which roots best. These remarks also apply to the treatment to be carried out with the majority of plants now being lifted from the spring garden.

GEORGE WESTLAND.

THE ALPINE GARDEN.

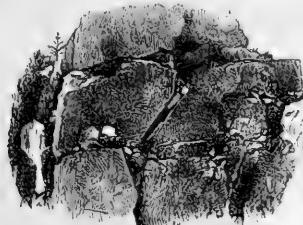

(Continued from p. 548).

We will now enter into particulars as to the various ways in which alpine plants may be grown, beginning with the best type of rock-garden—that in which, in addition to the low-lying, stony, and rocky banks and slopes, where numbers of hardy and vigorous species may be grown, there are miniature peaks, cliffs, and ravines, with perhaps bog and water. The

Right.

most usual and deplorable of the faults in making rockwork is that of so arranging the stones that they seem to have as little connection with the soil of the spot as if thrown out of a cart, indeed less so. Instead of allowing what may be termed the foundations, or apparent foundations, of the rock-garden to barely show their upper ridges above the earth, and thereby

Wrong.

suggesting much more durable ideas of "rock" than those arising from the contemplation of the bold and unnatural-looking masses usually seen, the stones are often placed on the ground with much the same idea that animates a bricklayer in setting bricks. The two accompanying cuts will explain

exactly what we mean; both are accurately engraved from photographs, both represent small portions of artificial rock-work; the ugliest of the two was much the most difficult and expensive to make. One well-selected stone allowed to peep from some gently rising isolated mound or open sunny spot,

and arranged as shown in the accompanying little cut, would produce a better effect than several tons placed as in the preceding one.

In dealing with the construction of the bolder masses of rock-work, we cannot have a better guide than Mr. James Backhouse. If we merely want a certain surface of rock disposed in a picturesque way, such details as these may not be worthy of attention, but if we wish our rock-gardens to be faithful miniatures of those wild ones which are admitted to be the most exquisite of nature's gardens, then they are of much importance.

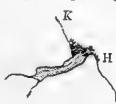

Comparatively few alpines prefer or succeed well in horizontal fissures. Those, however, which, like Lychnis Viscaria and Silene acaulis, form long tap roots, thrive well in such fissures, provided the earth in the fissure is continuous, and leads backward to a sufficient body of soil. Where the horizontal fissures are very narrow, owing to the main rocks being in contact in places, and leaving only irregular and interrupted fissures, such plants as the charming Lychnis Lagascae, Lychnis pyrenaica, and others, bearing and preferring hot sunny exposures, do well. But many plants that would bear the heat and drought, if they could get their roots far enough back, would quickly die if placed in such fissures, from the paucity of soil and moisture near the front; therefore it is usually better, in building rockwork with these fissures, to keep the main rocks slightly apart by means of pieces of very hard stone (basalt, close-grained "flag," &c.), so as to leave room for a good intermediate layer of rich loam, stones, or grit, mingled with a little peat. The

front view of such a structure would be as above—the dark spaces being firmly filled with the appropriate mixture of soil before the upper course of large rocks is placed.

As a rule, oblique and vertical fissures are both preferable to horizontal ones; but care should be taken with oblique fissures that the upper rock does not overhang. A plant placed at

Wrong.

Right.

J will often die, when the same placed at II will live, because the rain falling on the sloping face of rock at I will drop off at J, and miss the fissure J altogether, while that falling on the sloping face of rock at K will all run into the fissure II. There are, however, some plants, like the rare Notochlaena Maranta and Androsace lanuginosa, which so much prefer positions dry in winter that a fissure like J would suit them better than one like II. Such are rare exceptions to a general rule.

The best and worst general forms of steep rockwork we have tried are those indicated in the following figures. By making each rock slightly recede from the one below it, the rain runs consecutively into every fissure. Where the main fissures reverse this order, almost everything dies or languishes. Care should be taken to have the top made of mixed earth and

stones—not of rock, unless use is intentionally sacrificed to scenic effect. Vertical fissures (which suit many rare alpines best of all) should always, as far as possible, be made narrower at the bottom than at the top. If otherwise, the intervening

Right.

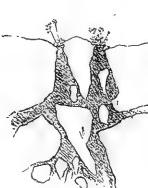

Wrong.

earth, &c., leaves the sides of the rock as it "settles," instead of becoming tighter.

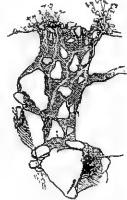

In the next figure, as the total mass of soil sinks, it becomes compressed against the sides of the rock; while in the other the soil leaves the sides of the fissures more and more as the mass sinks, and almost invariably forms distinct "cracks" (separations between the soil and rock) sooner or later. The same principle applies to small stones and fissures. To prevent undue evaporation in the case of such fissures, stones, larger or smaller, may be laid on the *top* of the soil, care being taken not to cover too much of it, to the exclusion of rain.

Right.

Wrong.

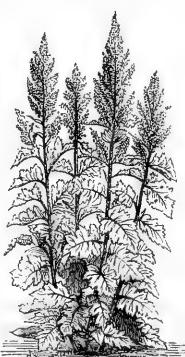

A properly formed
large fissure.

Where a large fissure exists, the smaller pieces of stone in it are on this account best placed with the narrowest edge or point upwards—not downwards. It will easily be seen that the tendency of the mixed soil, both as a whole and in each of its subdivided parts, is to become more and more compressed by its own weight and by the action of rain.

(To be continued.)

BOCCONIA CORDATA.

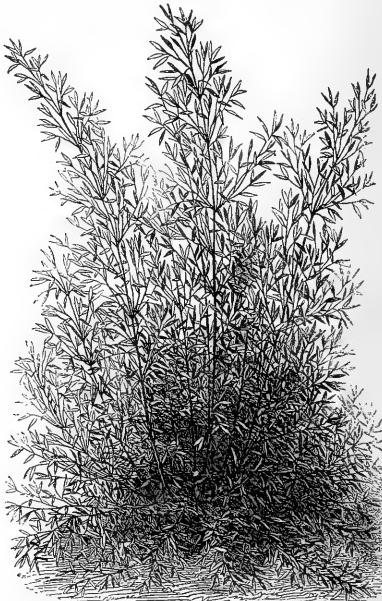

This is a fine plant in free soil, but comparatively poor in that which is stiff and cold. It forms handsome erect tufts from five feet to over eight feet high. The stems grow rather closely together and are thickly set with large, deeply veined, oval-cordate leaves, the margins of which are somewhat lobed or sinuated. The flowers, which are rosy-white and very numerous, are borne in very large terminal panicles. They are not in themselves pretty, but the inflorescence, when the plant is well grown, has a distinct and pleasing appearance. The plant is seen to best effect when isolated, and does well in ordinary garden soil or free sandy loam. It attains its greatest size when placed in the angle of two walls which shelter it from the north and east, which seems to indicate that it does not like sudden changes of temperature and light. It should not be moved too often. It will prove a good thing for associating with other fine hardy plants in bold groups, and is also worthy of a place among the taller plants in the herbaceous border. It is easily increased by seed or by means of careful division. It is a native of China.

Bocconia cordata.

BAMBUSA AUREA.

A very hardy and graceful Chinese species, differing but slightly from *Bambusa viridi-glaucescens* in size and habit, and forming elegant tufts with its slender much branched stems, which attain a height of from 6½ feet to 10 feet, and are of a light-green colour when young, changing into a yellowish hue, and finally becoming of a straw-yellow when fully grown. The leaves are lance-shaped, acute, light green, and are distinguished from those of *B. viridi-glaucescens* by having their under surface less glaucous, and the sheath always

Bambusa aurea.

devoid of the long silky hairs. This, as yet uncommon bamboo, is one of those hardy species that may be tried with confidence in our southern and mild districts where *Bambusa falcatum* succeeds so well.

THE HOLLYHOCK.

The hollyhock is one of the noblest of hardy plants, but fashion, ever variable, combined with the rapid improvement of late years in Pelargoniums and other dwarf bedding plants, has driven it out of the parterre or geometric flower garden. But still there are many positions in almost all gardens where a few hollyhocks would add immensely to the general effect. For breaking up ugly lines of shrubs or walls and for forming backgrounds, their tall, column-like growth is eminently fitted. Twenty-five years ago they were common in nearly every cottage garden, their stately stems towering up half as high as the cottage itself. Cottage bee-keepers would do well to grow a few hollyhocks, for bees are fond of working amongst their flowers, and they yield them a rich harvest of honey when the honey from other flowers has been gathered. The bark of their stems produces a strong fibre that might perhaps be utilised by the manufacturer if obtainable in sufficient quantities. It is also said to yield a blue dye, equal to indigo. If the seeds of hollyhocks are sown in autumn as soon as they are ripe in a box or pan in heat, and potted off and grown on in a pot through the winter and planted out the following April, they will flower the same summer and autumn. To obtain fine flowers it is necessary to treat them liberally. Deep cultivation, a liberal supply of manure, frequent waterings in dry weather, with occasional soakings of liquid manure, will alone secure fine spikes and well developed flowers. If grown for exhibition, the flowers must be thinned to give room for individual development, and the spike shortened so as to have all the

flowers open at the same time, and they must be shaded from bright sunshine.

I have hitherto only spoken of seedlings, but all the choice named varieties are propagated by cuttings. There are various ways of doing this, but the following plan is as far as my experience goes, the most successful:—In July or August, when the shoots on the sides of the main stems begin to feel firm, prepare a frame for the cuttings in the following manner: Almost any position will do for it; place on the bottom a layer of coal ashes to keep down worms, then about two inches of thoroughly decayed manure, next two or three inches of fine-sifted soil, with a good sprinkling of sharp sand on the top, and make all rather firm with the back of the spade, give a gentle watering, and leave it to settle for an hour or two. In taking off the cuttings select the moderately firm side-shoots, label each kind, and tie it up separately to avoid mistakes. Each joint with a dormant bud in the axil of the leaf will make a cutting; leave about half an inch of the wood above the bud, and about an inch and a half below it; cut off the leaf, but leave on the stalk, it will help to support the bud for a few days; plant the cuttings in lines across the frame by pressing them into the bed up to, but not burying, the bud. After all are planted give a gentle sprinkling, to settle the sand round them; shade from bright sunshine, and keep close. Whenever the sand looks dry dew them over with a fine rose about ten or eleven o'clock in the forenoons of bright days. In July and August they may be struck with the greatest ease in this way. If only a few plants are wanted, hand-lights may be used. A two-light frame will hold about a thousand cuttings. After August it is best to put the cuttings into pots, as it may be necessary to give them a little bottom heat. They may also be propagated in the spring by potting up strong, old plants in the autumn. When placed in a gentle heat in February they will throw up lots of young shoots, which, when far enough advanced, may be taken off, put into small pots, and plunged in a gentle hotbed. They may also be increased by root grafting—that is, by grafting pieces of choice kinds on to roots of strong young seedlings. This is an expeditious way of making nice young plants. It is always a safe plan to strike a few cuttings every year, as strong young plants planted early in April in well-prepared ground will generally make the finest spikes. If fine spikes and fine flowers are wanted, only one spike should be left on each plant.—E. Hobday, Ramsey Abbey, in "Field."

THE IVY AND ITS USES.

Apart from the fact that the Ivy is the best of all evergreen climbers, it is the best of all plants for softening the aspect of town and suburban gardens in winter, not to say all gardens.

To rob the monotonous garden railings of their nakedness and openness, the French use it most extensively, so that even in the dead of winter it is refreshing to walk along by these. And if it

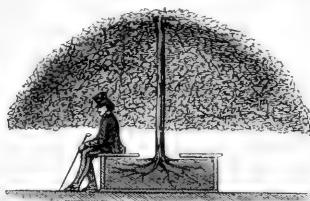

Garden Railings densely covered with Ivy.

does so much for the street, how much more for the garden? Instead of the inmates of the house gazing from the windows into the street swarming with dust, or splashing with mud, a wall of verdure encloses the garden; privacy is perfectly secured; the effect of any flowers contained in the garden is much heightened; and lastly, the heavier rushes of dust are kept out in summer, for so admirably

are the railings covered by planting the Ivy rather thickly, and giving it some rich light soil to grow in, that a perfectly dense screen is formed. Railings that spring from a wall of some height around the larger houses are covered as well as those that almost start from the ground. Frequently the tops of the rails are exposed, and often these are gilt, while wire netting on the inner side supports the Ivy firmly.

If there are tall naked walls near a Parisian house, they are quickly covered with a close carpet of Ivy. Does the margin of the grass around some clump of shrubs or flower beds look a little angular or blotchy? If so, the gardener will get a quantity of nice young plants of Ivy, and make a wide margin with them, which margin he will manage to make look well at all times of the year—in the middle of winter when of a dark hue, or in early summer when shining with the young green leaves.

When the Ivy is planted pretty thickly and kept neatly to a breadth of, say, from twelve to twenty inches, it forms a dense mass

Section of Circular Bower formed of a single plant of the Irish Ivy grown in a tub.

of the freshest verdure, especially in early summer, and of course all through the winter, in a darker state. The effect of Ivy bands outside masses of gay flowers is excellent. They form a capital setting, so to speak, for the flower borders—the best, indeed, that could be obtained; while in themselves they possess qualities sufficient to make it worth one's while to grow them for their own sakes. In some geometrical gardens we have panels edged with white stone. These Ivy edgings associate well with the stone edgings, while they may be used with advantage in any style of garden. A garden pleases in direct proportion to the variety and the life that are in it; and all bands and circles of stone, all unchangeable geometrical patterns, are as much improved by being fringed here and there with Ivy and the like, as are the rocks of a river's bank.

It should be observed that an Ivy edging of the breadth of an ordinary edging is not at all so desirable as when its sheet of green is allowed to spread out to a breadth of from fifteen to eighteen inches. Then its rich verdure may be seen to full advantage. It

Variegated Ivy in Suspended Basket.

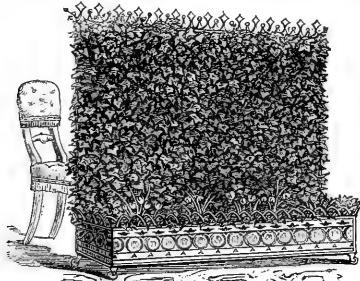

must of course be kept within straight lines if the garden be symmetrical: if it be a natural kind of garden, you may let it have its own wild way to some extent. I do not think I ever saw the scarlet Pelargonium to so great advantage as in deep long boxes placed against the wall of a courtyard densely covered with Ivy, and with Ivy planted also along their front edge, so as to hang down and cover the face of the boxes.

The Ivy may be readily grown and tastefully used in a dwelling-

house. I once saw it growing inside the window of a wine-shop in an obscure part of Paris, and on going in found it planted in a rough box against the wall, up which it had crept, and was going about apparently as carelessly as if in a wood. If you happen to be in the great court at Versailles, and, requiring guidance, chance to ask a question at a porter's little lodge seen to the left as you go to the gardens, you will be much interested to see the sumptuous sheet of Ivy which hangs over from high above the masterpiece. It is planted in a box in a deep recess, and tumbles out its abundant tresses almost as richly as if depending from a Kerry rock.

The Ivy is also used to a great extent to make living screens for drawing-rooms and saloons, and often with a very tasteful result. This is usually done by planting it in narrow boxes and training it up wire-work trellises, so that with a few of such a living screen may be formed in any desired part of a room in a few minutes. Sometimes it is permanently planted; and in one instance I saw it beautifully used to embellish crystal partitions between large apartments.

To make the Ivy edgings which are so abundantly employed in and around Paris, plants are easily procured in pots, and at a very cheap rate, at the markets on the quays, or of the nurserymen at Fontenay aux Roses, who every year grow it in large quantities. It is planted thickly in borders, and trailed along in strips from twelve to sixteen inches in width, according to the size of the beds. It is laid down with wooden pegs, a layer of earth being placed over the

Ivy Screen for the Drawing-room with Flowers at its base.

plants. When once planted, it only needs to be kept clear of weeds, and to be moderately watered. Under this treatment, it forms healthy borders the year after it is planted. In preparing the Ivy for growing against railings and trellis-work that enclose the various parks and gardens, it is trained carefully during the first one or two years, so that all empty spaces may be filled up. At the end of the second year, the railings will be completely covered, and for the future it is only necessary to keep it properly pruned.

Towards the end of the summer the propagation of the Ivy by means of cuttings is carried on. Three or four leaves are left on each cutting, and they are planted very thickly in lines in a half-shady position. When they have taken root sufficiently, which generally takes place in the following spring, they are transplanted into pots of four or five inches in diameter. Afterwards stakes are fixed along the lines of pots, from which are stretched lines of thin galvanized wire, and to this slender but firm trellis from three to five feet high the plants are trained several times during the growing season. At the end of the second or third year the plants are strong enough to be employed to cover railings, and for many similar purposes. The nurserymen in the suburbs of Paris generally propagate them by layers. For this purpose old plants are placed at a certain distance from each other, and are allowed to grow long. Pots from four to six inches in diameter are then plunged in the ground around, the Ivy being fixed in them by means of small pegs, one shoot in each pot. Afterwards stakes are placed in the pots, and the Ivy trained against them as it grows. When the layers are sufficiently rooted, they are separated from the old plants, and towards the end of the second or third year they are ready for use. If a wide belt of Ivy is desired, the young plants may be put in in two or three rows, as the French do when making such excellent Ivy edgings as are here described. In any case, after the plants are inserted the shoots must be neatly pegged down all in one direction. The French keep them the desired size by pinching or cutting the little shoots well in, two or even three times every summer, after the edging has once attained size and health. The abundant supply of established plants in small pots enables the French to lay down these edgings so as to look well almost from the first day. Ivy edgings and Ivy screens are making way in this country. Mr. Marnock has lately

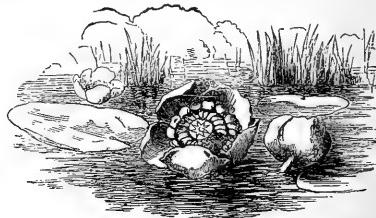

tried a large Ivy screen at Montagu House. The fact that Mr. Miller has succeeded in making very fine Ivy edgings at Combe Abbey of the common English Ivy gathered in the woods, suggests that many others among the numerous green forms of Ivies might be tried with advantage.

W.

HARDY AQUATIC PLANTS.

THE YELLOW WATER LILY.

AFTER the white water lily this is our most important native aquatic plant. It is worthy of a place in all artificial waters, grouped with the water lily, Villarsia, and the great yellow water lily, *Nuphar advena*, which is a native of America. The yellow water lily (*Nuphar lutea*) is a native of many parts of Europe and Britain, chiefly in slow streams and pools. The

The Yellow Water Lily.

flowers appear nearly throughout the summer; they are much smaller than those of the white water lily, and rise a little above the surface of the water. The dwarf yellow water lily (*N. advena pumila*) is a variety smaller in all its parts, and found in a few localities in Scotland. The yellow water lilies, like the white ones, are not seen to advantage when allowed to become crowded in the water.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Adonis pyrenaica.—A correspondent writes to me to say that the flowers of this plant, when true, are twice as large as those of *A. vernalis*, and what do they say to this?

The Californian Columbine.—This, the *Aquilegia californica* of our gardens and *A. truncata*, of some author, is one of the noblest herbaceous plants we have, and on that account deserves a place in every garden on very sandy loam, attaining a yard in height thereon. It is perfectly hardy. When the flower is turned upwards it presents a lovely combination of scarlet, orange, and yellow, gradually blending one into the other.—J. C. NIXEY, *Botanic Garden, Hull*.

The Rosy Canterbury Bell.—Those not already familiar with this variety of Canterbury Bell can scarcely imagine how beautiful it is. Not unfrequently the slightest variation from the usual colour of the species suffices to give a seedsman or nurseryman an opportunity to misname colours. But this is really of a distinct and beautiful rose-red, and it deserves to have a place in every spruce garden or herbaceous border. It is also a capital subject for naturalisation on chalky and warm soils.—H. V. H.

Agave elatior.—I am surprised this plant is not more grown. The true species is by far the finest of the genus. The flowers have the rich, pure blue of *Salvia patens*, and continue in perfection for a considerable time. It comes somewhat near, in character and merit, to *Dracocephalum grandiflorum*, and it succeeds best in boggy soil, and where its roots have plenty of room. Under such circumstances it spreads and increases rapidly.—J. C. NIXEY, *Botanic Garden, Hull*.

Allyssum olympicum.—I do not find this little gem as well known or so much appreciated as it deserves to be. It is the daintiest of all the Alyssums, and though not so conspicuous in blossom as some kinds, is worth really ornamental, while it is certainly the most delicate and graceful in habit. It loves a narrow sunny ledge in the rock-garden, and thrives best in a sandy, well-drained soil. Neither its delicate blossoms nor frail, silvery branches being very conspicuous at any time, it should have a position near the eye in the alpine garden.—C. C.

Banksia Rossii.—What lovely subjects these are for the embellishment of hedges, and even other kind of high walls, and yet how seldom do we see them taken advantage of! The other day at Whitley Abbey, near Coventry, I saw the wall of the abbey covered with two flakes of the white Banksia, reaching to the caves. This was in full-matured bloom when many of the hawkweeds hesitated to open their pearl-like buds under the fierce sultry rains and showers of hail, and when only the cosiest cottage-garden kindness had induced the monthly and other early roses to open their earliest flowers.—W. R.

The Plumbago Denticula (Dentaria eximia).—I have long known this graceful plant, but never till it was introduced as verbenaceous in the Botanic Garden, Islamic Garden, grown on a bank in a shade above the level of the eye. The effect was so much superior to what it usually is on the level ground, that I was quite surprised at it. The graceful head and toes of both foliage and leaves were seen better thus than when below the eye. We have a good deal to learn as regards the position with reference to the eye best suited for many small plants.—W. R.

THE FRUIT GARDEN.

A NEW FRUIT—DIOSPYROS KAKI.

A NEW specimen of fruit tree, and one which will thrive in the open air, is a rare piece of good fortune for cultivators in the temperate and western regions of Europe. It is, however, true, The Kaki, the fruit so much esteemed in Japan, Cochin China, and China—in fact, throughout nearly the whole of Eastern Asia—is introduced. We have seen it flower and fructify; we have tasted it. The fruit resembles a large apricot, and has also something of its flavour, with a little difference, however. The plant exists in the nursery of the Paris Museum, where we have watched it in its vegetation and fructification for the last three years. It was introduced into France some years since by M. E. Simon, consul in China, whose name is well known as an importer of plants and of animals, principally to the Jardin d'Acclimatation of Paris. The first fructification of the Kaki in the Museum took place in 1869. An interesting but impassioned discussion, of which we should speak with as much impartiality, consideration, and deference for the two adversaries as possible, took place on this occasion between M. Decaisne and M. Carrière. When the tree sent to the Museum by M. Simon fructified in 1869, M. Carrière, head of the nurseries, believed it to be the *Diospyros Kaki*, and spoke of it under this name. The exactitude of this determination was contested by M. Decaisne, who argued that the specimen in the Museum, native of Mongolia, and the north of China, was the *Diospyros Schi-tse*, described by Bunge in his "Enumeration of the Plants of the North of China," and not the *Diospyros Kaki*, a southern kind, which could not even ripen its fruit at Pekin, consequently with far less probability in Paris. Meantime the fruit of the *Diospyros* in the Museum had ripened; they presented a maliform profile, and M. Carrière, without ceasing to recognise in it a form of *Diospyros Kaki*, named the plant *Diospyros costata*.

Species or variety, it only remains for us to describe the plant we have seen in the Museum—*D. Kaki costata*, a shrub or small tree. The younger parts are of a greyish white, covered by a short and silky kind of tomentum, which almost completely disappears on the adult branches. The leaves are alternate, oval, suddenly rounded at the top, of from $6\frac{1}{2}$ inches to 10 inches long, and $2\frac{1}{2}$ inches to $5\frac{1}{2}$ inches wide, thick, of a dark green colour, smooth, and shining as if polished on the top, of a paler colour underneath. The flowers are single axillary ones, on a strong stalk of about half an inch long; they open towards the beginning of June. The fruit ripens in October or November, remaining on the tree until long after the leaves have fallen. It takes a fine red, almost orange colour, when it reaches maturity. It is covered with a transparent bloom, such as is seen on the grape. The fruit is pulpy, and reminds one of apricot marmalade, first of all very astringent, then sweet, of an agreeable flavour, not unlike the apricot, and which changes successively until it becomes in taste like a medlar. In its last state the pulp becomes of a reddish brown, and has but little taste. It has no seed—that is to say, we have found none in the different ones we have cut; in the interior are cells in the form of a star. The easy multiplication of the tree which has been obtained by layering or grafting on other *Diospyros* will soon cause the spread of this tree in gardens, where it will be of great value, on account of its fine form, its foliage, which resembles the *Magnolia Soulangiana*, and its beautiful and good fruit, which is of the size of an ordinary apple or a large apricot.—*Ed. André*, in "Illustration Horticole."

Diospyros Kaki.

PEACH CULTURE ON THE ANTI-MUTILATION SYSTEM.

The *beau-siléa* of a model-trained peach tree, according to the rules and regulations laid down by most writers with the utmost exactness, is a fan, perfectly exact in all its members; and in almost every standard work on fruit culture instructions are laid down to the very letter how to hew the living subject into shape—a kind of teaching which, we believe, has done more to lead the half-experienced astray in the culture of stone fruits than anything else. The extension system of training the peach consists in leaving the whole, or nearly the whole summer's growth of the tree, instead of cutting from one to two-thirds of it away at the winter pruning. Last summer, in walking through the peach houses in a large garden, and noticing some unusually vigorous young peach trees with shoots about four feet long as thick as one's finger, and which had been sedulously watched and pinched off all side shoots, we inquired what would be done with them in winter. "Cut each shoot back to about eighteen inches, perhaps," was the reply; and this represents the general practice. In the extension system, on the other hand, a reciprocal action between the roots and branches is encouraged by allowing both to extend themselves freely, thus utilising the natural vigour of the tree, and getting trees and crops in about half the usual time.

THE BORDER.

In a question chiefly relating to the branches and their training, some may wonder what we have got to say on this point, but we think it needful to say a few words. In the first place, as root pruning does not form such an important or indispensable part of the culture under the extension system, a wider border, say twenty feet should be allowed; and as the thorough maturation of the wood is a matter affecting the extension of all the branches, the texture of the soil is a consideration of some importance. We therefore recommend a border of the above width, $2\frac{1}{2}$ feet deep, with a dip from the wall, and a hard or firm soil. The peach will grow, and even thrive, in any ordinary garden soil that is not too stiff and retentive, nor, on the other hand, too light. If the soil is not naturally calcareous, well-broken-up lime scrapes may be added, and it is always safe and advisable to add as much good, fresh, turf-like loam as can be procured, if indeed the border cannot be formed altogether of such material. Whether the border be only partially or altogether renewed, the soil should not be moved about until it is in good working order—I mean in that condition in which it is quite safe to tread it with the feet without fear of its "baking." There is no doubt that the peach delights in a hard and firm soil, and makes the best-matured wood and bears the best fruit under such conditions. We therefore recommend the soil to be trodden pretty hard in making up the border, layer after layer. We have done this ourselves on every occasion, and speak from experience; but we were very careful to see that the soil was dry—just in that state in which gardeners prefer it for potting purposes. Had we to make a border when the soil was at all wet, we should probably not attempt to tread it at all; but when it is dry, soil is elastic, and there is then no danger in treading it firm. The bottom of the border should be beaten hardest, and the topmost layer need not be trodden at all.

PLANTING AND TRAINING.

October is the best time to plant, whether indoors or out. If the trees are procured from the nursery, an effort should be made to get them with from four to six perfectly ripened shoots upon them, of about equal length, and trained in the fan form. If the shoots are not ripe to the extremities, they may be shortened back as far

as the wood is green, or if any of them are much longer than the others, they may be cut in for the sake of balance. With these exceptions, as much of the season's growth as possible should be left. In planting a peach case or wall, the old plan of planting a dwarf and a rider alternately cannot be mended. Twelve feet is a proper distance between the trees, and when the riders come away eventually, to make room for the dwarfs or permanent trees, each of the latter, allowing the wall to be eighteen or twenty feet high, will have an area of about 480 feet to itself, which is not too much for any peach tree; better have a high wall than a long and low one, necessitating the cutting off of the best growths of the tree every year. "Give the trees room" should be the motto of every peach-grower. Of course, in houses of limited extent, when it is desired to have a peach and a nectarine, or more than one variety of peach, the trees must be planted closer; but it is preferable to have a house with only two trees than double that number if they have not ample room to extend themselves. In planting, make a semi-circular hole against the wall, about nine inches deep at the outside, and rising towards the wall, where the bale of the tree will be, to a depth of six inches from the surface. Place the tree in an upright position against the wall, taking care that the stem does not touch or come within about two inches of the wall at the surface of the ground; spread the roots out regularly in the fan form, cover them over carefully with the soil, and the operation is complete. After planting, nail or tie the shoots in as follows:—Supposing the tree to have six shoots, bring the two side ones down until they are nearly, but not quite, horizontal, and tie them; then divide the central space equally amongst the four remaining shoots, and you will have a rudimentary fan, from three feet to four feet in diameter, as a basis of future operations. In spring each limb will break evenly along its whole length, and they should be disbudded gradually until two or three shoots only, not including the leader, are left on the upper side of each limb; one at the base, and one or two between this and the point. These shoots will fill the spaces between the original limbs, and they are to be encouraged to grow as much as they will, and as the radius of the tree increases the earliest laterals of these summer shoots are to be laid in in their turn, on the same principle; and no stopping must be resorted to, unless it is seen that any particular member is getting too decided a lead, when the top may be pinched. In this way the energies of the tree will be expended in a proper manner, and large well-furnished trees, such as cannot be secured by any other mode of training, will be the result at the end of the season. It will, of course, be found that the bearing wood increases in quantity towards the extremities of the branches; but, as the peach never refuses to break abundantly even on the two and three year old wood if the trees are exposed to a good light, it will be found an easier matter to originate as many shoots as desired at the base of the tree the following season, and this must be attended to in disbudding, so as always to keep any space or bare limb covered with bearing wood. Winter pruning consists in thinning out the wood where too thick, but which should not be necessary if the disbudding has been properly performed, and shortening in any shoot that has been allowed to get greatly in advance of its neighbours.

RESULTS OF PRACTICE.

Were we not in a position to support our advocacy of the extension system by experience and success, we should not feel justified in undertaking the task; but we can point to examples. One of several peach trees—all of unusual size for their age—in a peach house here, is sixteen feet high and seventeen feet across, and is bearing fruit over that area. It would have been twenty-six feet across by this time had it been allowed to grow, or rather had there been room for it to do so; but a peach and nectarine were wanted in each division, and so much room could not be afforded. This tree, and the others, were planted, small trees with four or five moderate shoots upon them, in the spring of 1866. We have Cherry trees about the same age, and trained in the same way, of the same size and larger, and which have always borne a famous crop of fruit, equally distributed over their whole surface, showing the fallacy of the idea that the extension system of training leaves the bottom of the tree scant of bearing wood.—*J. S., in "Field."*

THE BLACKBERRY.

The blackberry bush—what a cad it is because it happens to be common in the vegetable world! If it were an exotic, growing here and there, and only growing at all when you nursed it, made much of it, manured it, and all the rest, then we should have it in our gardens, should write monographs about it, and call it after some tremendous botanical personage—nay, blackberry jam might be admitted to the awful society of Mayfair. And by-and-by it would be found out what education and good treatment would do for the

blackberry. The Swan's-egg plum was only a sloe once, and the Ribston Pippin no better than a crab apple. There would be blackberries, perhaps, bigger than the biggest mulberries, and they might even come to be worn upon ducal coronets in place of the strawberry leaf. But the poor plebeian blackberry is like the honesty and the patience and the simple courage that God has scattered so lavishly among what we call, and leave, "lower orders." It grows everywhere, in spite of contempt, neglect, and contumely; nobody ever gave it a lift, or sowed it, or propagated it; but when the hedge comes the blackberry vine shoots out its long stems, and sets to work to bear a banquet for the poor, who resemble itself. All over the Continent it flourishes; the hedges in Greece and Palestine are tangled with it; the plant twines about the ruins of Baalbec; it climbs the Indian hills; it went to America with the Pilgrim Fathers. To us it is in the botanical world what the sparrow is among the birds, and the house-fly among insects—our very humble friend, and so, of course, we snub it. It is condescension enough to mention it at all in a serious journal. What would be said if we descended upon the lovely purple flush of its modest blossoms, or the emerald of its swinging shoots in May, or the berries of scarlet and jet that come in the autumn, to make the birds fat and the boys and girls late for school?

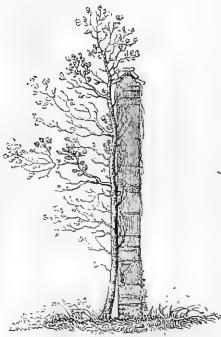

We use the above as a preface to a recommendation to our readers to try some of the noble varieties of American blackberries in our gardens. They are as superior to our common kind as the apple to the crab. The best kinds are the following:—Lawton or New Rochelle, a very large juicy berry, of a capital flavour when fully ripe; Wilson's Early, said to be harder than the Lawton, a very large, oblong oval, firm, sweet berry, ripening earlier than the other varieties; and Kittatinny, reported to be very hardy; fruit very large, sweet and firm, a good grower. We are not aware if these are in our fruit nurseries, but if not they ought to be. The improved varieties of American blackberries are grown in America to an extent of which we have no conception. The American blackberries are varieties of native species, and have nothing to do with our kinds.

NEGLECTED WALL TREES.

There is an old orchard of five acres, surrounded by a wall eight feet high, near where I live. The trees on this wall are each very like that represented in the accompanying woodcut. Nails and shreds

have long ago proved useless for such rampant giants as these; their strong arms are held to the wall by great wooden pegs. The curious thing is that the owner thinks he is deriving some benefit from having his trees against walls thus, and is often busy pegging them in, and otherwise attending to them.

He, of course, might as well not have them against walls at all. Though my orcharding friend's is an extreme case, there are too many gardens where great long spurs so abound on the trees that the owners get but little benefit from having them against walls. Need it be pointed out that trees are placed against walls for the purpose of giving them the benefit of the heat resulting from radiation from the wall's surface, and

that all walls on which the shoots are allowed to stray an inch from the wall than may be necessary, are badly managed? W. T.

IMPROVED FOREIGN PINES.

Or recent years some very fine imported Pines may have been noticed in Covent Garden windows, looking as fine as many of our best home-grown fruits. Recently Africa and South America have added to our stores of this fruit, the Pines from Brazil being generally of large size, three to five pounds weight, well matured, and brought over in good condition, some which we have tasted being really excellent in every respect. The Azores has put in a claim to our custom, and certainly with a prospect of deserving it, inasmuch as the fruit is not only large and of excellent quality, but is conveyed in a fresh and perfect state. The first batch, which was brought into Liverpool, conveyed in the pots in which the plants had been grown, was so fine, that the lot, upwards of fifty, was sold wholesale to one purchaser, at thirty shillings each. Since then many batches have been imported, and good prices realized for the fruit. Connected with these Azorean fruit we may give a little history.

Nearly twenty years ago, when Mr. Peter Wallace went out to take charge of the gardens of Signor Jose de Canto, Ponta del Gardo, St. Michael's, he took with him from Chatsworth a few dozen of small suckers of different kinds of Pines. These, under glass, with dung for bottom heat, thrived with great luxuriance, and in due time Mr. Wallace sent home an account of twelve of the Pines he had cut from the little suckers, the smallest Queen weighing 5 lb. 2 oz., the largest 8 lb. 4 oz., with Jamaiques and Montserratas of proportionate size, and Cayennes and Providentias of twelve to fourteen pounds each. The other day we saw a smooth Havaannah Pine from St. Michael's upwards of four pounds in weight, swelled perfectly flat and bright, and of that peculiar golden amber colour for which this Pine is remarkable when thoroughly matured. Four pounds is, however, a remarkable size for this variety of Pine, which here, in this country, is so small as not to be considered worth cultivation. It must be remarked that the Pines we have just spoken of were grown under the protection of glass, but Mr. Wallace stated that the glass was used more as a means of protection from the heavy storms to which the country is liable, than to secure additional warmth. Indeed, to use his own words, "the lights were pulled off in the morning, and on fine days were not returned until the evening, so that the Pines were in reality in the open air." He, however, attributed much of his success to the nice bottom heat and the ammonia-laden atmosphere with which he was enabled to surround his plants at night, and the moist, almost tropical atmosphere, and bright, uninterrupted light to which they were exposed throughout the day. One could not covet more suitable conditions, and therefore we need not be surprised at the splendid fruit which is now being sent over. Do what we may, we cannot command Pines of really first-class quality between October and May. We have not light enough to give flavour—and what is more insipid than a badly-grown Pine?—while our most perfectly matured summer Pines are not superior to these winter fruit from the little islands of the Azores. There are of course many other countries not more distant where the culture of fine Pines will prove easy; and as improved means of transit will no doubt help us, we may soon look for a regular supply of foreign pines in Covent Garden Market as fine in winter and early spring as the best summer products of our pinneries.

THE KITCHEN GARDEN.

THE CUCUMBER—ITS CULTIVATION AND USES.

(Continued from page 591.)

PLANTING THE CUCUMBER.

We have now, we think, said sufficient to enable everyone to prepare the material and make a hot bed, and therefore, considering that task completed, and the turf placed under the centre of each sash to receive the soil, we will proceed with the work of planting. For this purpose it will be necessary to place in the centre of each light about a bushel of the selected compost, drawing it up into a cone about a foot wide at the top and the same distance from the glass. Then presuming it to have attained the required temperature, 75° to 85°, take your plants and, turning them out of the pots, plant them in the centre of each hill, drawing the soil up to within an inch or so of the cotyledons or seed leaves. If the plants are strong, which they will be if raised as directed in a subsequent page, the roots in the course of a week or so will be showing through the soil, and then it will be necessary to top or stop the plants. Some do this at the first leaf, but we prefer to stop at the third or fourth leaf, so that when the plants break there may be three or four branches to furnish the frame at once. If the variety is a moderate growing one, two plants may be planted to each sash, but if a strong-growing kind then one plant will be sufficient. The second stopping need not take place until each shoot has made six to eight leaves, and then when the next breaks, fruit is sure to be shown. Train the branches regularly, thinly pegging them down as you proceed, but take care to have no more branches than there is room for the leaves to develop themselves in a proper manner. When the plants show fruit, the branches in the early part of the season up to April may be stopped one leaf before the fruit, but later they may be pinched backed to the fruit.

While, however, the branches are progressing the root will progress also, and, therefore, it will be necessary to have a supply of warmed soil ready to apply to the roots of the plants. This may be heated outside, but a very good plan is to keep some soil around the sides of the frame or pit, so that it may be in a fit state at all times to place upon the roots; this may be done twice or thrice a week; indeed some fastidious cultivators make it a rule to examine the plants every morning, and if a root is showing through they place a little soil upon it. Hamilton, a most successful grower, squeezes the soil between the hands into little compact balls and places them upon the roots, and then fills up the interstices with fine soil. This may be a good plan, but certainly it is not a necessary one. The earthing of the roots will continue until such time as the frame is full of soil. Here, however, we may take occasion to remark that the Cucumber will flourish in a much smaller quantity of soil than most people consider necessary. We have had in mid-winter plants in as fine a condition as possible, ten to fifteen feet long and strong in proportion, and still all they had to grow in was contained in a pot fifteen inches in diameter, and about the same in depth. Therefore, in earthing the Cucumbers, it will not be necessary that the soil exceed a foot in depth at the centre of the frame, sloping off to six or nine inches at the sides. The watering of the plants will require to be regularly attended to, but the quantity necessary will depend upon the weather. If clear and bright, three times a week may not be too frequently to water at the root; but if dull, once a week may be sufficient. At any rate, take care to sprinkle the plants and bed early in the morning, and also again at the time of shutting up for the night—say two o'clock in the afternoon, until March, and then just before the sun leaves the frame. The water for this work must be clean and warm, not less than 80°, and the quantity used for sprinkling should be sufficient to damp, not to dash the plants and soil. Water at the root may be given in tolerable quantity—say sufficient once a week to wet the soil to its whole depth—but at other times, after a bright sunny day, sufficient to wet the soil two or three inches deep. The great point of success is water of the proper temperature and of good quality. Of course, rain water is the best, but if that cannot be obtained, then soften the spring water by adding an ounce of guano to each three-gallon can. As a rule,

Girdling Trees to Produce Fruitfulness.—I think it is not generally known that girdling apple trees will cause fruitfulness. In the spring of 1869, a young one in the orchard of a friend of mine was full of bloom and promised a rich harvest. A gentleman, who happened to be stopping with him at the time, told him that if he would have a crop of apples he must girdle his trees. The idea seemed preposterous, and the owner urged that to girdle them would kill the trees. But the gentleman insisted that that was the only way by which he could get a crop, and that he would pay for all the trees that were injured by the operation. But my friend being a cautious man, and not daring to venture far on untried ground, simply girdled a branch or two here and there, which he thought might be cut away in case the girdling proved fatal. But to his surprise the girdled limbs immediately commenced forming a new bark where the old one had been removed. The blossoms on those branches set fruit, and in the autumn bent under the weight of luscious apples, while those trees and branches not girdled scarcely produced enough fruit to pay for picking.—*American Paper.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Duration of Pears on the Quince.—Can you give me any information as to the time pears will live on the Quince stock? Some of mine, aged about ten years, seem inclined to perish.—**GUILDFORD.**—[There is, we believe, good evidence to show that pears will live nearly, or quite, half a century on the Quince stock; on suitable soils, of course.]

Summer Pruning of Fruit Trees.—I am, as advised by my fruit book, pinching my trees to keep them in shape. What of the young wood is left by the means I send you a specimen. Am I pinching too short?—**AN AMATEUR.**—[Yes, much. No fruit-free shoot should be pinched at less than five or six leaves from the base of the current year's wood.]

Heating Vine Borders.—I shall be much obliged if you or any of your readers can give me a little advice in this matter. I am advised to heat and ventilate my new border; but some of my neighbours get very good grapes without doing so.—**EDG.—**—[It is a vexed question. Mr. Fowler and other good grape-growers hold it necessary to warm the borders artificially. Mr. Miller, of Chelmsford, not only does not heat or ventilate, but does not cover his borders in the winter. We should say, if you are an amateur, and only growing grapes on a small scale, make as good a border as you can, but neither heat nor ventilate it.]

Orcharding.—The present fickle spring confirms an opinion which I have for some time entertained as to the value of two comparatively little known varieties of apple—i.e., Lodgemore Nonpareil and Bess Pool—for planting in exposed situations. Not only are these excellent in the quality of their fruit, but they have a peculiarity which enables them to set their fruit under most unfavourable circumstances. They will commence to generate until nearly a month after other varieties planted in the same soil, with the result that the blossom. Their blossoms (May 16th) have not yet begun to open, and have in consequence escaped the blighting north-easters experienced lately. The Lodgemore Nonpareil is the highest flavoured dessert apple with which I am acquainted, and as handsome as it is good. Bess Pool, a larger fruit something like a Ribston Pippin in appearance and flavour, but with more Russet on the skin, keeps till April, and has the same useful propensity as its buds to cover till winter is nearly past. Any person not familiar with these kinds, coming into an orchard in April, would imagine the trees kind to be dead, so backward are they.—**E. T., in Field.**

ever, we do not recommend manure water for frame-grown Cucumbers. Generally they suffer more from the richness of the bed than from any necessity for manorial assistance; and, therefore, manure water, if used at all, will certainly not be required until such time as the plants begin to fail by heavy fruiting, then a soaking of weak guano water may be permissible, and not bad practice.

The temperature of the Cucumber frame or pit should not fall much below 65° with air by night, and may rise to 75° or 80° by day; and even to a higher temperature when the frame is shut up, after sprinkling in the afternoon. This is the time when rapid growth takes place, a brisk and moist temperature with a gentle circulation of air being necessary to promote the best growth in this class of plants. A.

(To be continued.)

FORMATION OF GARDEN WALKS.

In the formation of the kitchen garden it is always desirable to have the outline as nearly square as possible, and if it is not square, make as much of it as you can into that form, and use the outer portion for miscellaneous perennial crops, such as asparagus, seakale, horseradish, strawberries, rhubarb, herbs, and fruit trees. Then if the garden is not of a very small size—an acre or more—divide the square into four equal portions, not only because it will look better, but also as it affords the best means for systematic cultivation and cropping. These quarters should be intersected by gravel walks ranging in width from three feet, which should be the minimum, to six or seven feet, according to the size of the garden. Nothing looks so “pimping” and commonplace as narrow, uneven, or ill-formed walks. However well formed a garden may be in other respects, bad walks always spoil it.

In forming walks it is by no means necessary to go to the usual extravagance of making them a foot or more in depth. If rough material of any kind—gravel, brick rubbish, stone, clinkers, or even large cinders—can be procured, break it to the size of walnuts and then make it into lime concrete. The best way to do this is to first lay down upon a hard surface a three or four inch layer of the broken material, say three barrows loads; then, in the middle, put a barrowful of fresh lime and cover it with three more barrowfuls of stone. Proceed in this manner until the necessary quantity of material is provided, then pour sufficient water upon the first heap to slack the lime, and as soon as it begins to steam mix the lime, taking care to break the lumps, and stir together to the consistency of thick mortar. As fast as it is thus prepared lay it down to the thickness of three or four inches, making it quite firm and smooth as you proceed. Lay over this a coat of gravel half an inch thick, make it quite level, and leave it rough until it has had a good shower of rain, then roll, and you will have as good and cheap a walk as it is possible to form—and a walk, too, that cannot wash away, however heavy the storm may pelt. Before, however, the walk is formed it will be necessary that proper edgings should be provided. In point of appearance nothing can exceed box; but it is liable to be scorched, as thousands of yards frequently are upon sandy soils; it requires frequent relaying to keep it neat, and forms, moreover, a snug retreat for snails and other garden pests. We, therefore, prefer stone or earthenware tiles of some kind, and though they may be a little more expensive at the first, their permanency, if of good quality, renders them the cheapest in the end. These, of course, must be laid with perfect accuracy; that is, the ground must not only be perfectly solid and even from end to end and from side to side, but the tiles must be kept in perfect line in regard to height as well as to straightness. The tiles should be properly fixed prior to laying the walk, and then the concrete will keep them firm.

If the garden is level it may be necessary to form a drain or two at the lowest points, in order to take away the surface water speedily from the walks; but whether it will be necessary to connect these drains with the main drain will depend upon the nature of the subsoil. If the latter is porous or sandy, a cesspool to each grating, a foot or eighteen inches square and two or three feet deep, will be ample to take the water away, but if the ground is heavy, then it may be necessary

to connect the cesspool with the drains of the garden. In such an event take care that the cesspool catches the silt and soil, and that the water does not flow into the drain except by an overflow from the cesspool. If this provision be not made, the drains may soon be silted up, and rendered useless. There is yet another advantage of edging garden walks with some indestructible material, and that is, that for the purpose of destroying weeds, they may be salted or scalded, without either remedy doing any injury to the adjoining plants; indeed, in the course of a few months the walks may become so thoroughly impregnated with salt that no weeds can grow upon them—a great point gained. P.

RAILWAY EMBANKMENT CULTURE.

I HAVE often thought that the slopes of the railway embankments in this country, especially in some counties, might be turned to good account by cottagers residing near them. Found, as they often are, in some of our richest valleys, they would, without much trouble in regard to preparation of soil, afford a capital situation for the culture of choice fruits. The aspect of many of them is everything one could wish, combining at the same time shelter with plenty of sun, and they are so curved and otherwise screened as to enclose a temperature scarcely found in any other position out of doors. I believe, therefore, that there are some places in this county (Cornwall) where an apparatus might be erected for forcing fruits for the London markets, and prove a profitable investment. It would certainly be so as regards grapes. The cottager, with the help of the “ground viney,” could, with very little trouble, grow grapes for local markets. With a little expense, in the shape of trellises, peaches, nectarines, plums, pears, and cherries could be grown in perfection. Figs, too, could scarcely be planted in a better situation out of doors than in some of these places. Perhaps, however, they should be planted, say six feet up the embankment, where they would probably fruit better than in richer soil. The embankment would serve the purpose of a wall, while the roots of the trees would flourish in the rich soil beneath. Peas and scarlet runners could also be trained up these banks. Cucumbers could be grown by the million in the summer months by making little beds of good compost. Here and there over the slope vegetable marrows might be grown in the same way, and would be productive. Herbs of all kinds would answer. What an aspect some of those slopes would give for growing tomatoes! Digging out pits sixteen inches square, and filling them with stable dung and loam well rotted together, would be all the preparation required. The plants would grow down those slopes, and a few pegs and a little pruning now and then, would be all the after trouble. In the growth of cucumbers, vegetable marrows, and tomatoes, a frame and a hot-bed would be required to raise the plants in spring; many cottagers, however, already possess these essentials, and also the amount of skill and care to use them. Besides rendering the appearance of the slopes more pleasant, and increasing the pecuniary advantages of the cottage, the encouragement given by local exhibitions all over the country would be met by finer displays of fruit, if not a greater variety, than is at present seen at those shows.—H. M., *Enys, in “Gardeners’ Chronicle.”*

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Summer Spinach.—Will any of your clever kitchen gardeners tell me how to secure a regular supply of good spinach during the heat of summer? I want a large and a constant supply, and have hitherto generally failed. My soil is a dark rich loam.—D. S.

Marquis of Lorne Cucumber.—This gained the first prize the other day at Reading. The specimens shown were particularly handsome, and though only eight days old, measured over two feet in length. They were grown by H. H. Gardner to Miss Crawshay, Caversham Park. This variety was also much admired at the meeting of the Bavarian Horticultural Society, held at Munich, on the 22nd ult.

Watercress.—Can you inform me how I can grow watercress in a small garden?—H.—[For a small garden your best plan is to conduct a little stream of water through a small, level, puddled trench, so as to get an inch or two of gently flowing water over the roots of the cress. The watercress, like Uncle Sam’s gunboats, will crawl about anywhere where there is a little dew. We have grown it in slightly excavated beds, with stiff clay puddled at the bottom to retain the water in dry weather. It would grow well in any soil which could be kept well moistened, though by no means so well as when placed directly in the water.]

Moss and other Weeds on Walks.—If your correspondent, “T. N.” (p. 599), who asks what will destroy moss and weeds on walks in the best and cheapest way, will try the following, he will have his desire accomplished.—Mix in a large three-gallon watering can, containing twenty pints of water, one pound of oil of turpentine, stir it well, and water the middle of the walks, so that two or three drops of the liquid will fall on each square foot. It should only be applied to the walk when the grass is dry, and it should be applied from the centre to the side, literally along the walk. In two or three days grass will have disappeared.—R. B., Leamington.

THE GARDENS OF ENGLAND.

HIGHCLERE CASTLE—THE PARK AND GROUNDS.

THE RHODODENDRON SEASON.

The Rhododendron has assumed a degree of prominent importance among our ornamental shrubs which its splendid and profuse bloom and its fine evergreen foliage fully justify. The introduction of new species, and the successful practice of hybridization, have imparted to this handsome shrub its present great attractiveness and horticultural interest. It is indeed difficult to believe that many of our most enthusiastic horticulturists—both amateurs and professional gardeners—recollect the time when the old Rhododendron ponticum, with its pale lilac blossoms and sombre foliage, was the only plant of the genus to be found in our gardens. Then came the introduction of the Indian tree Rhododendron, with its magnificent blossoms of deep sanguineous scarlet, to which our botanists gave the name of *Rhododendron arboreum*. What a priceless addition to our shrubberies would this glorious plant have been if its constitution had but proved sufficiently robust to bear our climate!

and most profusely bloomed plants are allowed to appear; still, the canvas covering of the fairy-like scene is not, after all, the blue spring sky; and notwithstanding all the ingenuity of art lavished upon the variations of level and on the undulating walks, and in the temporary turf carpeting, from which the flower-weighted shrubs seem to be naturally growing, a wish creeps over the mind, and such groups of glorious shrubs clothing natural hills and vales with just such an avalanche of floral beauty—but the vain wish is dismissed with a sigh, as an unsubstantial dream.

I have often so dismissed it as one of the beautiful impossibilities of the imagination, and yet, the other morning (May 25th), I found it realised—even more than realised—in the woods and valleys of Highclere. It is true that the present is not a fine Rhododendron season, nevertheless, the vast extent of the plantations, and the profusion of bloom, though inferior in lavishness, as I was informed, to that of previous years, was, perhaps in its less overpowering prevalence of bright tones of purple, crimson, rose, cream, and violet, more favourable to really artistic effects in the horticultural landscape than denser masses of floral colour would have been, where no subdued and interblending green would have been visible, to sober down

Highclere.

Unfortunately it was not "hardy," and when admiring crowds went to see the fine specimens of it in Mr. Knight's conservatory, with trunks like those of young forest trees, the general admiration was sadly tempered with regret. Fortunately, the system of hybridization had successfully set in, and the joint offspring of the old hardy species and the glorious new introduction proved more or less able to bear our treacherous climate; while many new and brilliant shades of colour in the flowers also resulted from the new alliance. These crossings with the *Rhododendron arboreum*, and also with an American species, *R. catawbiense*, marked an entirely new phase in Rhododendron culture; and the subsequent exhibitions, by Messrs. Waterer, of the magnificent new varieties, in vast numbers, each plant rivalling its neighbour in brilliancy of colour and profusion of bloom, will remain on the records of horticultural progress as one of its most brilliant epochs.

The Rhododendron shows in the gardens at South Kensington and Regent's Park have long been kinds of floral festivals each successive spring, not only among true flower lovers, but among the general public, who never fail to hail these displays of floral luxuriance, with their gorgeous colours of a thousand shades and gradations, as among the impatiently-expected treats of the early part of the London season. Yet, beautiful as are these annual displays, composed entirely of selected specimens, in which none but the finest grown

the over-gorgeous colouring of the flowers. At all events, the effect was ravishingly beautiful, without more profuse bloom, especially round the lake, in the waters of which the forms and colours of the Rhododendron woods were reflected as in a mirror. The roads through the four thousand acres of wood and park are, indeed, bordered in many parts with Rhododendrons for long distances, and in the congenial soil of the place they have attained a height of from twelve to fifteen feet; many of the more freely blooming varieties forming dense masses of crimson, violet, or white. Highclere is, in fact, one of the places where the new kinds were first thoroughly appreciated, and planted out in great abundance; several of the most favourite of the varieties having been raised there, as *R. altissimae*, *Victoria*, and several others. The azaleas are this season flowering far more lavishly than the Rhododendrons, and their yellow, orange, and flame-hued tones, add wonderful richness and variety to the scale of colour of the true Rhododendron. The hardy azaleas have received much attention, and many beautiful varieties have been raised at Highclere. Their effect, when seen mingling with the cooler hues of the Rhododendrons on the islands in the lake, is truly enchanting.

Art has done much for this lovely park scenery, but it must be admitted that nature had done very much before art began its work; for the natural undulations are exceedingly beautiful, and on a grand

scale : the Beacon Hill, which rises to close the view beyond the castle, being, at its upper ridge, more than a thousand feet above the level of the sea.

The finer and more carefully tended of the Rhododendrons and azaleas are those which form the great clumps of shrubbery that are picturesquely massed about the far-stretching lawns ; among which the intensely dark violet tone of the variety named after Sir Isaac Newton never fails to attract the eye, and the richness of the deep tones contrasts strikingly with the light pale pink of the Tree Peony, of which there are great clumps on the green sward, between the masses of Rhododendron.

Both on the lawn, and in the woods about the lake, there are scenes which, in the Rhododendron season, would have exercised an extraordinary fascination over the great painter, John Martin, whose intense love of colour could have found in them true models for those glimpses of the first Paradise, which are among the most successful of his imaginative pictures.

Not only do the rich masses of Rhododendrons and azaleas lead an artistic spectator to fancy they belong to some primeval paradise of flowers, but the noble cedars, of which magnificent trees there are so many at Highclere, complete the wonderful beauty of the scene so grandly, that the brush of the painter, in order to realise his favourite subject, would have need only to transfer to canvas precisely what he saw, without altering a single feature of the scene.

A visit to Highclere in the Rhododendron season is a delightful privilege not easily forgotten ; the only drawback being, that while there are so many other things to be seen, the gorgeous attraction of the azaleas and Rhododendrons occupies too exclusively the whole of the visitor's attention. There are, for instance, finer specimens than I have seen elsewhere both of *Abies Douglasii* and *A. cephalonica* ; the beautiful drooping growth of the one, and the healthy, robust habit of the other, being very remarkable ; but I had not a spare moment to bestow on them. The orchard house, too, in which Mr. Ross, the energetic gardener, has been so successful with abundant crops of peaches and nectarines by the judicious use of a little heat at a critical moment, and many other things of interest have to be passed over with scarcely a glance of appreciation. Even the castle itself, one of the best designs of the late Sir C. Barry, and the noble Vandyc's and Sir Joshua's in the principal apartments, can claim but a passing glance at this season, although one would desire to give a whole day to the pictures alone. There is an ancient yew, too, the trunk of which is nearly thirty feet in circumference, and which must have been standing, in its prime, on the spot where its ruin is now a noble wreck, when Roman and Saxon and Dane successively battled for the possession of these fair Hampshire hills. The church, which stood by the ancient yew, and which appears in the right of our illustration (for which we are indebted to "The Life of Sir Charles Barry"), is now in process of demolition, another church having been erected at a greater distance from the castle.

H. N. H.

LEVENS HALL GARDEN.

LOVERS of scenery are often narrow-minded, and, we have heard some sticklers for "nature" object to Chatsworth and its gardens as an offence against "the Derbyshire country." Still, every visitor to the Lakes who cares at all about the history of gardening ought to make a point of seeing Levens. The grey old mansion, with its tower and gables, its simple green terrace and long flight of steps up to the unornamented doorway, harmonizes perfectly with scenery—magnificent trees grouped about a wild mountain stream, and every here and there peeps of the background of fells, such as is seldom found except near the English lakes. Plenty of culture, plenty of richness ; those limes and sycamores, those avenues of oak and beech, and those huge pines and very tall birch trees, speak of solid peace at bottom ; while the brawling Kent and the bare scur of Whitbirrow take us back to the Moss-trooping days when, if safely out of the way itself, Levens was often called on to help less fortunate neighbours. The house, with its mixture of comfort and strength, tells the same tale as the grounds : You are on the edge of the Border-land, where every cultivator had his "peel," and was often glad enough to use it. Inside, the most noticeable feature is the perfection of the "keeping up ;" the rich oak panelling, the leather-work (in dining-room as well as bedroom walls), the tapestry, the plaster ceilings—all are trim and in order. How few old houses there are of which this can be said ! Look at South Wraxhall ; far the finest manor-house near Bath ; there is a historic place ; once much grander in every way than Levens, as fine as Haddon, which it much resembles, and (after having

been everything—even a boarding school !) it is empty, and fast falling to ruin. The wood-carving at Levens is very good ; the principal fireplace, with its "five senses, four seasons, and four elements," and—

"Samson supporting one side, as in rage ;"

"The other, Hercules, in like equipage," probably suggested to Coleridge those lines in "Christabel" about,—

"The chamber carved so curiously—
Carved with figures strange and sweet,
All made out of the carver's brain;"

just as his walk on Duddon sands taught him (he tell us) to say of the Ancient Mariner,—

"Thou art long, and lank, and brown,
As is the ribbed sea-sand."

But there is a similar Samson and Hercules fireplace at South Wraxhall (almost like the rest of the house) too far gone for preservation, while Levens is kept up, as such a place should be.

And the garden, with which we are chiefly concerned, looks as if it was still under the care of "M. Beaumont, Professor of the Topiary Art to James II.," who laid out Hampton Court gardens. It is even better than Elvaston, as a sample of what can be done with yew, and box, and holly. Here in the sheltered angle of the house are rows of pyramids with balls at top and bastionnettes fashioned in their angles ; peacocks, a poodle-dog wrought with Chinese fidelity, decanters, wine-glasses, foaming beer-jugs of yellow box, arbours impenetrable to sun or rain or peering eyes, tall mushrooms on slender stalks, a *judge's wig*, and other quaint devices. Use, too, is mingled with "ornament," all round the frames and hotbeds is an embattled wall, just so high that you can't tell what it conceals, and relieved with embrasures, &c. Among these yew and box trees are flower beds of most intricate patterns with wonderfully neat box edgings. Behind, dividing the main garden, is an alley of beech, with arches every here and there, and a central circular space beech-walled all round, which, if it had a few statues and vases, would speak even more than it does of Versailles and Wattcau. As it is, you look for the dent of high-heeled shoes in that soft, daisied turf, and for the rustling of hoops, and the glory of plum-coloured coats and laced waistcoats amid the tender green of the young beech leaves. It is all so exactly as it was, that, sitting in the rustic seat at the far end, you almost think you hear whisperings round the bowling-green, and a bough which has not yet put out leaf, does duty for a dress-sword projecting between the skirts of some perwigged beau.

It is not exactly the garden into which you would summon a romantically-minded young lady like Maud, though both the yew arbours and the high, thick green-walled beech alleys offer splendid flirting nooks ; but it is as good a sample as we know of what is wrongly called the Old French style, but which, of course, comes direct from the Romans, Pliny for one giving elaborate instructions as to how the *topiaris* is to improve on nature.

Such a garden is worth reproducing here and there ; it harmonises with a particular kind of house—better even with the Caroline style or the red brick of Anne, than with grey old Levens. Anyhow, it is worth seeing, especially when it has such an interesting house, and such a glorious park along with it.

And Levens is easy to get at ; it is five short miles from Kendal, down the Kent, which a little below it broadens out into a sandy estuary. You may walk to it in less than two miles either from Milnthorpe or Oxenholme stations, and in much less, if you happen to strike the "bit of a back loan," to which any passer-by will direct you. Either walk is, like all the walks thereabouts, lovely ; and whichever way you choose you must remember also to see Sizergh Castle, about a mile from Levens. This, the old place of the Stricklands, is a sad contrast to the other ; it is scarcely kept up at all, yet historically and otherwise, it is far the most interesting of the two. In its gardens are plenty of yews in a strangely intermediate state between trimness and wildness ; the *topiaris* has not been there for years. But the terraces and moat-garden are thoroughly English.

There are in the Lake country plenty of grand "places," besides the well-known Muncaster Castle ; but Levens and Sizergh, though not at all grand "places," are both well worth

seeing, just because they are thoroughly characteristic. They can be seen, too, without interfering more than to the extent of, say three hours with the tourist's programme.

Levens garden is something which few have seen, just because there are very few perfect samples of it remaining. M. Beaumont may feel consoled by its present trimness, for the banishment of his portrait from among those of the Howards and their peers to an out-of-the-way passage on the way to the kitchen.

F.

THE INDOOR GARDEN.

MARECHAL NIEL AS A GREENHOUSE CLIMBER.

I WONDER why it is one so seldom sees this rose used as a greenhouse or conservatory climber. Nothing looks handsomer when in flower or yields a more delicious perfume. It should be grown in a cool house; at least I have found it do well in such a situation. I have two plants of it, which I intend to train over the roof of a small span-roofed house. They are young, last season being their first for flowering, but during the summer I cut a very large number of blooms off them. This year they began to flower in February, and I have been cutting blooms off them ever since. At present they are covered with buds, and will keep on blooming until very late in the season. They are not in pots; I have them turned out into the ground under the stage, where I have a nice border made of proper materials to suit them, and I water them now and then with weak liquid manure. The stages in this house are flat all round, so I have the stems of the roses brought up through the stage and trained on the wires strained along the roof at a sufficient distance from the glass to prevent the frost affecting them. They require in the growing season to be well syringed, and if green fly makes its appearance, syringe them with a little tobacco or quassia water. They do much better turned out in the border than in pots, and they are not so subject to green fly. For a small cool house there is no creeper that so well repays one for the little trouble it may take in growing it as a Maréchal Niel rose; for what is more charming when in flower, or more useful for cutting for bouquets or button-holes?

A. H., Upper Norwood.

CULTURE OF CLERODENDRONS.

The different species of this noble genus bloom at various seasons; some during summer, others late in autumn. They are principally natives of warm climates, but fortunately, though most of them require a high temperature during the season of their growth, they will bloom from May until October in a warm greenhouse. Many imagine, probably from seeing large specimens at exhibitions, that these plants require a great deal of room; but several of the finest species, as *C. fallax* and its finer variety *superbum*, *squamatum*, *splendens*, and even *paniculatum*, may be bloomed with considerable success, in even six and eight inch pots, and if they are not started too early, will continue to enliven the greenhouse from June to November, or even later, if they are kept in a growing temperature; and at the latter season, their flowers come in very acceptable for bouquets.

In addition to species that have been introduced, some very beautiful varieties have been raised in this country. *C. fallax superbum* was, I believe, raised by the late Mr. Wm. Barnes. It is remarkable for producing, in addition to a fine terminal or central panicle of bloom, a number of smaller side panicles, varying in number from ten to thirty, which, under good management, generally furnish flowers from the pot upwards, forming a compact and beautiful specimen. Those who are about commencing the cultivation of Clerodendrons, will do best to procure the following kinds:—*C. fallax superbum*, *speciosissimum*, *paniculatum*, and *Kemperi*; to which, if they can be procured, may be added *C. fragrans* and its double variety, with the white *fortunatum*, and most certainly the trailing species, *C. splendens*, of which there are two varieties, one with much darker flowers than the other, and more profuse in its habit of blooming. Nor must on any account the lovely *C. Balfourii* be omitted. It also belongs to the trailing section, and bears clusters of white and scarlet flowers in such profusion as to make it a universal favourite. Supposing these kinds to have been procured, and that they are nice dwarf plants in small pots, we will make provision to commence their growth; and for this purpose a pit or frame must be prepared, in precisely the same manner that it would be made up for cucumbers or melons. Over the bed, after the frame is put on, place cinder ashes two or three inches thick; and as soon as these are warm, all will be ready to commence operations. Those who cultivate by the more fashionable method of hot

water will do well to take a hint from the preceding; for, after all has been said, there is no atmosphere in which all soft-wooded stove plants, and many of the hard-wooded ones also, will grow so well as in that produced by the decomposition of fermenting materials; and hence, if hot water for bottom heat is used, it will be advisable to take advantage of some well-prepared dung, to improve your atmosphere a little. In the opinion of some first-rate practitioners, and after trying all the various plans recommended, the perfection of heating, for vigorous and expeditious plant-growing, is a good system of hot water, combined with a well-managed dung lining.

All being in readiness, provide a compost of the following materials:—Three parts well-prepared fibrous turfy loam, one part turfy peat, one rotten cow-dung, with a handful of charcoal, broken to the size of horse beans, and sufficient white sand to keep the mixture free and open. Then take some eight-inch pots, and drain them with charcoal; turn the plants out of their pots; and if the roots are at all matted, open them out a little with a fine-pointed stick, and pot them into the prepared pots, using the compost as rough as possible, and be careful not to consolidate the soil too much; give them a little warm water, place them in the pit or frame, and draw some of the ashes round the bottoms of the pots, to give a little additional bottom-heat; but take care that the bottom-heat does not become too strong. Keep the frame at a temperature of 70° during the day, with plenty of air, and endeavour to keep a little air on also during the night, so that the heat does not fall below 60°. The plants will require shading for a few days during bright sunshine, and indeed it will not be a bad plan to throw a thin shade over every day for a few hours, as the leaves, being large, are liable to burn under an unclouded sun. Cold draughts must also be guarded against, as they too are liable to injure the tender foliage. In the management of the pit or frame, shut up early in the afternoon, so as to command a good growing temperature of 80° or 90°, but give a little air at the time of leaving for the night, so that the thermometer may fall to 60° or 65° before the following morning. Follow this treatment daily, taking care to secure sufficient head room for the plants in the frame, and keep a sharp watch upon red spider, which is very partial to these plants.

In a fortnight or three weeks from the first potting, they will require a second shift, at which time eleven-inch or larger pots may be used, draining them with oyster shells and lumps of charcoal, and using the compost as rough as possible. Return them to the pit, pursuing the same treatment as before, until the pots are again well stocked with roots, after which time it will be advisable to stimulate them a little by some liquid manure. The best way to prepare this, is to take two pecks of sheep or deer's dung, one peck of soot, and one-fourth of a peck of guano; place these in a large tub and mix them into a paste with ten or twelve gallons of boiling water, then fill the tub up with sixty or seventy gallons of rain-water, and stir the water repeatedly for several days; at the end of that time take the scum off and throw in three or four lumps of lime, and you will have a fine clean manure as clear as old ale. In using this, dilute it with half its quantity of clean water, and use it of the same temperature as the place the plants are growing in. This water is used for watering twice or thrice a week in clear weather.

Suppose the plants to have been procured in March, if they have made proper progress, they will be fit to shift into their looming pots by the middle or end of April, and of course the size of the pot for this final shift must be governed by the kind and size of the plants and convenience of house-room. I generally bloom one specimen in thirteen, fifteen, or eighteen inch pots, but I have had nice compact plants in eleven-inch, and even smaller, pots. After the plants show bloom, care must be taken that they sustain no check, or the panicle of flowers may be deformed or much checked in its progress, but if they are kept regularly and vigorously growing, a panicle upwards of two and a half feet long may be insured from *C. paniculatum*, and with its large and wide-spreading foliage I know no finer object. Remove the plants into the greenhouse as soon as they are fairly in bloom, and they will continue to flower until the end of the season. After the blooms begin to fade the plants must be gradually dried off, so that they may remain dry during the winter. In the spring cut them down to two or three eyes, remove the old soil, reduce the roots, repot into fresh compost, and start them as in the preceding spring. Clerodendrons may be propagated by cuttings of the old and young wood, planted in very sandy soil, and plunged in a brisk bottom heat of dung. They may also be increased by means of seed, which some of the kinds produce freely; it may be sown either in the autumn as soon as gathered, or any time during the spring months. *C. splendens* may be increased either by cuttings or by budding, or by grafting on the roots of the stronger-growing kinds. This and *C. Balfourii* require to be trained to a fancy trellis, or they may be planted out and trained up the rafter of the plant

stove, where they will produce a profusion of flowers for many months. These should not be cut in so close as the shrubby kinds. As Clerodendrons are plants which delight in a moist atmosphere, care must be taken to syringe them as frequently as possible during the time they are in a growing state. P.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Echinopsis Duvalii.—This charming garden hybrid has flowered beautifully this year in Mr. Peacock's collection at Hammersmith, under the skilful care of Mr. Crockett. It grows about ten inches in length and six inches in width at top, the colour being a delicate rose, the spines sharp and short, and the plant altogether does not exceed two feet in height. It is easily cultivated, and is certainly one of the best of the section to which it belongs.

A Neat and Inconspicuous Label for Pots—I saw in the houses of M. Demoulin of Mons, a useful label for all who object to conspicuous ones. It consisted of a piece of glass tube, one-sixth of an inch in diameter; the name or number was written on paper, rolled up so as to let the name appear, and put inside the tube. The ends were then sealed by a spirit lamp, so as to render the tube perfectly air-tight, and thus situated the name will last for ever, if the tube is not broken. Of course, larger tubes may be used when required.—J. CROUCHER.

The Pumpkin Passion Flower (*Passiflora macrocarpa*).—I have a plant of this which fails to fruit; it is growing in a large pot in a warm house. I shall be glad if you will tell me how to manage it.—JANE K. T.—[The plant may be grown in a moist warm stove, with the same facility as the granadilla; but it may be planted in a bed of rich, light earth, rather than in pot or tub, so as to permit the fruits attaining their full size. Probably, like the granadilla, it may require copious fertilization. Perhaps some of our readers, who have grown the plant, will kindly state their experiences as to its fruiting.]

Astilbe japonica.—This graceful hardy herbaceous plant, now everywhere becoming a favourite for forcing and for spring and early summer bloom in the conservatory, is usually imported for growing in pots. This is by no means necessary. By dividing old plants, and replanting them in April they will form good plants if planted on a fair sandy loam. They may be taken up and repotted in October, and forced or brought into bloom as circumstances may direct. This system is extensively pursued by Mr. Vertegans at Edgbaston, who finds the plants as good as imported ones.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 524.)

WHEN AND HOW TO WATER.

ONE of the first and most important rules in watering is this: When the plants are to be watered do it thoroughly, so that the soil may be fully penetrated. This will be known by the water running through into the saucer, which should be at least $1\frac{1}{2}$ inches broader than the bottom of the pot, to provide against an overflow into the room. As it often happens, when light soil is used, that from the dry air of the room some parts of the ball become so dry that the water will pass through into the saucer without wetting them, it is recommended that the water be allowed to stand for some hours in the saucer. This is the best method of securing the perfect penetration of the soil with water, and avoiding that dry condition of certain parts of the ball which proves the death of many plants. Whoever wishes to be careful of his plants will, after the lapse of from four to six hours, pour out the water which has flowed into the saucer. This is especially recommended to beginners, who, not knowing the proper time when to water, prefer giving too much rather than too little. But he, who from experience knows how not to water before the ball has become sufficiently dry to allow the air to percolate through it, need not pour out the water in the saucer, but will allow it to remain and be absorbed by the plant.

The assertion has often been made that the saucers which must be used in room culture are injurious, inasmuch as they produce a stagnant moisture. Others, on the contrary, advise not to water from above, but merely to fill the saucers. There is some truth on both sides. Where too much water is given, and the saucer is allowed to remain always full, it must be hurtful. But where water is given carefully the saucer is most useful, as we have just shown, in completing the moistening of the dry ball. This is the reason why beginners, who do not know the proper quantity of water to be given, find it advantageous to pour the water into the saucer, and allow it to be absorbed by the ball, the dry saucer indicating when water is again required by the plant.

The marks by which it may be known when the ball of a pot plant has become so dry as to require fresh watering, are

the colour of the soil, its feel to the touch, the weight of the pot, and the appearance of the foliage, &c., of the plant. Most kinds of soil when watered look much darker than when dry. There are some, however, whose nature it is to be dark when dry, and others to be light-coloured when wet. Of the former class are heath soil, leaf mould, &c. Of the latter, we may mention sandy soils, and those impregnated with oxide of iron. The various colours of the soils in a wet and a dry state must therefore be observed and borne in mind. The next way is that of feeling with the finger whether the soil is moist underneath; but this is a thing which requires considerable experience, the best way to acquire which is to have some dry earth at hand, by feeling which first, and then the ball of the plant, after some time the difference will be impressed on the sense of touch. An excellent plan is to compare the weight of the pot with another pot of the same size filled with soil which is known to be dry, or to strike the pot on the side with the knuckle; if dry, the sound will be very different from that of the same pot when wet. Lastly, the appearance of the plant affords a means of judging whether it is in want of water or not. When well supplied, its twigs and leaves present an aspect of fulness and stiffness; but, as the ball becomes dry and less able to supply the waste of evaporation, the foliage becomes relaxed and drooping, and if unrelieved, begins to dry and wither. In plants with soft tender leaves, when in full vegetation, this appearance is very striking; but, in those with thick leathery leaves it requires some experience to note the change. If the latter, on being bent together, present some resistance, it is a sign of dryness in the ball; but the extent must be learned by practice.

SOIL.

As regards the soil, the lighter and looser it is, the sooner does it become dry; and the stiffer it is, the longer it retains moisture. To this we may add that, the richer the soil is, the more cautiously should it be watered. It scarcely requires an explanation, that the looser the soil is, the more readily it parts with its moisture to the atmosphere. Loose soils are those which are largely mixed with sand or fully decayed vegetable matter. Light soils, as peat, leaf mould, &c., contain little mineral matter. Heavy soils are largely mixed with mineral substances, and without the admixture of sand are stiff. Rich soils are those composed of a mixture of animal excrement, or of decayed vegetable matter, and stiff soil. In soil suitably rich, a plant makes a strong, stout growth, with thick rather than long branches, and with firm leaves, and exhales only a moderate amount of moisture. In poor, loose soils, the plants produce thinner branches and more tender leaves, which exhale a large quantity of moisture; and when grown in a room in dry air present a drooping appearance, even when the dryness of the ball is far from being as great as that of a plant growing in good rich soil. This is because the former were accustomed to take up a much greater quantity of water for sustenance, and so, in dry hot weather, exhibit signs of dryness before it has actually set in. As an illustration, we may state that we have seen gardens in which a loose, poor soil was used in the culture of all the New Holland plants, and where large specimens were grown, in small pots. In hot, dry weather, these were watered morning and evening, and yet during the day the young shoots often hung faded; whereas if a strong mixture of loamy soil had been employed, a single daily watering would have been sufficient in the hottest weather to prevent any such signs of dryness. Whoever has made a long journey on foot in hot weather, will have made similar observations with regard to himself, to those we are now making on plants. The more one drinks at such a time, the more he perspires and the greater grows his thirst.

The pots and their sizes also exercise a very great influence on the dryness of the soil, and their construction must be especially attended to in room culture, where an ornamental shape is considered a requisite. The qualities of a proper flower-pot are,—a means of thorough drainage, porosity of the sides in the greatest degree that such solid material will allow, and, lastly, such a shape as will permit the ball to be taken out without injury.—Dr. Regel.

(To be continued.)

GARDEN DESIGN.

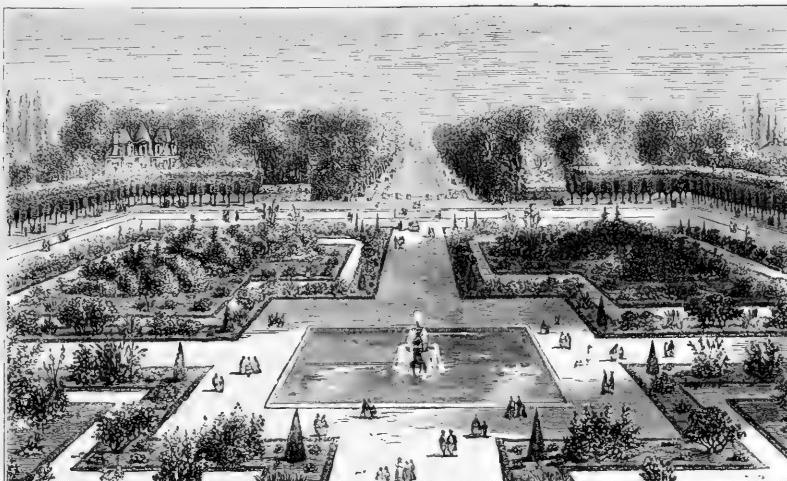

GEOMETRICAL FLOWER GARDENS.

FONTAINEBLEAU.

WHENEVER the geometric principle is resorted to in the planning of flower gardens, the design should be a work of art, in the true sense of the term. The leading lines should be so boldly conceived as to render the intention of the designer strikingly intelligible at the first glance. It is quite as difficult a matter to devise a geometric garden really worthy of the name, as it is to imagine and carry out, with *unseen* art, the irregular curves of a garden landscape. In a geometric garden, the plan should be so self-evident as to enable the eye to grasp the intended effects very quickly, while a certain amount of intricacy is at the same time necessarily required as an evidence of care and of skill in the creation of the device. This intricacy must not be obtained by means of obscurity of plan, nor by means of infinitesimal divisions of parts, nor by endless varyings of unmeaning forms. The spotty, patchwork effect produced by

to be unworthy of notice, unless for the purpose of critical condemnation. At the same time, I have had the good fortune to meet with one or two brilliant exceptions, which do the highest credit to the architectural designers.

Among the most successful of the celebrated geometric gardens designed by the great French masters of the art, the flower garden attached to the Palace of Fontainebleau is one of the most successful. It will be seen by our illustration that the character and intention of the device are, as they ought to be, plainly obvious, and the forms made use of can be appreciated at the first glance. A square basin, in the centre of which are seen the moving waters of a handsome fountain, forms the keynote of the design, and it should be carefully noted that the square form, as a centre, gives much nerve and crispness to the entire composition, necessitating as it does the well defined forms of the beds which surround it. The simplicity of these divisions is enriched by the reduplication of the lines, by means of an enclosing border, which is separated from the bed it surrounds by a narrow walk. The quadruple repetition of this device produces a remarkably fine and pleasing effect, and the outlying borders which flank it, to the right and left, serve to bind it together and give completeness and cohesion

Geometrical Flower Gardens at Fontainebleau.

the last-named kind of helpless struggle to produce an elaborate design for a geometric garden being, of all the unfortunate mistakes usually committed, the most vulgar and the most objectionable.

It is not sufficiently taken into consideration that the designing of a fine geometric garden is a work requiring much thought and much artistic knowledge. Is it, in fact, as difficult as the designing of the facade of an important mansion or palace; and it is well known that the best examples are undoubtedly those produced by great French and Italian artists, who were at once architects, sculptors, and the designers of the framework of garden scenery by which their architectural elevations were to be surrounded. The art education required for the successful performance of the work in question is now almost entirely ignored; any person, even when entirely untutored in art, being deemed fully competent to undertake the planning of a so-called geometric flower garden. Even among our architects, few would be found able to furnish a decent design, so entirely has that branch of the architectural profession been neglected at the present day. I have myself recently seen two specimens of geometric gardens devised by architects, which are so utterly ridiculous and childish as

to the general composition, which combines simplicity with intricacy in an extremely felicitous manner.

Even the cropped limes, seen from a central point in this geometrical garden, are not unpleasing in aspect, though a shrubby enclosure in which the action of the shears had been confined to much less conspicuous operations would certainly, according to the highest canons of modern horticultural criticism, have been much more acceptable. On the whole, however, and taking for granted that a geometrically-planned garden may, in certain circumstances, be an admissible, and even a desirable, feature in immediate proximity to a country mansion, it must be admitted that the Fontainebleau design is a very successful one. There is, also, an extraneous feature in close connection with it, which greatly adds to its pleasing effect, by allowing the eye to escape from the rigorous geometrical forms along the far-stretching vista of an avenue of limes or elms. Deprived of that outlet, the effect would be something like that of a painted landscape filling up the whole canvas, without a peep of sky, and without the streak of indefinite blue distance, which, while it is always charming in itself, imparts additional attraction to the strongly-de ned features of the foreground.

H. N. H.

THE ARBORETUM.

THE PLANES.

BY GEORGE GORDON, A.L.S.

V.—THE WEDGE-LEAVED PLANE (*PLATANUS CUNEATA*—WILLDENOW).

THIS forms a stunted low tree or bush, with a short stem and tortuous branches, somewhat ascending. It is seldom seen above twelve or fifteen feet in height, and often retains its leaves half the winter. It is a native of the Levant, and was first introduced in 1739.

The leaves are palmately wedge-shaped and smaller than those of any of the Planes, being seldom more than four inches and a half in length and three and a half inches broad. They, however, vary very much, both in size and shape, according to circumstances. Those on young and vigorous plants are deeply divided into five open lobes, the principal ones of which are more or less wavy, and sometimes furnished with a pair of small lateral blunt lobelets, and a few frequently hardly evident serratures, terminated by hard points, while on old

Leaf of the Wedge-leaved Plane.—Natural size, 4½ inches long, including footstalk, and 3½ inches broad.

or stunted plants the leaves are very much smaller and frequently but three lobed, with the lobes more or less angular, not much divided, and furnished on the edges with a few small teeth. All the leaves, however, of this Plane taper very much to the base, and in some cases, so much so, as to leave but a very short footstalk. Like those of other Planes they are quite glabrous in the adult state, but densely coated all over with a woolly substance when quite young. It has not yet produced balls or seed-heads in England, nor have they been described by any botanist.

This Plane is sometimes called *Platanus undulata*, and is considered by most writers, as only a stunted variety of *P. orientalis*. Be that as it may, however, it is a very distinct kind.

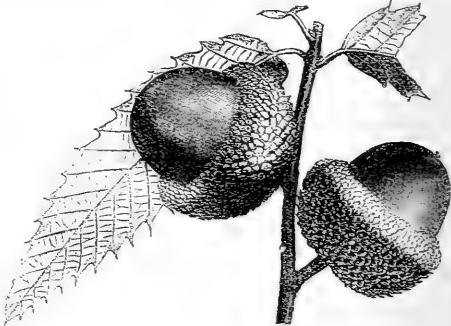

OAK OF LEBANON (*QUERCUS LIBANI*).

In the accompanying figure we have given an illustration of the fruit and leaf of the species which M. Carrère considers to be the "type" of the Lebanon Oaks, and which he thus describes in the *Revue Horticole*:

"A vigorous tapering tree of handsome appearance, with spreading and distantly-set branches; the bark of the smaller branches of a

brownish grey colour, and covered with a slight pubescence. Leaves deciduous, comparatively distant, leathery, of a lively glistening green on the upper surface, from three to nearly five inches long (including the stalk, which is yellowish and about half an inch long) from one inch to nearly one and a half inches broad, the limb being a little larger on one side at the base, which is concave, and then rounded; the margin of the leaf is dentate with distant, stiff spine-like teeth. The male flowers are disposed in very small, few, and slender catkins, and appear in April, when the fruits (now in their second year) are about the size of green peas. The female flowers (which bear the acorns) make their appearance in summer, a long time after the male flowers have disappeared, and are solitary, or more frequently in pairs, on thick and woody stalks about quarter of an inch long. The cup covers about one-half of the acorn, and is surrounded by numerous fringed and imbricated scales, the upper ones being smaller and closer together, and forming a well marked prominence round the top of the cup. The acorns are from one and a quarter inches to one and a half inches long, and somewhat less in diameter, broadly truncate at the base, and abruptly rounded at the apex, where there is a very short blunt point. The hilum is broad and bears some very small point-like prominences."

"In the climate of Paris the fruit ripens from the 1st to the 15th of October, and is of a dark, nearly black, chestnut colour. As this

Oak of Lebanon Acorns.

species varies as much when raised from seed as almost all our European species, it will be necessary in order to have it true to name, to graft it upon stocks of the common kinds. It thrives well in warm and light calcareous clays."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Old Yew Tree.—About fourteen years ago I saw in Gresford Churchyard, near Wrexham, a remarkably fine Yew tree, the dimensions of which I took, but I have since lost them; perhaps some reader of THE GARDEN in that neighbourhood will furnish us with its present size, which I do not think will quite equal the one mentioned by Mr. Berry at page 436, but which is nevertheless well worth recording; I, who have been an observer of trees all my life, have never seen a yew tree in all respects so fine.—J. E.

Cedar of Lebanon Killed by Frost.—A remarkable occurrence took place during the severe frosts of the month of September last. A large Cedar of Lebanon, of more than two yards in circumference, on the property of M. Doisant, at Villepinte, Canton de Gonnesse, in the department of the Seine et Oise, was completely killed by frost. At how many degrees below zero the thermometer stood to produce such an effect has not been stated. That which is certainly past all doubt is, that the cold must have been excessive—greater perhaps than in the different places where so many thousand evergreens have been destroyed about Paris.—*Revue Horticole*.

Salix babylonica Salamoni.—This is a tree of extraordinary vigour, acquiring large dimensions, which renders it advantageous for burning, particularly in bakehouses. It can also be recommended for its ornamental character. It is well adapted for an avenue; and possesses the advantage of thriving in nearly any kind of soil, and accommodates itself perfectly to calcareous and dry soils. As an isolated tree it recommends itself particularly for the beauty of its bearing, its abundant branches, and the thickness of its foliage. Another quality of which we must speak is the length of time this willow retains its leaves, which greatly increases its ornamental merit; whereas the greater number of trees which have frail leaves, are stripped in September or October, those of the S. b. *Salamoni*, only fall after the frosts commence.—E. Carrère, in "*Revue Horticole*."

GARDENING FOR JUNE.

THE INDOOR GARDEN.

BY T. BAINES, SOUTHIGATE.

Conservatory.—Where conservatories are attached to the mansion, the destruction of aphides and other insects is always a difficulty; fumigation is always objectionable, inasmuch as it not only leaves for days an unpleasant smell in the conservatories, but also communicates it to the adjoining apartments. A good deal, however, may be done to obviate the necessity for using tobacco smoke; closely examine, for example, all plants before introducing them, and never by any means admit any infected plant until it has been subjected to a thorough cleansing. Nevertheless, this in itself will not suffice, as clean plants are just as liable to become infected in conservatories as elsewhere. The best remedy, therefore, for such matters is the old, somewhat neglected application of tobacco water. It is well always to keep a few gallons of this ready for use, and as soon as a plant is discovered affected, to at once remove it, and give it a thorough washing before it communicates the evil to all around it; by this means it is possible to reduce the necessity for fumigation to a minimum, and thereby avoid its disagreeable consequence. Plants permanently put out in borders, or others in pots for permanent decoration, frequently become exhausted; in such a case when not convenient to repot or change the soil, liquid manure is generally given, and is often applied; this is as objectionable on account of the bad odours it gives off, as the means usually employed in the destruction of insects. This, in a great measure, may be neutralized by a liberal admixture of powdered charcoal and soot with the liquid for a week before it is used, keeping it well stirred up for a few days, and then allowing it to settle, so as to employ it in a clarified state. Keep a good look-out for red spider on roof-climbers, a favourite resort for it, and one where it gives a great deal of trouble, by infecting every plant placed under it on which that pest will live. A thorough washing with the garden engine early in the morning once or twice a week as a preventive, will be found good practice. During this and the next two months there is generally a paucity of flowering plants. The most should therefore be made of such as are available, by paying them all possible attention, never allowing them to suffer from want of water. In very hot weather every plant should be looked over twice a day. *Lilium auratum* and *L. eximium* should be largely grown for decoration at this season. The former is objectionable in large quantities at a time on account of its overpowerful smell; but in moderate numbers it is indispensable, and by a little foresight in selecting such as show a tendency to late flowering, and placing them in a position to favour this habit, their blooming season may be much prolonged. This Lily will be found to associate well with foliage plants, that may with advantage now be introduced into conservatories, such as *Theophrasta imparialis*, *Rhopalanthus*, *Dracunculus*, and ferns that have matured their early growth. If a portion of the earliest flowered *Fuchsiae* were, towards the end of the month, turned out of doors for a fortnight, kept a little short of water, so as to harden them, and then cut back and repotted into pots two or three inches larger than those they have occupied, and removed to a house or pit where they can be liberally treated, they will amply repay for the labour, as they will break out afresh, and bloom freely until autumn. Plants of *Bougainvillea glabra*, growing in the stove, may now be removed to the conservatory, where they will form striking objects for six or eight weeks, if placed where they will not be suddenly checked by draughts, in which case they are liable to throw off their blooms. By the middle of the month, plants of *Ixora coccinea* may be placed in the warmest and most sheltered end of the conservatory, where they will stand good for six weeks without injury, provided they are kept as dry at the root as is safe without endangering the health of the foliage. When it is necessary to give water, let it be applied in a tepid state.

Stove.—Look well to forwarding all plants that will be required for autumn and winter flowering. *Euphorbias*, *Poinsettias*, *Aphelandras*, *Justicias*, and *Gesneras*, should never be allowed to suffer for want of potting on; the best practice with all such things is to get them on to the size they are required as early in the season as can be done, so that they may have the benefit of being well matured before the days get short. Plants that are so managed and get in such condition as to stand a comparatively cool airy house during August and September, will flower much more satisfactorily than such as are kept growing on late in the season. Whatever shade is required during this month—and some things will require it, if the weather becomes seasonably bright—should always be drawn down sufficiently early in the day to prevent scorching. Span-roofed stoves that stand north and south require shading on the sunny side much earlier than those that are built

the opposite way; but on no account allow plants to remain shaded later in the day than is absolutely required. All insect pests that affect stove plants will now thrive apace; and unless continually sought for and destroyed, they soon multiply to such an extent as to destroy that healthy, vigorous appearance which constitutes the principal charm of a well-managed plant stove. *Dipladenias* will now be fast coming into flower and should be well attended to in order to encourage them to keep on through the season; this cannot be done unless they are liberally supplied with manure water. *Stephanotis floribunda* is a universal favourite, and is indispensable at this season for cut flowers. Plants grown in pots, if run up to the roof of the stove, ought to be trained in such a manner that they can be wound round a trellis, and the plants removed to a cooler temperature where their flowers will keep fresh much longer than if allowed to remain in the stove. Gardenias that have done flowering, if as large as required, should be cut back and placed in a growing temperature; when they have pushed fresh growth, they should have a portion of their old soil removed, and be repotted in the same sized pots as those they came out of, using good peat with plenty of sand in it; as they are fond of water, it is essential that the soil should be of such a character as to let the water pass freely through it.

Fern House.—Any scarce varieties which it may be desirable to increase from spores, should have their fertile fronds closely watched to see that they do not get too old, before the spores are placed under conditions favourable to their germination. The pots that are to receive them may be filled with two-thirds drainage, over which use two or three inches of fine sifted peat, liberally mixed with bits of charcoal, broken sandstone and silver sand; give the whole a good soaking with water so as to solidify the surface; otherwise the spores will be washed too deep to germinate. Sow them thickly on the surface of the soil, do not cover with anything, but give a gentle watering with a fine rose, and never allow the soil to become dry. Plants suspended in baskets, or those like *Platycerium grande* that may be on blocks, ought to be well attended with water, or they never do well. Attend to such plants as are grown specially for cutting during the winter months, particularly *Adiantum cuneatum*. These are best grown in six-inch pots, and not kept too warm; when they have made as much growth as is required, let them be removed to a cool house, where they will not be excited to make late growth, but gradually hardened off. With such treatment they will stand much longer than if kept growing on in a close temperature.

Orchids.—*Cattleyas*, *Dendrobiums*, or any plants that were not potted when the general stock was gone through, on account of their being advanced in bloom, should be potted as soon as they have flowered, before they begin to make active growth, otherwise if their roots are in full activity they will suffer. If the winter flowering *Calanthes* are growing fast give them sufficient room. To keep their leaves short and robust, give them also plenty of light, but keep them from the direct action of the sun's rays, otherwise they will suffer. These plants do best in an ordinary stove, or in a muscat house, where a fair amount of fire heat is used, and more air given than in the confined atmosphere of the orchid houses. The East Indian plants now will require their maximum amount of heat and moisture, viz., from 65° to 70° night temperature, with from 75° to 85° during the day-time with sun heat, giving sufficient air to dry up the house moderately; closing early with a moist atmosphere, and never allowing the blinds down for an hour longer than is absolutely necessary. *Odontoglossums*, and similar plants, should if possible, be accommodated with a house that can be kept comparatively cool, with a thoroughly moist atmosphere, and plenty of water at the roots; never on any account subject them to drying currents of air.

Hard-wooded Plants.—Those in active growth will now require close attention in regard to water, even such as are most impatient of any excess will now require more than at any other season. In very bright weather keep plenty of water thrown about the house and under the stages, to counteract in some measure the drying effect of the sun. Place such sun-loving plants as *Aphelaxis*, *Phenacomias*, and *Epacries* at one end of the house, these, unless after fresh potting, will be benefited by full exposure to the shining sun. Such plants as *Boronias*, *Acrophyllums*, *Hedera-mosas*, *Dracophyllums*, and *Roellas*, will be benefited in very bright weather by being placed where they could be slightly shaded for two or three hours during the hottest part of the day. Remove all flowers and seed-pods as soon as they become unsightly. Young plants attend closely to, and examine them towards the end of the month, to see if any are likely to require more root-room before autumn. Any that are likely to require it should be repotted towards the end of the month, unless the weather happens to be very hot and dry, in which case it will be better to wait a short time for duller weather. Heaths encourage to make all necessary growth, &c that

they can be got out of doors to ripen their wood well before too late in the autumn. In this respect they will be much assisted by plenty of water around their pots, under the stages, floors, &c., but they must not on account be subject to anything approaching a close atmosphere. Stop the shoots of such as are too vigorous.

THE FLOWER GARDEN FOR JUNE.

BY GEORGE WESTLAND, WITLEY COURT.

THE unusual inclemency of the weather during May and a low ground temperature have considerably retarded the operation of bedding-out half-hardy plants; and we would particularly impress upon cultivators of sub-tropical plants the necessity of having them well hardened-off prior to planting out, for upon this they must in a great measure depend for immediate effect, as any sudden check at this stage often mars their appearance for the season. As a rule, therefore, we would defer planting out until the second or third week in June, or, at all events, until such time as the ground shall have become sufficiently warmed to promote active growth.

As regards the disposition of plants in the flower garden, the selection of kinds suitable for particular positions as respects associations and surroundings, is of paramount importance. Much as we may cherish sub-tropical plants and others of picturesque aspect, these are not admissible in geometrical and other formal designs, where perfect proportions and symmetry must be strictly adhered to.

The larger foliated plants are better disposed in isolated beds, upon grass, or as single specimens, where they give a fresh charm and relief to the more formal system of beds. With the exception of Cannas, few of them are adapted to dense grouping. Indeed, they are far more effective when so disposed that each plant clearly exhibits its proportions, and an appropriate groundwork of low plants lightens up and sets off their graceful outlines to advantage.

In preparing beds for such plants as Alternantheras, Coleus, Iresines, &c., it is important that the soil is free; and, where fresh peat is an object, we have found nothing to answer better than the refuse from under the potting-bench, passed through an inch mesh riddle, adding leaf soil or rotten dung as required, to insure richness. In planting Alternantheras, more particularly amena, which is somewhat delicate, but by far the highest coloured, it is necessary to plant sufficiently thick, to give immediate effect.

Watering will soon become an important operation; but be it remembered that if the plants are properly secured in the ground, the surface frequently stirred and pulverised, and afterwards mulched, they are seldom benefited by watering during their present stage of growth, especially as the ground temperature is so low and the nights so cold. Water, therefore, only when absolutely necessary. And so long as the nights are cold, this operation should be done early in the afternoon. Recently-planted trees and shrubs must be well attended to; if they require watering it should be done thoroughly; and after the surface has become partially dried, remove an inch or two of the soil over the roots; apply a mulching, and cover this with the soil, so as to give to the whole a neat appearance, and save watering and labour hereafter. Unremitting attention should now be paid to the training of climbers, so as to prevent their becoming entangled, and to the staking of everything that may require support. Proceed, too, with the pegging down of all plants that may require that attention as they advance in growth, and make good any failures that may occur. Make successive sowings of some of the choicest hardy annuals for autumn sowing, and thin out such as may require it; bearing in mind that annuals when properly thinned out and cared for are far more effective than if left to flower without being regulated. Brompton and intermediate stocks should now be sown, as should also seeds of the variegated Winter Cress (*Barbara vulgaris variegata*), upon a shaded border. It is one of the most striking plants for spring bedding which we possess. Take advantage of showery weather to plant out annuals. Top-dress Carnation and Pink beds with rotten dung, to which has been added a dash of fresh loam. Hoe and otherwise keep in check weeds upon walks and borders. Clip grass edgings, and everywhere maintain a neat, cheerful appearance.

Pits and Frames.—These will now be at liberty, as the majority of plants reared in them will have been turned out. They may, therefore, be useful for such things as Capsicums, Cucumbers, Tomatoes, &c., and for the rearing of young greenhouse stock, as well as for the propagation of choice biennials and perennials. Cineraria seed sow for late flowering, and plant out old stools cut over upon a shaded border in rich soil to induce offsets. Primulas, such as were sown and pricked off early, may now be potted off into small pots, and placed in a shaded situation near the glass. Propagate show Pelargoniums by cuttings; and continue to pot off and stake tender annuals to be grown in pots.

THE FRUIT GARDEN FOR JUNE.

BY WILLIAM TILLERY, WELBECK.

Outdoor Fruits.—This has been a most disastrous season as far as tender vegetables and fruits are concerned, for in this district on the mornings of the 19th and 20th ultimo, the thermometer registered 4° and 6° of frost respectively. This has given the finishing touch to the young fruit of Gooseberries, Currants, and Raspberries, for all on the tops of the bushes, and unprotected by the foliage, are destroyed. All the earliest flowers of Strawberries are likewise quite black in the centre, and of course the germ of the fruit is injured. So much for mild, wet winters, and cold, frosty springs; and it will generally be found that weather in season is always best for our hardy fruits and vegetables. During these last few days there has been a rise in the barometer, and a higher temperature, and the chances are that we may have a dry warm June to put vegetation in a somewhat better position. Where Pears and Apples have set too thickly, thinning the fruit will well repay for the operation, as the specimens will be individually finer, and the tree will have a better chance of bearing well year after year. The stopping, thinning, and regulating the young shoots of all kinds of fruit trees on walls, will now want attention. The foresight shoots on Plums, Peaches, Apricots, and Cherries, should be shortened back, and the other shoots nailed or tied in as they advance in growth; great attention will now be required in keeping down insects, for if grubs and aphides are not taken in time they will do much injury this month to the foliage. To add to the misfortunes inflicted by frost on Gooseberry bushes, I see that the caterpillar has commenced its ravages on the foliage, but I find that a dusting of powdered white hellebore on the shoots infected, generally clears them. Thinning out the strong shoots from the interior of Gooseberry and Currant bushes should now be done. The black aphid often infests cherry shoots, especially the Morello, and the best way to keep it in check is to pinch the ends of the shoots off, and then syringe the trees with tobacco water. All kinds of fruit trees on walls, after the shoots have been thinned and regulated, will be much benefited by a good syringing from the garden engine, to cleanse them from insects and abortive fruits. Suckers and spray from the roots and base of Nut and Filbert bushes will now want removing. There was a great paucity of catkins on Filbert bushes this year, and I am afraid that the crop will be scanty in general. On some rows of young bushes I placed branches of wild Nuts from the woods, with catkins on them, which have fertilized the Filberts, and I expect a fair crop, if grubs keep off.

Vineries.—Houses containing ripe fruit will now want keeping dry, with abundance of air in fine weather. Continue to thin the berries at timely periods, to keep laterals stopped, and to avoid over-cropping. In the very latest houses, the Grapes intended for bottling when they are ripe, should be well thinned, so as to get fine, large, well-swelled berries; and as Lady Downe's Seedling generally forms a shoulder as large as the main bunch, it ought to be clipped off, as the bunch will keep longer and plumper without it. Young Vines planted in spring will now want every encouragement; water them with liquid manure in dry warm weather, and stop them once or twice on their journey to the top of the rafters, so as to get strong and well-ripened wood and fine foliage. Young Vines growing in pots, and intended for fruiting early next year, should likewise be stopped once or twice, and, if possible, the wood should be well-ripened off by the end of July, when they may be placed out of doors to mature the wood till pruning time.

Peach House.—When the fruit begins to ripen, a drier atmosphere must be maintained, with plenty of air; and if some is left on at night, the flavour of the fruit will be much improved, as well as its colour. Attention to stopping and tying down the shoots in succession houses, and syringing once or twice a day to keep the foliage healthy and clear from insects, will now be the routine for June. In thinning the fruit of Peaches and Nectarines grown on trellises, that facing the sun should be left, so as to be of the finest colour when it gets ripe.

Figs.—When the first crop is all gathered, the trees must be well watered at the roots to encourage a second crop, and the foliage should be syringed daily to keep down red spider.

Cucumbers.—A steady bottom heat will still be required from linings of hot dung, to Cucumber plants grown in frames. Fumigate with tobacco if thrips or green fly make their appearance, and it is good practice to repeat this operation two or three times after the lapse of a week or two, in order to eradicate these pests. I find that the *ne plus ultra* of Cucumber growing, where great quantities are required, is to grow them in a pit heated with hot water. A pit of this kind here has furnished a supply of from twenty to thirty brace per week for the last three months, and it is yet in full bearing.

Some of the best known varieties have been grown and proved in this pit this year, but one known here as 'Holah's Seedling,' has taken the lead of all the sorts for productiveness in the winter and early spring months. It is, I believe, a cross between Telegraph and Sion House; it is of a useful size, fine shape, and would suit market gardeners well for their winter supply for market.

Melons.—The earliest planted out in pits or houses will now be ripening fruit, and a drier atmosphere and less water to the roots will be required, to secure flavour. When the fruit is all cut, a second crop may be successfully secured by watering the borders well with tepid water, and cutting the plants down to some healthy young shoots. If the plants are grown in frames, a bottom heat of from 65° to 70° must be maintained, and mats still used as coverings at night in cold weather. Thrips and red spider are more difficult to keep down in plants grown in frames than in pits, on account of the undersides of the foliage not being reached by the syringe. Fumigations and moist air must therefore be resorted to should they appear, and a little water dashed frequently on the leaves; if it is mixed with soot and soft soap it will be all the more effectual.

Strawberries.—The last batches of Strawberries for forcing will now want bringing in, and if their fruit has been set in pits or frames they will now ripen in succession without much forcing, until the outdoor fruits come in. In the midland districts the outdoor Strawberries in flower have been much injured by frost, and the crops will be later in ripening in consequence.

THE PINERY FOR JUNE.

BY JAMES BARNES.

The season has now arrived when many of the early summer fruiting Pines have attained maturity, and some of the most forward have been cut. When a clearance has been made by the removal of those plants that have yielded their produce, in order to obtain well-swelled, handsome, and finely-flavoured fruit, no time should be lost in clearing out the pits, washing, repairing, and painting the lights, and also thoroughly washing and painting the walls. For the last operation should be used a mixture of fresh lime slackened with boiling water, sulphur vivum or black sulphur, and as much fresh chimney soot as will give the whole a dark greyish colour. This is a splendid mixture for sweetening and cleaning all foul walls both indoors and out. Remove some of the old worn-out fermenting material and replace it with fresh material sweet and healthy, incorporating all well together by turning the whole mass two or three times. No time should then be lost in plunging in this renewed bed the earliest and most forward of the early autumn and winter fruiting plants. Maintain a high and steady temperature; give air night and day, being guided by discretion and the state of the weather; apply kindly waterings to the roots of liquid manure, and keep up a strong humid atmosphere in the case of all swelling fruits. Attend to previous directions as regards approaching maturity and beginning to colour.

Succession plants in all stages must, according to their necessities, be shifted, and supplied with more growing room. Keep them near the glass, let them have the full summer heat, atmospheric humidity, frequent applications of tepid manure water, and syringings from the engines or otherwise early in the afternoon. Remove all suckers as they appear, repot without delay, and place them in front of the succession plants. Syringe the growing plants once or twice a week with clear tepid soot water.

THE KITCHEN GARDEN FOR JUNE.

BY JAMES BARNES.

Asparagus.—Desist entirely cutting from young plantations after the first week of this month, and cut only moderately from old established ones, till about midsummer, when cutting should be entirely suspended. Apply a little salt frequently to the surfaces of the beds; evenings of dull, cloudy, or, preferably, rainy weather, are the best times for this operation. Apply salt also in dry, bright weather, only to kill weeds, which it will readily do, and nothing is better for clearing weeds from walks, and keeping them clean and of a good colour. When the Asparagus-cutting season is over, and the shoots are allowed to grow, cut off the weak ones, and allow only the robust and strong ones to grow, which will strengthen the crown buds for next year's produce. For seed, only the strongest, best coloured, and earliest "grass" should be selected, and securely staked. Never save the seed by hap-hazard, as no improvement would then be obtained; by careless culture a tendency to degenerate is also induced. Maintain a clean and healthy surface by constant hoeing and scarifying the ground. It is too often observed, especially in the case of seedling-beds, that as soon as the plants come up and

cover the surface, weeds are allowed to grow and luxuriate amongst them, and they prove exceedingly pernicious to the plants, which consequently become weak and spindly. It is much better to thin the plants, and keep the ground open and particularly clean, for then we obtain strong healthy plants, instead of the miserable, starved subjects that would otherwise be produced.

Beet.—Keep clean, thin moderately and methodically, but not too much, for large, overgrown roots are never sought for; moderate size and fine colour should be aimed at. Fill up gaps by transplanting. **Burnet and Borage.**—Make another sowing; make vacancies good in rows, by transplanting while young. **Cardoons.**—Thin and fill up vacancies; also encourage their growth by occasional applications of manure water. Keep a sharp look-out for mildew amongst seed-beds, &c., and apply dressings of dry wood-ashes on dewy or damp evenings, or the surface may be damped with a watering-pot or syringe. **Borecole, and other Kales.**—Plant out a full crop as also Broccoli, Brussels Sprouts, Savoys, and Cauliflowers. Of the last mark a few first-class flower-heads for seed. Prick out in succession all small plants. **Beans.**—Of late garden varieties, where they are in request, still plant a few on cold, stiff land, as long as they can be produced, timely pinching out the tops of those just coming into bloom. French and Runner Beans.—Plant liberally throughout this month, and keep free-growing kinds pretty often stopped. **Coleworts.**—Sow twice or three times this month. The London Green and Atkin's Matchless are nice, small, and compact kinds; the small York and Nonpareil are also good varieties for autumn and early winter use. **Cauliflowers.**—Sow freely, both early and late kinds, about the middle of the month, for autumn and winter use. **Capsicums and Chilies.**—Plant out on warm borders; give those intended to remain in pots under glass the last shift; they should take the place now occupied by forced strawberries.

Celery.—Continue to plant out in succession established plants in their permanent quarters, and prick out young plants in narrow lines. Keep a clear, open surface soil, and never allow a check in growth for lack of water; and keep the growing plants free from suckers. **Chervil, Chicory, Corn salad, and Cress** sow in succession. **Sow American Cress** for the next six weeks under north walls or in shady aspects for autumn and winter use. **Cucumber** ridges keep clean, mulch and peg out the vines uniformly, and methodically stop their points. **Endive**, both curled and new Batavian, sow twice this month, always thinly, to obtain short, healthy plants; and continue to plant out in succession, between celery or in rows a foot apart each way on borders or quarters. Tie or cover with tiles or slate such plants as are fit, on dry afternoons, to bleach ready for use.

Lettuce.—Sow in succession, thinly in drills. Thin out if the weather is dry; if moist and cloudy, the plants can be drawn for transplanting. Of Parsley sow another full crop; also Radishes in variety, on cold situations or north borders. **Rampion** sow fully for autumn use. **Spinach** sow often, and encourage the growth of the New Zealand variety for summer use. **Peas.**—Continue through this month to sow late varieties in succession. **Turnips.**—Make small but frequent sowings of the small, quick-growing kinds, such as the American Stone, Snowball, Dutch, Early Strap, Red Globe, &c., in succession. **Vegetable Marrows.**—Mulch, train, stop, and peg down a portion of their shoots in order to prevent wind from driving them about. **Herbs.**—Make the last sowing out of doors of Sweet Basil and Marjoram; plant out full crops of well hardened-off plants on well-prepared borders or quarters. **Leeks.**—Plant out in rows two feet apart, and a foot between the plants in the row, or in trenches deep enough to afford sufficient earth being applied for blanching. **Seakale.**—Do not forget to remove all spurious and weak shoots, leaving only two or three strong crowns to each root; keep clean, and apply dredgings of salt in showery weather. Keep an open, loose surface amongst all growing crops, never allowing a weed a chance of putting in an appearance; and thus prevent yourself being robbed of the best produce. Apply, moderately, sprinklings of air-slacked lime to all rows of Peas and French Beans, and seedlings of all kinds at an early stage.

THE ARBORETUM FOR JUNE.

BY JAMES BARNES.

See that newly-planted trees and shrubs have their stakes and ties all right. Upright-growing trees should have all contending leaders removed, leaving only one; balance all dwarf-growing trees and shrubs by stopping back wild-growing, luxuriant shoots. Maintain a clean surface amongst all new plantations, and encourage a rapid, healthy growth, till the trees are able to take care of themselves. Prick off into small pots all young, choice conifers, as soon as they can be well handled. Place the pots in shallow frames or pits, and

shade moderately until they begin freely to form fresh roots. If the stock is too numerous for placing in pots, shallow turf or wooden pits (or even those formed by placing a tier of bricks two or three deep around, so as to afford a little shelter and shade if necessary) should be prepared, and filled with some kindly preparation, into which the seedlings should be pricked from three to four inches apart. Mildew sometimes proves very destructive to young conifers, and nothing is better as a preventive than a dressing of dry wood-ashes when the plants are a little damp. Besides being the best eradicator of this disease, wood-ashes are always safe to use, and are a powerful fertilizer. They should be stored, when quite dry, in boxes or tubs, and placed under cover to keep them dry. There is always a great deal of refuse about an estate fit for no other purpose than ash-making or charring, and, considering the great value of such material as a manure and deodorizer, it is of immense importance.

MARKET GARDENING.

BY H. EVERSHED.

THE quantity of vegetables eaten by all classes of society was largely increased during the last century, and a greater and more general advance in this direction has been made by the present and the last generations. The actual increase of population has also enlarged the demand for vegetables, and hence a new branch of agricultural industry has been created. Fuller shows us the beginnings of market gardening two hundred years ago; he wrote in 1662, "Since gardening hath crept out of Holland to Sandwich, in Kent, and thence into this county (Surrey), where though they have given six pounds an acre and upwards, they have made their rent, lived comfortably, and set many people on work." In the same Thames-side district, lying between Battersea and Kew, this Flemish industry still flourishes on the light soil that suits it, and the Flemish implement of tillage or its substitute, the American fork, is used in cultivating the gardens. But it is only articles of limited consumption, such as cauliflowers, radishes, asparagus, forced vegetables, &c., that are produced on this original site. The more common and necessary vegetables are consumed in such enormous quantities that more space, as well as implements of more power, are needed for their production. London, too, has encroached on the former scene of spade-labour, and the old market gardens of Surrey have been devoted to a large extent to other purposes. East and west of London the soil is of very similar character, consisting of light land on gravel, equally suitable for vegetables; but in the east the subsoil is without veins of clay, and the district, therefore, is without fruit trees. The extension of garden farming in Essex, with horse tillage and steam cultivation, in one instance, has been rapid. A wealthy grower of vegetables is only lately deceased who was among the first to emigrate from the older site in Bedfordshire. He arrived in the new colony without capital, and without the skill to read or write a market-tally, and lived to occupy a farm where more than five hundred acres of vegetables were grown every year.

THE ESSEX DISTRICT.

The Essex district extends from Stratford, bricks and mortar permitting, to West Ham, and thence through East Ham, to Barking, Rainham, Dagenham, Hornchurch, and Romford. The parishes of Aveley and Purfleet are at present, but may not long be, beyond the boundary of vegetable growing. They are now famous for early peas, and on June 19th last year large gangs of women were picking the first crop. At Rainham strawberries were begun on the same day, and potato digging had commenced a few days earlier. The crops are all seven or eight days earlier than they would be under ordinary farming, without the warm coat of manure. The subsoil of the Thames Valley is a drift of sharp small flint, or gravel; it is generally covered with good light loam, which is in many cases several feet in depth, and is continually enriched by heavy dressings of dung. This light soil being peculiarly absorbent of air, heat, and moisture, and admitting of the rapid decomposition of organic matter, is naturally suitable for vegetables, and produces good crops of corn when, after a heavy green crop, it is not in too high condition. Elms are the native timber trees of the district, growing in rows to a great height with leafy trunks, trimmed to resemble monstrous specimens of Jersey cabbage-stems or Brussels sprouts, with a cabbage on the top. Near Rainham, however, there are several noble avenues of unmitigated trees, which ornament as well as shelter the country. The water-level is generally at from four feet to ten feet from the surface. This district takes most of the manure produced in the eastern part of London, and it supplies a large portion of the fresh, bulky vegetables consumed in the metropolis between spring and autumn. The whole of the produce is sent by road, and

except near a river wharf, or close to a station, the manure is brought by the waggons on their return from market. The outlay on the farms, as will presently be shown, generally exceeds £20 an acre, and requires such a return as is yielded only by garden crops and garden-farming. The growth of corn has been almost abandoned. In this district of large garden farms the fields are seldom less than ten acres in extent, and are generally from twenty to forty acres.

In garden farming there are no strict rules with regard to the succession of crops; the land is kept constantly under crop by sowing, or by replanting from seed-beds as fast as the fields are cleared. Cabbages may follow cabbages; and the loading of the market-wagon [proceeds in one part of the field while the plough-teams and planters are busily employed close by. On ordinary farms the necessity for a regular distribution of the labour of the farm throughout each period of the year, and for alternating the crops which produce manure with those which expend it, renders a tolerably regular rotation of crops desirable; but, as garden farms employ five or six times as much labour in proportion to their acreage, their reserve force is larger. Moreover, they are generally situated in the neighbourhood of large floating populations, and extra hands and extra horses, at certain seasons of the year, can easily be obtained. The rest is accomplished by the purchase of dung. An approach to a systematic rotation arises from the necessity of keeping delicate subjects—such as onions and potatoes—at a distance of several years apart. Having already given examples of such successions, a few remarks on double crops, and the periods of planting and removing them, will suffice for what can be done in reference to economy of time and ground.

In the London district potatoes are followed by a second crop. The earliest may be followed by cabbages, the later by savoys, and the latest by "collards," for bunching during the winter months, when cabbages are out of season. Cabbages should not be planted much later than the third week in June; they will then be sent to market in November. Savoys are next pricked out from the seed-bed; and collards, which are planted almost at any time when there is a piece of ground to spare, follow up to the end of August. On the 29th June and 6th July last I was in fields where digging potatoes, manuring the land, ploughing, and planting cabbages, collards, and mangold, were proceeding without any delay. It was a little late for cabbages, but the frequent showers would, it was believed, enable the plants to start at once and rapidly. The land was dunged well and ploughed once with two horses, and the furrow was tender and crumbling. In dry seasons the transplanted crops require watering; and although irrigation generally is neglected, it is sometimes very beneficial to garden crops. A fifty-acre gardener, who grows celery, cauliflowers, and other crops, showed me a little rivulet running through his ground. It costs him £60 a year; but, "when other grounds are scorched," he said, "my garden is as green as a leek!" Last year I am afraid he had to "eat the leek" in consequence of the general abundance. It will give some idea of speed in gardens if I mention that cabbages planted in the second week in April afforded a first cutting last year on the 28th June. Another example of double crops is in the case of early cabbages, which are sent to market in April and May. A month before cutting them, the land being in good tilth, holes are made in the rows with a spade, one hole between each cabbage; a boy follows and plants potatoes, which are covered with the earth taken from the next row. This plan obviates the treading which occurs when the sets are planted between the rows.

On the 19th June a large farm was shown to me where all the cabbages had been marketed, and a considerable breadth was in potatoes, planted in the manner described, and looking well. The cabbages had been planted two feet apart, and the potatoes were of course at the same distance. They were Regents, to be followed by some spring-sown crop. Other examples of two and even three crops in a year occur in the gardens near London, where certain vegetables of limited consumption are produced under spade cultivation, when there is no room for a plough. Peculiar virtues have been attributed to the spade as an instrument of cultivation, but the secret of the great fertility which follows the spade lies in the heavy dressings usually applied to the gardens. As an example of this kind of cultivation, I visited a large garden of forty or fifty acres, in the parish of Bermondsey, flourishing in the midst of smoke and vile smells. The larger part of the garden is planted with radishes, cauliflowers, and celery, taken from the same ground every year; and the rotation is repeated every year, with the precaution of moving the site of the rows of celery. These are planted five feet apart, with two rows of cauliflowers between them. The ground is dug in the ordinary way, once a year, in winter, as soon as the celery is removed. One hundred tons of dung per acre are sometimes applied, at a cost of between £30 and £40. The radishes are sown in March; the cauliflowers having been sown in October in frames, and protected

from frost during the winter, are pricked out among the radishes; and the celery follows. Eight acres of rhubarb are cultivated with the fine five steel fork. I was told "the more manure the more rhubarb." Asparagus is forced by frames and hot dung. Plants of three years' growth afford three weeks' cutting, and are then destroyed; and a less price than 7s. 6d. for a bundle of 105 does not pay the grower.

On the 11th July a large bed was planted with collards and Waller's broccoli in alternate rows, at eighteen inches from row to row. The broccoli will be sent to market in November. There is a large fenced plot for cucumbers and vegetable marrows. The very deep cultivation which is frequently heard of, and occasionally practised in agriculture with more or less profit, has not been found desirable in market gardens. The cabbages, greens, cauliflowers, broccoli, onions, potatoes, cucumbers, &c., which fill the markets of London, are generally grown on a seven or eight inch furrow; and, as a rule, only one furrow is turned for each crop. In the case of subsoiling for late carrots and for parsnips, the object appears to be to give mechanical assistance to the root, to enable it to run down long and tapering. One of the most eminent growers of parsnips in the metropolitan district cultivates nine or ten inches deep by means of a common plough, followed by a subsoil plough. A six or seven inch furrow is enough for two horses, and three or four inches are as far as the subsoiler reaches in a gravel loam with three horses. Trenching, double-digging, bringing the bottom spit uppermost, and all those tricks of tillage described in gardening books, are repudiated by market gardeners, who do not pay much attention to the "mine of wealth" which does not exist in gravel subsoils; they seem to think that the sources of wealth lie in the dungcart, and in the judicious management of the upper spit.—*Royal Agricultural Society's Journal.*

(To be continued.)

THE HOUSEHOLD.

THE TRUE ST. GEORGE'S MUSHROOM.

(*Agaricus gambosus*.)

The St. George's mushroom cannot well be mistaken for any other. The fact of its appearance in spring, and growing so freely in rings, when so very few other funguses are to be found, is almost enough to distinguish it. It has, however,

St. George's Mushroom (*Agaricus gambosus*). Pastures, in the spring; colour, cream; diameter, 4 to 6 inches.

very distinctive characters in itself in the thickness of its pileus; the narrowness of its gills, which are very closely crowded together; and the solid bulging stem. The St. George's mushroom is not an uncommon agaric in this country, and where it does appear it is usually plentiful—a single ring affording generally a good basketful. It should be gathered when young, or it will be found grub-eaten, for no fungus is more speedily and more voraciously attacked by insects than this one. It grows in rings, has a strong smell, and appears about St. George's Day (April 23rd), after the rains, which usually fall about the third week in April. It continues to appear for three or four weeks, according to the peculiarities

of the season. It is usually to be found on hilly pastures in woodland districts.

Pileus thick and fleshy, convex at first, often lobed, becoming undulated and irregular, expanding unequally; the margin more or less involute, and at first flocculose; from three to four inches across; of a light yellow colour in the centre, fading to almost opaque white at the edges; it is soft to the touch; more or less tuberculated, and often presenting cracks. Gills yellowish-white, watery, narrow, emarginate, i.e. annexed to the stem with a little tooth (see section in illustration): they are very numerous and irregular, with many smaller ones interposed, "lying over each other like the plait's of a frill" says Vitelladini. Stem firm, solid and white, swelling at the base in young specimens; but in older ones, though usually bulging they are specimens of even size, and when in long grass they occasionally even taper downwards. This agaric is usually nearly white, smooth, soft, and firm, like kid leather to the touch, and, as Berkeley has happily said, "in appearance it very closely resembles a cracknel biscuit."

Opinions on the Merits of Agaricus gambosus as an Edible Fungus.

"This rare and most delicious agaric, the *mouceron* of Bulliard, and the *Agaricus prunulus* of other authors, abounds on the hills above the valley of Stafora, near Bobbio, where it is called *Spinaroli*, and is in great request; the country people eat it fresh in a variety of ways, or they dry and sell it at from twelve to sixteen francs a pound."—*Letter from Professor Balbi to Persoon.*

"The most savoury fungus with which I am acquainted . . . and which is justly considered over almost the whole Continent of Europe as the *ne plus ultra* of culinary friandise."

"The *prunulus* (*gambosus*) is much prized in the Roman market, where it easily fetches, when fresh, thirty baiochi—i.e., fifteen pence per pound—a large sum for any luxury in Rome. It is sent in little baskets as presents to patrons, fees to medical men, and bribes to Roman lawyers."—*Dr. Badham.*

The *Agaricus gambosus* "is one that a person cannot well make any mistake about. It sometimes attains a large size, is excellent in flavour, and particularly wholesome."—*Rev. M. J. Berkeley.*

Mode of Cooking Agaricus gambosus.

"The best mode of cooking *Agaricus gambosus* is either to mince or fricassee it with any sort of meat, or in a *vol-au-vent*, the flavour of which it greatly improves; or simply prepared with salt, pepper, and a small piece of bacon, lard, or butter, to prevent burning, it constitutes of itself an excellent dish."—*Dr. Badham.*

"Served with white sauce, it is a capital appendage to roast veal."—*Edwin Lees.* It may be broiled, stewed, or baked.

Breakfast Agaric.—Place some fresh-made toast, nicely divided, on a dish, and put the agarics upon it; pepper, salt, and put a small piece of butter on each; then pour on each one a tea-spoonful of milk or cream, and add a single clove to the whole dish. Place a bell-glass, or inverted basin, over the whole; bake twenty minutes, and serve up without removing the glass until it comes to the table, so as to preserve the heat and the aroma, which, on lifting the cover will be diffused through the room. It dries very readily when divided into pieces, and retains most of its excellence. A few pieces added to soups, gravies, or made-dishes, give a delicious flavour.

THE "WHY" IN VEGETABLE COOKERY.

Why should haricot beans never be put into cold water to soak, as is often recommended?—Because all the nutritious portion of the bean is extracted by the process. They should be washed in warm water, then in cold, be tied loosely in a cloth, be put into boiling water with a spoonful of dripping and a little salt in it, and be kept boiling for four hours. They are then excellent if served with gravy, and not with melted butter. They serve as garnish round roast mutton or beef, and are excellent eating served whole or as a *puree*. To make the latter, when the beans are done throw them instantly into cold water, when the skins will slip off. Rub the beans through a colander, and mix a lump of butter with them. A little stock, or milk, or cream is excellent mixed in.

When the flavour of vegetables, as celery-seed, carrots and turnips, is required, why should they be put into cold and not into boiling

water?—For the reason that if put into boiling water the whole flavour is retained in the vegetables, but if in cold water it is drawn out into the water, and is thus suitable for soups. The latter has a better flavour if the vegetables are put into it when it is boiling, and are served with the soup. Of course this will only do for excellent family soups.

Why should plenty of fast-boiling water be used in boiling vegetables, potatoes excepted? Because the greater the body of boiling water the greater the heat. If only a little water be used the whole affair soon cools, and the vegetables become tough, so much so that no length of time in boiling them will render them otherwise. Broccoli sprouts in April, if properly cooked, by boiling them for eight minutes in boiling water, will be tender as marrow; but if not properly done, hours will not cool them.

Why should onions be always cut in round and very thin rings?—Because the fibre is thus cut across, and in so cutting them, whether for frying or for making sauce, they are rendered very tender when cooked. Turnips and carrots just the same; neither of the three should be split or cut in any other way.

Why should parsley never be boiled with soda, only in boiling water and salt?—Because parsley, having no oil in it, would be spoiled with soda, and all flavour would be extracted. All parsley should be picked free from the stem, be put into plenty of boiling water with salt, and in summer be boiled only one minute, in winter two minutes, be then strained and chopped on the back of a plate. If only a little water is used in boiling it, the latter becomes brown and the parsley tough and ill-flavoured.

Why should vinegar for pickling with never be boiled?—Because boiling takes all strength from it. Whatever vegetables are to be pickled should first be made soft with boiling water, strong with salt, then be well drained, and the vinegar poured over.

Why should two ounces of salt and a bit of washing soda always be put in the water to boil greens in?—Because the salt crisps the greens and flavours them, and the soda extracts the oil, which is greatly injurious to the digestion.—*Treasury of Literature*.

COVENT GARDEN MARKET.—May 31st.

Flowers.—Amongst white blossoms for bouquet-making, Stephanotis is most abundant, so much so, that fully half of the nosegays consist of it. Gardenias, Tea and other Roses, especially buds of the Moss kinds, Pinks, and blue Centaureas, play prominent parts in such compositions. Plants in pots consist chiefly of Golden-rayed Lily, of which there are many nicely-bloomed plants; young Hydrangeas, with single stems crowded with unusually large heads of bloom; and Calceolarias, both beautifully-marked herbaceous kinds and common bedding yellow sorts; amongst the last we have noticed no dark-colored bloomed ones for some time. Besides these there are various kinds of Heaths, Cacti, both white and red flowered; Gloxinias, in baskets and pots; Balsams in flower, and younger plants of the same, not yet in flower, in the boxes into which they have been pricked out; Petunias, both single and double; pots of Mignonette and Musk, some in full bloom, and others only advancing to that state; and single and double zonal and other Pelargoniums. In addition to plants in flower, there are various kinds remarkable for the beauty of their foliage, such as nice graceful young Pandanuses, Palms, Marantas, Begonias, Caladiums, Dracenas, &c.; also many young plants in pots for outdoor decoration. These last consist of six-inch pots containing seedling Tropeolums, Convolvulus, Sweet Peas, and Nasturtiums. There are likewise many seedling annuals, raised both in pots and boxes, and also several climbing and trailing plants.

SOCIETIES, EXHIBITIONS, &c.

MR. WM. PAUL'S ROSE SHOW AT THE CRYSTAL PALACE.

THIS exhibition, which closes to-day, has been open since the 24th ultimo. It is nicely arranged, and, on the whole, very effective. In order to break up and relieve in some measure so striking a band of brilliant colour, variegated Maples, golden-leaved Oaks, and several kinds of green and variegated Iries, are introduced among the Roses, as are here and there, baskets of Golden Feverfew, variegated Thyme, and stands of cut blooms. Besides Roses, there is also a large collection of Zonal Pelargoniums, some of which are grafted on clean stems, a foot or more in height. Among Roses, the finest seems to be Duke of Edinburgh, a hybrid perpetual kind, with large double dark-red blooms. In the same class are also some good examples of François Fontaine, Dr. Andre, Paul Verdier, Pierre Notting, Madame Charles Wood, and Maréchal Vaillant. Amongst Tea-scented kinds President, Rubens, Alba Rosea, Monsieur Furtado, Madame Celina Noirey, and Madame Villermoz, are conspicuous.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 3.
Royal Horticultural Society, Regent's Park.—Exhibition of American Plants, up to 15th instant, 9 a.m. to 9 p.m.

Coventry and Warwick Floral and Horticultural Society.—Exhibition of Flowers and Fruit, Coventry.

Entomological Society.—Meeting, 9 p.m.

TUESDAY, JUNE 4.
Zoological Society, 9 p.m.

WEDNESDAY, JUNE 5.
Royal Botanic Society.—Promenade.

Royal Horticultural Society.—Great summer show (three days).

Leeds Horticultural Society.—Show in Royal Park.

THURSDAY, JUNE 6.
Royal Horticultural Society of Ireland.—Second spring exhibition.

Linnean Society.—Meeting.

FRIDAY, JUNE 7.
Royal Botanic Society.—Lecture in museum, 4 p.m.

SATURDAY, JUNE 8.
Royal Botanic Society.—Meeting for election of new Fellows and general business, 3. 45 p.m.

OBITUARY.

MR. G. W. HOYLE died somewhat suddenly at his residence at Reading on Sunday last, aged 71. For many years Mr. Hoyle has been a most successful raiser of seedling pelargoniums, and to him we are indebted for many of our best named show varieties. Few exhibitions have taken place in Regent's Park during the last quarter of a century at which he has not been present, anxiously scrutinising either his own flowers or those of his rival breeders, Foster and Beck. His seedlings were to him not only a source of profit, but pleasure, and he was never weary in pointing out their merits, and even, now and then, their defects, to all who took an interest in such matters.

DR. WIGST, Grizeley Lodge, Reading, also died on the same day, aged 71. His name will be remembered in connection with cotton-growing in India, a subject to which he paid much attention while in the East India Company's service in that country.

ANSWERS TO CORRESPONDENTS.

K. LEPPIN (M. W. THOMAS, Liverpool).—F. D. N. (continued).—WT (very beautiful; we will inquire).—Erxia (fumigating with tobacco, or smoke)—F. M. (a form of *Polenomium carolinum*).—A. B. W. (Asters, various, white, pink, or blue; *Tritoma Urviria*, red and orange; *Chrysanthemums*, yellow, white, or red; *Pyrethrum uliginosum*, white; *Hibiscus moscheutos*, pink; *Liatris spicata*, purplish; *Amenone japonica*, white; A. J. H. (Hornbeam) (all of the above are perennials, and all late-flowering perennials). Many of the well-known annuals, if sown in June or July, will also be found to answer your purpose).—R. H. (Very good indeed, the leaf markings are distinct and striking. The fanciers of tricoloured Pelargoniums might take exception to the somewhat serrated leaf edges).—R. (The common *Stellaria graminea*).

The Name and Address of the writer are required with every communication, though not for publication, unless desired. Letters or inquiries from anonymous correspondents will not be inserted.

All questions on Horticultural matters sent to THE GARDEN will be answered by the best authorities in every department. Correspondents, in sending queries or communications of any kind, are requested to write on one side of the paper only.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same address.

Readers who may find it difficult to procure THE GARDEN regularly through the newsagents, may have the numbers sent direct from the office, at 10s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained. THE GARDEN can be had in neatly covered monthly parts. On sale at Messrs. Smith & Son's bookstalls, and may be had through all booksellers. Part VI., for May, now ready, price 1s. 5d.

GARDEN

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

THE GARDENS OF ENGLAND.

BENTHALL HALL, NEAR BROSELEY.

A BEAUTIFUL old house (date 1535), the gardens embellished with many of the hardy plants common in England at the time of its erection, and with many, too, first brought across the sea by its owner, Mr. George Maw, within the past few years. There are, or were, but few private gardens in the British Isles resembling those at Benthall. The late Mr. Borrer's wonderful botanic garden at Henfield, and Mr. Wilson Saunders's full and varied collection at Reigate, may be compared to it; Mr. Maw's garden being, however, far richer than any of them in interesting and valuable hardy novelties. Indeed, for the culture and introduction of valuable new and hardy plants—the most legitimate object of a public or private botanical garden—there is not a more noteworthy garden. I have never seen a place in which the charms of association were more agreeably woven round the plants. Here is a houseclock from the Atlas, a sedum from the Sierra Nevada, rock roses from Gibraltar, an iris from Tangiers, and a primrose from the Alps, all collected, brought home in a living state, and successfully grown by Mr. Maw. And so all over the garden, every step bringing some fair or interesting distant part of the earth before us for the moment in the person of one of the earth children. Not a day but brings fresh and interesting plants into bloom, scarcely a week passes without some fair European or North African flower first opening its eyes in British air. The chief feature of the garden is a very extensive collection of herbaceous and alpine plants. Many of the families are more than usually well represented, particularly as regards new members and authentic species, and none more so than

THE SAXIFRAGES, STONECROPS, AND HOUSELEAKS.

I had the happiness of seeing some good collections of Saxifrages, but none on the whole so satisfactory as this. There was the well known one of Mr. Borrer, at Henfield, who had about seventy varieties of the mossy or *Hypnoides* section; the excellent collection of Mr. Niveu, in the Hull Botanic Garden; the Kew, and some good ones in the nurseries round London; the well-grown ones in the Jardin des Plantes at Paris, and also that of good old M. Boreau, of the Botanic Gardens at Angers, who has made a study of the family; but, on the whole, this Benthall collection is the best by far, for several reasons. It contains many new species, named and unnamed, mostly collected by Mr. Maw, and some of these of the highest value as garden ornaments. It is as complete as any other in the species long known in our gardens. All the kinds are grown to perfection in the open air. This last is a great point. There never was a greater mistake than that of growing these hardy and vigorous, though small, mountain plants in pots. They require it no more than a collection of willows. Silvery, Irish, or mossy sections, they all grow to perfection in the open air, in any kind of soil. Here they grow in a long bed, very slightly raised towards the centre, the soil being well mixed with small lumps of broken sandstone. Even this, however, though beneficial, is not necessary for the majority of kinds. The capital plan of placing a little sand over the surface, where such dwarf kinds as *Saxifraga cespitosa* and *S. valdensis* grow, is carried out with a good result. *S. cespitosa*, which is so often seen like a stain on the Alpine rocks, is here now snowy with its delicate blossoms. At the time of my visit there were eighty species in flower of this interesting family—the most important of all to

cultivators of alpine plants; and of these the finest was the sturdy *S. Mawiana*, discovered by Mr. Maw himself, in North Africa, and named in his honour by Mr. Baker. This, like most of the saxifrages from the same country, seems to completely perish in summer, after flowering and seeding, but again comes up abundantly from the little bulbils left at the base. It has a remarkably firm, compact habit, and bears myriads of large, waxy, white flowers, and deserves a place in every rock-garden. *S. Wilkomeana* is another remarkable kind, collected by Mr. Maw, and which, while showy in flower, is peculiarly marked by its very large, massive leaves, which form broad flakes of the richest green. It will prove an admirable rock plant. Other kinds are equally interesting; but of these we must reserve notice for the present.

The Stonecrops (Sedums) are equally well done, and also rich in novelties, about seventy species being cultivated. These, also, are all grown in the open air, and treated like the saxifrages. Among these was noticeable an as yet unnamed kind, like our common, brilliant, yellow stonecrop, but twice the size, and otherwise distinct. Of the Houseleeks (*Sempervivums*) there is a collection of about fifty species, treated in like manner.

POT CULTURE OF ALPINE PLANTS.

Here I met with one of the first attempts to cultivate alpine plants in a worthy manner. We are all familiar with the wretched examples of these plants that are sent to our shows even by famed growers. Seldom could one gather from a specimen of one of their collections that alpine plants were specially distinguished by spreading out into the most vivid cushions of vivid colour; seldom the faintest notion of what their true habit or beauty is. Here there is every evidence of the highest cultural skill being applied to them. They (mostly true alpine or rock plants, and not herbaceous ones) are grown in shallow cold frames in pots of a peculiar size—eight inches broad by four inches deep. These seem peculiarly well suited to the wants of alpine plants, securing, as they do, a good body of soil not so liable to rapid changes as that in a small vessel; while in stature, being only four inches high, they are exactly what is wanted for these dwarf plants. The common garden pan suits some alpine plants well; but is not so well suited to the stature of alpine plants, or the wants of their roots as this. The principle of culture adopted as a rule is the best we know of yet, that of annually dividing and replanting; placing the young plants, suckers, or divisions as the case may be, equally over the surface of the pot. Treated thus, they soon furnish it.

RAMONDA PYRENAICA AS A POT PLANT.

This handsome alpine plant, so seldom seen in vigorous condition, is rarely suspected to be capable of forming as handsome a specimen as any of the cyclamens that now appear so often at our shows. It is usually seen at its best with two or three sprays of flower in our botanic gardens and good private collections. Here, in a window of the dining-room, I had the pleasure of seeing a specimen nearly a foot in diameter, and with quite a little cloud of its large soft mauve flowers. The plant had been grown in a cool frame all through the winter and spring; at Benthall, however, it does well in the open pat border. It thrives in any rich free loam. The largest pot specimens at Benthall were formed by putting a number of young suckers in a pot. So I presume we may in due time look for it at our early summer flower shows.

ARRANGEMENT, &c.

Some of the more important families, as for example the very fine collection of Saxifrages (considerably over one hundred in number), are grouped together in one long bed; much as the same family is by Mr. Verlot, in the Garden of Plants at Paris. But in a good many cases a desirable change is made in grouping in the same bed or mass, two widely different families; as, for example, Lilies and Pansies, or Golden Rods and Grasses. This is an improvement on the common plan of grouping single families together in the same ground, inasmuch as the effect is better, the soil less exhausted, and the plants in no danger of being confounded or mistaken by those who have to attend to them. There is a capital system of labelling with terra-cotta labels, capable of application to all kinds of plants. This, originated by Mr. Maw, is now in use in many gardens.

In addition to naming the plants in the ordinary way, a second series of labels is used, which renders good service in the rare, or new plant department. To plants, the seeds of which are to be saved, a black label (unwritten) is placed. A blue label marks those which are to be increased by cuttings, taken up in the autumn, or otherwise treated so as to secure their preservation through the winter, while a yellow one indicates those of which specimens are to be dried. This system simplifies and improves the work of preserving and keeping in proper order such a fine collection.

NEW PLANTS.

While enjoying in his own way the highest pleasures of which gardening is capable of imparting, Mr. Maw confers at the same time very great benefit on our gardens by the introduction of very many valuable and ornamental plants. Some of these have been figured in the leading botanical periodicals, as, for example, the showy *Cotyledon Salzmanni*, the very curious *Drosophyllum lusitanicum*, *Linaria tristis*, *Malope malacoides*, *Salvia interrupta*, a handsome hardy species, the fine variety of *Audrosace carnea* known as *eximia*, the pretty *Sedum glandulosum*, the brilliant *Iris* or *Xiphion filifolium*, *Saxifraga Mawiana*, and the superb *Iris tingitana*. There are besides many unnamed species in the garden, and every prospect that, while so much has been done to enrich our collections within the past three years, much more may be expected in the future.

Among other novelties in the garden may be noticed some dwarf and brilliantly coloured Pyrethrums from the Atlas as yet unnamed; the brilliant Pyrethrum sulphureum from Spain, nine inches high; Papaver speciatum, a fine orange red species; the Etna Barberly, the only European species besides the common one; Phalangium beticum, a new, hardy plant in the way of the St. Bruno's Lily; Medicago suffruticosa, a fine rock plant from the Pyrenees, a spreading mass of gay yellow blossoms; Euphorbia verrucosa, large tufts of golden green throughout the summer; Linum salsoloides, a new and valuable perennial flax; Linaria villosa, a gem for the rock-garden; Nepeta latifolia, an ornamental species; Mentha humilis, cultivated in the south of France; Cerinthe alpina, the only introduced perennial kind; Antirrhinum sempervirens, a fine rock snapdragon; Salvia taraxacifolia, lately flowered by Mr. Niven, of Hull; Narcissus gaditanus; a gem of a daffodil in the way of *N. juncifolius*; Lathyrus monspeliensis, an everlasting pea related to the common one. There are many other novelties, which will be duly described in THE GARDEN from time to time.

W. R.

THE FLOWER GARDEN.

THE ROSE GARDEN FOR JUNE.

BY GEORGE PAUL.

A WEEK'S bright weather has brought out pruned-back Roses in profusion, though by no means improved by the past inclement spring. Truly, this has been a difficult season for the grower; let him, therefore, lose no time now in trying to repair injuries received. All plants should be at once carefully gone through. Remove the majority of shoots on which the flowers have been destroyed, and let all the sap go to cherish any buds that remain. Remove, in most cases, all but the central flower of each truss, the single bloom has room then to develop its full beauty; the practice has been condemned, but is perfectly defensible on the ground that individual flowers are improved by it; and one fine Rose is worth half-a-dozen poor ones.

Pegged-down roses have shown the value of this method of growing the queen of flowers in a bad season; of early kinds the eyes that started at the end of the pegged-down shoots were crippled and destroyed. The buds next in order down the stem shot out and gave a fresh uninjured lot of flowers, to be succeeded by the large and late terminal flowers on the shoots which burst from the base to furnish next year's supply of flowering wood, to be bent down in its turn. Caterpillar pests will have done their worst; but they should still be looked for and crushed mercilessly. The ground is quite moist still, and until the buds have swollen, where deep hoeing has kept up a mulch of loose soil, no further dressing or manure, liquid or solid, is just now needful, i.e., on heavy soils; gravels and sands can hardly be too closely watched, a week's drought telling more than three weeks dry weather with us on rose soils, i.e., good stiff loam.

In about a fortnight or a month's time we may expect heat, and

then, as Mr. Reynolds Hole has so ably described, all hands must be put on to the barrowing of the carefully-prepared mulch (liquid manure, saturated horse droppings, or thick liquid cow manure, applied on two or three occasions), if possible just before a drenching storm.

Exhibitors should get their boxes painted and varnished, tubes in order, and other minutiae in readiness for action. Pot Roses past their best, keep cool and ripened off; they no longer require exciting stimulants. The directions given last month for those still opening their flowers should be followed; but by the end of May all indoor Roses in pots should be over.

HARDY PLANTS IN FLOWER ROUND LONDON.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Gardens in Devon and Cornwall.—I am about to spend a month in North Devon and South Cornwall. Can any of your readers tell me of any botanical or other gardens open to the public, to be found there? Murray and other guides are silent on the point.—J. R. D.

Pelegonium "Mrs. P. J. Perry."—I find this variety to be the best of the white margined variegated race. The white is purer in tone than any other variety I have raised, and I strongly recommend it to your flower-garden readers.—V.

The Peacock Anemone.—With me this species proves very disappointing. After a year's cultivation on so it appears to degenerate from the beauty of the Constance type, the sepals assuming a greenish character, which renders the plant scarcely worthy of a place.—J. R. D.

Erinus alpinus as a Wall Plant.—I was pleased the other day to find this lovely little spurge luxuriating on an old wall in the Fulham Nursery, where its small flowers were produced in such profusion, as to form quite a sheet of red bloom on the face of the wall for a space of some yards. In this position the plant forms neat little tufts, and is a true perennial, whereas, on the level ground it mostly perishes in winter from excess of moisture or other causes.—T. S.

THE CHINESE RICE-PAPER PLANT.

(ARALIA PAPYRIFERA.)

THIS, though native of the hot island of Formosa, flourishes vigorously with us in the summer months, and is one of the most valuable flower-garden ornaments we have. It is handsome in leaf and free in growth, though to do well it must, like all the large-leaved things, be protected from strong winds. If this Aralia be planted in a dwarf and young state, it is likely to give more satisfaction than if planted out when old and tall. Prefer therefore dwarf stocky plants when planting it in early summer. It should have rich, deep soil and plenty of water during the hot summer months. For the public gardens of Paris it is kept underground in caves during the winter; but in private gardens it will doubtless be thought worthy of a place in the greenhouse throughout that season. In Battersea Park a bed of *A. papyrifera*, thirteen feet in diameter, attained a height of five feet, from cuttings struck in the spring of 1868. The plants were left out all the next winter, and, although killed to the ground, the thick fleshy roots next season

The Chinese Rice-Paper Plant.

produced numerous strong shoots or suckers. These were produced irregularly, and so numerously that they had to be thinned out in many places; a few spaces only requiring to be filled up. It is easily increased by cuttings of the root, and is usually planted in masses, edged with a dwarfer plant; but as a small group in the centre of a bed of flowers, or even as a single specimen in a like position, it is very effective. In some places it survives the winter out of doors, though as a rule it is better planted from year to year.

THE KITCHEN GARDEN.

THE CUCUMBER—ITS CULTIVATION AND USES.

(Continued from p. 612.)

CULTIVATION OF THE CUCUMBER IN THE OPEN GROUND.

THE growth of the Cucumber in the open air has for many years past been a matter of considerable uncertainty, for where one person has succeeded fifty have failed. The reason of this is not very apparent, but the fact is not the less manifest on that account. Twenty years ago, raising a few plants on a slight hot bed or ridge as it is called, putting them out and covering them with hand-glasses, training them with very little trouble, and cutting quantities of fruit through the summer and autumn was a common occurrence achievable by any one; now the gardener who can present a good ridge of plants and cut quantities of gherkins for pickling, and larger fruit for general use is a very fortunate individual. At that time to see Cucumbers by the cartload in July, August, and September in our principal markets was a usual and annual thing. Then the market gardeners in Bedfordshire—at Biggleswade, Sandy, and other places—used to grow them by the acre, by merely manuring and ploughing the land, throwing it into raised ridges, sowing the seed in patches four to six feet apart, and attending to the plants with ordinary care. So managed

they were found to be a remunerative crop; but now outdoor cultivation is so uncertain, that it is to a very large extent abandoned. The reason why it is so is not easy to explain, for though some contend for a change of season, there has certainly been no change within the last twenty years that will account for the failure, while a finer season than that of 1868 was never known. Since the spread of the potato disease the Cucumber appears to have lacked constitutional vigour, and in consequence to have suffered not from one disease only, but from several diseases, some of them so virulent in their attacks, that a plant perfectly healthy in the morning may be dead at night. These diseases, however, will be more fully described in a subsequent page, our duty at the present time being to make such arrangements as may be the most likely to ward off, or at any rate mitigate, the virulence of these unwonted visitations.

The first thing, then, will be to provide such an amount of fermenting material as shall not only form a good ridge, but shall have the property of maintaining a gentle bottom heat for as long a time as possible. Thus, as this preparation will not be required before May, we should for some time previously collect all the vegetable refuse of the garden, such as leaves, weeds, prunings of trees, short grass from the lawn, &c., and these should be thrown into a heap with an equal quantity of horse-dung. Mix the whole carefully together and turn it weekly, so as to promote regular and steady fermentation. By the middle of May the prepared dung will be ready to form into a ridge. Formerly we used to make our ridges about four feet wide and eighteen inches deep, sinking the bottom a foot or so below the level of the surrounding soil, and casting that over the bed for the plants to grow in. Now a bed of wider dimensions is found preferable, and hence we should recommend that the ground be excavated seven feet wide and one foot deep, and of any given length, banking the soil around the excavation so as to protect the fermenting material from cold winds. In an excavation of this kind place some rough sticks in the bottom for drainage, and then make up a bed of the material before recommended, two feet thick, making it firm as if formed for a hotbed. When the heat has subsided sufficiently, place upon the mound a double row of mounds for the plants, each mound being three feet from the side and five feet apart. The mounds should be of sufficient size to receive a full-sized hand-glass, and about a foot deep, say a barrow-load to each hill. To insure success these mounds should be formed of good soil, say three parts of fresh loam, with which one part of leaf mould or mushroom dung may be mixed. We find an advantage in using the latter, as it generally results in a fine crop of mushrooms being produced in the autumn months. When the soil is of the proper temperature, 75° to 80°, the plants which have been previously prepared may be ridged out, giving a little tepid water to settle the soil, covering the plants with a hand-glass, and shading them during sunshine until such time as they are established.

The after treatment of the plants will consist in giving air on, mild bright days, watering when necessary, say once or twice a week, with tepid water, and stopping and training as the plants require it. It will, however, be found a good plan to confine the plants to the hand-lights until they get thoroughly established; in fact, not to let the branches out until such time as more room is absolutely indispensable. Then harden them by giving air more freely for a few days, until at last the lights may be raised upon three bricks placed on edge, where they will remain throughout the season. We regard it as indispensable that the hand-glasses remain over the plants throughout the season, as we are convinced that the protection of the collar of the plants from cold rains and extreme atmospheric changes, is an element important to complete success. Before training the plants it will be necessary that they be earthed, and for that purpose, as soon as the heat of the bed has sufficiently subsided, place the soil from the excavation over the bed to the depth of nine inches or a foot, and make it tolerably firm. It is, however, desirable that the mound in which the plants are placed be kept a few inches above the surrounding soil so as to prevent the water becoming stagnant around the plants. Before training the plants, it will be found a good practice to mulch the ground with short

grass from the lawn, two or three inches in thickness, not only for the purpose of retaining heat and moisture, but also to keep the plants clean in stormy weather. A friend of ours, a very successful grower, in addition to this mulching with short grass, thatches it over with clean stable litter, fastening that down with long thin sticks or laths pegged firmly over it. In this manner the heat of the bed is very much husbanded, which is certainly an advantage. The only drawback is that the straw, from its colour, is not so absorbent of sun heat as the soil would be, but if the warmth of the bed is maintained that advantage can be dispensed with. Training is an important point in the management of the ridge Cucumber, and for that purpose a stock of hooked pegs, six or eight inches long, must always be provided ready for use. Place these over the branches, but while you endeavour to fix the latter firmly be careful in so doing not to bruise them, and a week after the plants are established it will be necessary to go over them and stop all the strongest branches, but leaving the weaker ones to gain strength. As a rule the branches may be stopped to one leaf before the fruit, but if they are very strong then to the fruit. Take care to prevent the branches becoming crowded; that is, do not retain more than the leaves produced upon them can be fairly exposed to solar influence. Sometimes a large branch may be removed with advantage to make room for the younger ones, and this will be found good practice, the object being to provide a succession of young wood all over the plants.

With reference to watering it will be advisable to sprinkle the plants in bright warm weather every evening just before the sun leaves the ridge. This will be best done with a fine rosed watering pot, and it is indispensable that the water be warm when used. The watering at the root must be governed by the weather. With the bed mulched and thatched so much will not be required as if the ground was exposed, and hence upon the average, a soaking of water at the root once a week will be sufficient, even in hot weather; let it, however, be a soaking sufficient to wet the whole soil, and the temperature of the water must not, at the time of application, be less than 80° of heat. When the plants are in full bearing alternate waterings of liquid manure may be used, and this can be best prepared by immersing equal portions of cow and horse dung in a large tub or cistern, stirring it daily for a week or more, and then clarifying it by throwing in a lump of quicklime. The manure water should be perfectly clean, and be used in the proportion of one to four of clean soft water. So managed, with an ordinary season, ridge Cucumbers may still be successfully grown, and be made a remunerative crop. Where hand-glasses cannot be had a very good and cheap substitute may be extemporised by forming a framework of hoops in a conical form, say thirty inches in diameter at the base and eighteen inches high; this covered with oiled calico or tiffany will form a very good protecting material.

A.

(To be continued.)

The Chiswick Trial of Peas.—The ground selected for this trial has been thoroughly prepared for the purpose, and is well open to sun and air. The white round kinds are sown just beyond the orchard house in rows about five yards in length and five feet apart. There are two lines of each with a path down the centre. The sorts commence with Ringleader and Firstcrop, and end with goodness wonders what. All the first earlies are in full bloom, consequently they are beginning to be interesting, although the actual test of merit must be left until the period of podding. Near the back of the old council room is a large piece of ground covered with peas, and here there are four rows devoted to each sort, among which are Blue Rounds, Blue Wrinkled, and White Wrinkled Marrows. Birds, slugs, and mice are very destructive to peas, but so far those here have been kept clear of such depredators. Nearly two hundred kinds, we believe, are on trial, from among which surely something good may come. It may be named that it would facilitate the opportunities of comparison if similar sorts were grown side by side, instead of having tall and dwarf mixed. Some prefer dwarf kinds, and would like to compare them closely, others have a strong penchant for tall kinds, and would like to have them in close contiguity: this is the only exception I have to take to what otherwise must be a capital trial of peas.—BETA.

GARDEN DESTROYERS.

BARK-BORING INSECTS.

(Continued from p. 568.)

(*SCOLYTUS DESTRUCTOR*.)

The number of species of bark-borers of that class, of which the *Scolytus destructor* is the type in this country, is considerable, and we often see trees suffering, and bearing traces of insect-mischief done by them, without any insects being visible at work. We see little round holes in the bark, as if made by a lead pellet of shot, and on tearing off a portion of it we see grooves and galleries, or eaten spaces, but we may fail to set eyes on the creature that has made them. It has perhaps left the galleries and flown abroad. They may be the work of former years, or the insect may be there all the time, but concealed from view. It is desirable, therefore, that in such cases we should be able to say, from an inspection of the bark or the galleries, what insect has made them, and it so happens that almost every different species has a different mode of working, which is capable of recognition.

The workings of some are mere irregular excavations, where, as it were, they clear all before them, leaving a sinuous or curved margin. The greater majority of bark borers, however, form regular galleries of a definite and constant character. These consist of two portions; one a wider main gallery, all of one width, made by the parent beetles, in which the female lays her eggs at regular but close intervals; and the other of smaller galleries diverging from it, more or less, in a herring-bone fashion, small and slender at their starting point from the main gallery, but increasing in width as they go from it, and ending in a terminal cell or bed. These have been made by the young larva, and the terminal space is where they pass into the pupa state, and undergo their metamorphosis into beetles. Now these galleries differ in their position; some have the main gallery always in a longitudinal direction, going upwards in the same line as the tree, and the grub galleries of course transverse (see fig. 1). In others the

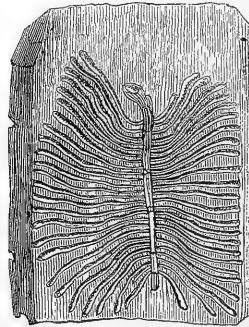

Fig. 1.

main gallery takes a transverse course, running in a direction as if to go round the tree; in many instances diverging from a point obliquely to the right and the left, like a ~~, and going as if to embrace the tree. A third set have several main galleries radiating from a central point, where the beetle entered, and to which it has returned again and again, and has started afresh on each occasion. A fourth has them penetrating directly into the tree. Mr. E. Perris, in one of his papers on the insects of the Maritime Pine (*P. Pinaster*), has given a list of the principal xylophagous insects falling under each head, and although perhaps it may to some of our readers seem too technical for our pages, to others it may be convenient to have a handy reference to the different kinds. It is not long.

1. Main (or mother) galleries, as they are called, longitudinal; galleries of the larva transverse, but capable of becoming longitudinal if the diameter of the tree interferes with their transverse

extensions. The insects following this plan are *Scolytus destructor*; *S. multistriatus*, *S. Ulmi*, *S. pygmaeus*, *S. rugulosus*, *S. pruni*; *Tomicus typographus*, *T. stenographus* (often sub-radiate), *T. laricis*, *T. acuminatus*, *T. Cimbrc*, *T. hispini* (mother gallery often spiral), *T. ramulorum*, *T. villosus*, *Crypturgus pusillus*, *Hylurgus piniperda*, *H. ligniperda*, *Hylastes palliatus*, *Hylesinus Thuya*, *H. aubei*, and *H. Retamae*.

2. Mother galleries transverse; larval galleries longitudinal:—*Scolytus intricatus*, *Tomicus suturalis*, *T. curvidens*, *T. bicolor*, *Cryphalus Tilii*, *Hypoborus Ficus*, *Polygraphus pubescens*, *Hylesinus oleiperda*, *H. crenatus*, *H. varius*, *H. Spartii*, *H. vittatus*, *Dendroctonus Hederae*.

3. Mother galleries radiating or starred; larval galleries perpendicular to the part of the mother gallery where they leave it:—*Tomicus bidentis*, *T. Saxesenii*, *T. chalcographus*.

4. Mother galleries irregular; larval galleries entangled:—*Cryphalus piceo*, *C. abietis*, *Dendroctonus micans*.

The penetrating galleries are of two kinds, one where each serves for one larva, as *Xyloterus domesticus*, *X. lineatus*, and *Tomicus dispar*; and another where the same gallery serves for several larvae, as *Platypus cylindrus*, *Tomicus monographus*, *T. dryographus*, and *T. eurygraphus*.

Although so many of the above make their galleries after the same types, most of them can be distinguished from each other by some variation in the style of their galleries, or by their size, or length, or depth, or closeness to each other.

As already said, *Scolytus destructor* belongs to the first type, where the mother-gallery is longitudinal; fig. 1 represents this. The parent will be found making its mother-galleries early in June. In some bark-boring insects both male and female parents are found inhabiting the same gallery, but in *Scolytus destructor* the male is present in the gallery only for a short period; and he would appear not to assist the female in eating it out, but to join her only for a short time after she has made some progress. The mother-gallery is usually about three inches long (sometimes a little longer or shorter), and as deep as the bark will allow, lying partly in the bark and partly in the wood itself. The insect takes about three weeks to make it; she lays her eggs along each side of it. These vary in number. Dr. Chapman, who has well studied the subject, has met with more than 160 in one, but usually they do not exceed a hundred. They are covered by the *débris* (frass) which remains in the gallery.

The young larvae feed for about a month, and then make and settle themselves in the wider space or cell at the end of their gallery. Many go into the pupa state about the end of July, whence they emerge as perfect insects in the month of August; but a great number also pass the winter in their cells still in the larval state, and do not become beetles until the following month of May. It has been pointed out by Dr. Chapman that those larvae which are not to come out until the following year make a deeper cell at the end of their burrow than those that undergo their metamorphosis the same summer, the former making their resting-place nearly half an inch deep in the solid wood, whilst the latter make it in or only immediately below the bark. The deeper position of the former not only protects them from the heat of summer and the cold of winter, but also from the attacks of birds and other enemies when the bark, which has been loosened by the burrowing of the *Scolytus*, falls off from the action of the weather; and the very similarity of the *débris* which closes their holes and stops up their burrows to the wood itself, which in the bark makes their position by its contrast very observable, serves in the wood to screen them from view.

Dr. Chapman very naturally remarks that "the object though not the cause of this difference in instinct between the beetles emerging in autumn, and those remaining as larvae until spring is obvious"; but although this seems on the first blush a remarkable example of instinct, on further reflection it rather appears to us that there is neither instinct nor object in the matter, but that it is only a natural result of their relative positions. Those larvae that happen to make their resting-place, in which they compose and repose themselves when full fed, in the bark, are of course nearer the surface than those that happen to go into the wood, and are more open to the developing influence of the heat of the sun and air, &c., and it is probably in consequence of this that they come out first. Those that are

deeper being retarded until cold weather comes on, are, by it retained torpid until the return of heat, and also, by the very same means which kept them back, preserved from the too great effects of the cold.

The larvae are without feet, and much thicker near the head than towards the tail; they are white, with a yellowish head, with brown mandibles and mouth. The perfect insect is black, with pitchy-coloured or reddish elytra. The accompanying figures (figs. 2 and 3, which respectively show the insect magnified and of its natural size) enable us to dispense

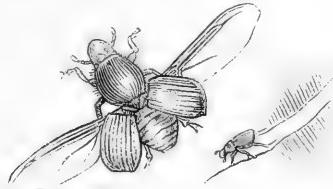

Fig. 2.

Fig. 3.

with a description. We shall only point to one or two peculiarities in its structure, which are common to it and all its allies, and which are interesting from their remarkable adaptation to the mode of life of the insects.

The mandibles are short, strong, and toothed; the head is firmly attached to the prothorax; the antennae are short, and capable of being folded up under the head; and the prothorax is often provided with a roughness which makes it like a file. The extremity of the elytra has oftener still a roughness or teeth, or, as in the case of certain species of *Scolytus*, the metasternum is provided with a point, all important arrangements to provide it with a fulcrum or *point d'appui* from which to put forth its strength in working its way in its mining operations. The feet are short, flat, often toothed or shaped like a rake. The body is nearly cylindrical. One can see that it would be very difficult to organise in a more harmonious manner insects destined to perforate bark and wood, and to excavate galleries.

A. M.

Slugs.—Many complain of the injury done by slugs this season. They are supposed to be more numerous this year than usual, because there has been little frost to kill them. This, I think, is a mistake. They are more numerous because they breed faster in a mild season; not that they are killed by frost. Everyone knows that quicklime dusted on the ground in early morning is a good remedy; but to be effectual it ought to be repeated within an hour, because the slugs have the power of casting their skins, and after getting rid of the lime, will seek shelter. Of course, if the ground be covered, this will be difficult. But lime is a remedy which cannot be used in flower gardens. The best trap I know has been prepared in the following manner: Get some Cabbage leaves, warm them in an oven till bog's lard will spread on the surface; place them overnight near your favourite plants, and almost every slug will be found under them in the morning. It is hardly necessary to say that there must be no salt in the lard.—I. R. PEARSON, Chitwell.

Mice as Garden Destroyers.—The large bull-headed grass mouse eats its way, nibbling innumerable roads and runs in every direction, through old pasture and meadow grass. Its most destructive form of depredation is that of nibbling the bark of young plantation trees, coppice-wood, hedgerows, &c., sometimes destroying many acres. I have seen fine healthy plantations and holly hedges entirely destroyed by these mischievous vermin. The depredations of the field or garden mouse are too well known to farmers and to us gardeners, through their activity in digging up whole rows of peas, beans, radish, and other seeds, by their stealing all the best fibrets, the walnuts, chestnuts, beech-nuts, acorns, common laurel-berries, Portugal laurel-berries, the hard kernels of holly-berries, thorn-berries, and a host of other berries and seeds, and hoarding the same for winter-store. They will get into cucumber frames, pits, or houses, dig up newly-sown seed of both cucumbers and melons; and, what is still worse, find their way in when the plants are in full vigour and bearing fruit, and make sad havoc; and, to crown all, they will gnaw fine plants in full bearing right through near their roots, killing and destroying the whole at once, and they will act in the same way with various other kinds of plants, both in-doors and out.—James Barnes.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN ROOMS.

(Continued from page 616.)

In rooms the new growth of most plants commences about the end of February, and consequently the necessity for watering them will be greater from that time forward than in autumn and winter.

Lastly, the necessity for watering varies with the organization and development of particular kinds of plants. With respect to organization, it is well known that many succulent plants, as for example, cactuses, are covered with an epidermis which has few pores, so that at the period of rest they transpire very little moisture, and so can remain for a long time without any water. But during the period of vegetation these plants require abundance of water. Other succulent plants, which possess true leaves (as the Mesembryanthemums), must be watered like other plants, and will die if kept too long dry.

The greater number of bulbous plants require abundance of water during the period of vegetation. After the seeds are ripened, water must for the most part be withheld altogether. There are also plants which grow in water and marshes which must be similarly placed when under culture; others again, such as ferns and orchids, which during the season of vegetation like a moderate degree of moisture; others again, as evergreens, which even at the season of rest, when they are forming new flower buds, must be guarded from too great dryness.

Of very great importance to the health of the plants is the time of the day at which they should receive water. The best time is in the morning and evening, and even in autumn and winter the morning, so that the superfluous moisture may be somewhat absorbed in the course of the day. In spring and summer towards evening is the best time, as under the influence of the coolness of the night the water given will be distributed over all parts of the plant. After such a watering in the evening, plants which had been dried up during the heat of the day recover themselves in the course of the night. But if they are watered in the morning the succeeding evaporation during the heat of the day will prevent the plants from properly recovering at night from the drying up they have received during the day. In the case of plants placed on sunny window sills, flower stands, and balconies in summer in the open air, watering in the evening is the chief condition of a vigorous growth. In such positions, for the sake of the better recovery and preservation of the plants in hot weather, after the evening watering should follow a sprinkling overhead, which by checking evaporation, promotes in a very great degree the rise and flow of the sap to all parts of the plant. This may be repeated the following morning. This sprinkling overhead is a very powerful stimulus to a strong luxuriant growth, therefore, where the locality permits, it should be employed along with the watering proper. It is necessary when the shoots droop in consequence of too great dryness. In the glazed cases and in plant houses it may be employed for the purpose of producing a moist atmosphere.

For sprinkling, the amateur should use a well-made brass syringe, as those made of tin neither work well nor last long. Specially adapted for room culture, where it is desirable to moisten the plants without wetting the floor, is an instrument of recent construction, called a "refresher." The simplest form of this instrument requires some effort of the lungs; but in improved forms, the open end of the tube is connected by a thin tube of gutta-percha with a hollow gutta-percha ball. By squeezing this ball the necessary blast of air is produced, and the operation is performed with much less effort. These improved "refreshers," with glass or brass tubes, are to be had at the surgical-instrument makers, as they are now frequently used by physicians. For sprinkling plants in rooms they are unquestionably the best instruments, as with them the water can be applied in the smallest quantity in a fine dew to all the leaves without wetting anything else in the room.

Although morning and evening are said to be the best times for watering, this may be done during the day in dull weather;

but in sunny warm weather it is not suitable for plants which are exposed to the sun; the balls of these being considerably heated, are liable to be suddenly chilled by the cold water, and in the case of tender evergreens, such as *Ericas*, &c., the result may be fatal.

From this follows the rule, not to water plants which are exposed to the sun as long as the sun shines on them, or at least not till the day declines. Should individual plants which stand in such positions exhibit signs of too great dryness in the course of the day, by the drooping of the points of their shoots, they should be moved into a shady place and sprinkled at intervals for some time, the ball being also well watered. As we have in preceding pages described the manifold circumstances which determine the greater or less supply of water to plants grown in pots, we shall now add a short summary of the results, for practical purposes, which may be useful to beginners:—

1. Always use soft river or rain water.
2. The temperature of the water should always be at least as high as that of the room.
3. By comparing the appearance of the soil when in a dry and in a wet state, and by noting the aspect of the plants under the same circumstances, an opinion may be formed as to whether water is necessary or not; and the plants should be watered on the first appearance of dryness, or even before it.
4. In watering, see that the ball is thoroughly soaked; this will be most certainly effected by absorption from the saucer.
5. In autumn and winter, water in the morning; in spring and summer, in the evening only. In dry, hot weather, where the locality permits it, employ a sprinkling in the morning and evening in addition to the watering. Plants which have become dried in the sun should be removed into a shady place, and after a while sprinkled and watered there.
6. When there is any doubt whether a plant is so dry as to require water or not, the following considerations may be a guide:—If the drainage is good, or the soil loose and light, or the pot small compared with the plant, or the ball full of roots, or the weather warm and dry and the position exposed to the sun, or the air in the room very dry in consequence of the great heat, and if the plants are in good health and full vegetation, in such a case it will be proper to water, whether any or all of the above conditions exist. Greater care must be observed, and in doubtful cases water must be withheld altogether, when the drainage is imperfect, the soil heavy, stiff, and rich, or when the plants are in very large pots, and the ball not yet filled with new roots; when the weather is cool and in moist, the position shady, or when the atmosphere of the room, is more moist than usual, or when the plants are shut up in glazed cases and double windows in an atmosphere kept moist by sprinkling. But the greatest caution must be observed when, in addition to the above, the plants are sickly or in a state of rest, in either of which conditions they will require very little water. Plants which have a fleshy stem, root, or root-stock, or a bulbous root, require no water while they are in a state of rest.—Dr. Regel.

(To be continued.)

PRACTICE v. SCIENCE.

I WAS much interested in Mr. Newman's note (see p. 548), and desire to say a word to point out that this seeming confusion between practice and science arises from a false rendering of the words "science" and "practice," by scientific men themselves. They divide books and men wrongly, as I think, into "scientific" and "practical." This is frequently done in garden literature. Is it any wonder, then, that gardeners get a notion that "science" is something very different from anything they are accustomed to deal with, and that they themselves belong to quite a different class of workers? This awkward and mischievous barrier should be broken down; and everybody should understand that science simply means knowledge, that the knowledge of the gardener does not differ in kind from that of the highest scientific man, and that the division of ideas into "scientific" and "practical" is totally false in principle. What is right in theory is right in practice; what is sound in practice is correct in theory, and vice versa. But it will not be easy to make this clear to the less educated, till "scientific" men so-called help to dissipate the erroneous notion that they differ essentially from the simplest and most unlettered observer. J. L.

DINNER-TABLE CENTRE-PIECES FOR FLOWERS.

If you go into any shop where vases for flowers are sold, it is quite the exception to meet with a form that, when furnished with flowers or foliage, will not obscure the view across the dinner-table. All the greater, consequently, is the pleasure to a collector of these articles when he meets with such a form as that depicted in the accompanying engraving. I know not whether the design is registered; but it is only at one of the London glassworks that I remember to have seen it. The artist has represented four little vases, surrounding the large glass globe, which contains clear water. In that, however, he has erred, for this centre-piece is only made in two sizes, of which the larger has five little vases, and the smaller size has only three. In each, these little vases are placed at such a height that, when filled, they present no interruption to sight or conversation. Upon one occasion I used three of the large size, placed in a line down the longer diameter of an oval table,

Dinner-table Centre-piece for Flowers.

twenty-one feet long by ten feet wide, and round the central one were placed four of the smaller size, an arrangement which the great width of the table well permitted. The same table has frequently been dressed with other forms of vases; but, taking into consideration the few flowers required to decorate one of these compared with many other kinds of vases, I never was more pleased with the general effect of the decorations, than upon the occasion when seven of these centre-pieces were used.

W. T.

PASSION-FLOWERS FOR THE DRAWING-ROOM.

These are not very promising subjects for cutting, as the individual flowers generally last but one day, and close with the sunset. Still, many of the flowers when gathered from the plant seem, partially at least, to lose this provoking power of early closing, and the bright light of brilliantly-lighted rooms keeps them open a few hours longer—that is, long enough for an evening party. Unless, however, at the end of the season, when the vital functions seem weakened, and this power of closing the flowers with the day appears to decline with the diminution of growing force, passion-flowers are not to be depended on for bouquets. It is rather too much of a risk

to centre a bouquet with a gloriously-fringed blossom of *Passiflora quadrangularis*, when it may collapse into a hard ball, of no particular beauty of surface, before it is presented. The smaller *alata* is equally uncertain, and most of the other thinner varieties still more so. Still, both these passion-flowers, and many more, are very useful for cutting or gathering. Some dishes, glasses, or baskets filled with blossoms of *quadrangularis*, fringed with its own leaves, are a grand sight; while the perfume will fill the largest room or house with spicy fragrance. The flowers keep open best if gathered two or three hours before noon, placing them in water or on damp moss, and slightly sprinkling, or rather dewing, them over with water. *P. alata* does equally well, or better, under the same treatment. It is not so large, but very like the other in all respects. Most other varieties will keep open for a shorter period, and with less certainty, under similar treatment.

But such varieties as *P. Loudonii*, *Kermesina*, and *racemosa* or *princeps*, are more effective cut in branches of any desired length, the leaves and flowers depending from baskets, vases, &c., or twisting around them. With one end in water, the flowers will frequently keep open, as in the case of single flowers; and should they close, the closed flowers, with the advancing buds and leaves, are very beautiful. My favourite passion-flower for foliage is *Kermesina*. It is all that a leaf and branch need be for effective decoration. Fine, pliable, with small, exquisitely cut and coloured leaves, its elegance and beauty are beyond praise. And it matters little whether the flowers of *princeps* are open or not. They have a most unique effect depending over the sides of high stands, or encircling their stems. The leaves are likewise finer, though larger, and not of such a beautiful green, as those of *P. Kermesina*.

P. princeps flowers freely when properly treated. It should not be pruned much, and none of the old flower stems must ever be removed. It flowers again and again on the same flower stalk; hence, unless for use as cut flowers, none of these should ever be removed. In the winter season they hang in withered-looking bundles; but in the early spring the sap floods the channels with new life, and a fresh raceme is thrown out from the extreme point of last year's flower stem. And this goes on year after year, while other pendent of dazzling brightness spring forth near the base of the flower stems. Those also that have been shortened back sometimes break into fresh clusters of blossom. Many of them, however, die back: and, unless obliged to cut for the flowers, none of the old flowering branches should be cut at all. When the new flower-stem shoots forth, any dead points beyond it may be cut off. Another great advantage arises from this successional elongation of the flower-bearing branchlets. Almost any length of raceme may be secured for twisting round the stems of stands or vases. This enables the decorator to place the flowering blossoms of this brilliant plant in telling positions to which shorter flower stems, that must from necessity have one end in the water, could never have reached. Many of the common passion-flowers have beautiful foliage, and sometimes carnea and other varieties will keep open throughout a long night. Though these lack the brilliancy and size of those I have indicated, the whole of the passion-flowers are beautiful and interesting. While I advise that the massive cup-like sorts, such as *alata* and *quadrangularis*, should be placed simply on their backs on damp moss or in water, occasionally profusely-flowered branches of either have a grand effect, depending over the sides of silver stands or vases encircled with *Stephanotis*, or other white or light-coloured flowers.

T.

Clay a Foundation for Table Bouquets.—On examining the construction of some table bouquets the other day, I found that little round balls of wet clay had been placed in small flower-pot saucers, and that into the clay the flowers had been inserted. These were so arranged with sprays of ferns, and graceful flowing foliage, as to completely hide both saucer and clay, and present an appearance scarcely attainable in bouquets made in the ordinary manner, and placed in glasses or vases.—W. F.

Caladiums for Room Decoration.—The value of these is not sufficiently known. The beauty of the form of the leaves of well-grown plants is of the highest character. With this important, if not most important, quality in plants for indoor decoration, they combine a variety of beautiful mottlings and shadings of colour, which seem to great advantage in daylight. The plants are easily grown, and increased rapidly. The seed is a rarity, and is of no account, which is not by any means the case when rare and expensive plants are employed. The great variety in the size of Caladiums is also in their favour; among them we may find subjects fitted for the smallest épergne or the largest recess.

Asparagus for Cutting.—The fine foliage of Asparagus is very useful for borders, and I have seen sprays of it used with advantage for the backs of "button-holes." There is also another use for which it may be devoted, when fat, to be eaten, if it is not required in pots for the stand, and covered with moss, or other green covering, placed on the surface of the pots, it forms a graceful object for the drawing-room table, especially among other plants. As it is used extensively for ribbon bedding, I do not see why Asparagus should not be used as occasional plants for the backs of borders, &c. And I am sure it is a positive relief to rest one's eyes on a bed of its graceful foliage, after being dazzled with the glare of a mile or so of the red, yellow, and blue of the present style of bedding.—W. JOHNSON, *Xilburn*.

MARKET GARDENING.

BY H. EVERSHED.

(Continued from p. 623.)

MR. W. W. GLENNY has been good enough to permit me to give an account of his garden farm at Barking. It consists of 150 acres of gravel loam, made rich and friable with manure, and kept in the highest state of cultivation. The farm is entirely in vegetables, with the exception of eighteen acres of permanent pasture, and sixteen of wheat, on the stiffest land, which is furthest from the railway station. At the time of my visit the acreage of the farm was thus appropriated:—Potatoes, 3*1*/₂; permanent pasture, 18; spring-sown and Lisbon onions, 15; cabbage, 12; red ditto, 2; seed-beds, 2; carrots, 7; parsnips, 9*1*/₂; French beans, 6; scarlet runners, 3; vetches and green food for horses, 4; parsley, 1*1*/₂; willow and osier beds, 1*1*/₂; wheat, 13; mangold, 1*1*/₂; peas, 8; asparagus, 1; men's allotments, 1; cucumbers and marrow, 2; seeds, 1; buildings, roads, brook, and small crops, such as sage, &c., 11. Twelve horses are kept to cultivate the farm, convey the produce a distance of eight miles to London, and to cart manure. The sums paid for dung, exclusive of cartage, during the past three years have been—£211. 9s. 3d., £271. 16s. 7d., and £278. 15s. 2d. From four hundred to seven hundred bushels of soot were also used in each year. About one-half of the dung is purchased at three shillings or three shillings and sixpence a ton, and is drawn from London in the empty waggons; the remainder is bought at five shillings per ton, at the railway station or quay. Some other manures, including the spent hops from an adjoining brewery, are also brought on this farm. The live stock consists of a couple of milch cows, and forty or fifty pigs during the winter. The labour bill, including beer, is £1,500, or £10 an acre. At the time of my first visit—June 17th—the number of labourers employed, including ten women, a wheelwright, and a salesman, was thirty-five, and their wages amounted to £30 a week. During the winter five women are employed preparing goods for market, bunching leeks, pulling and bunching greens, putting up onions, &c. The implements of the farm, besides carts and market waggons, consist of common ploughs, a double-breasted or riding-plough for moulding potatoes, beans, and peas, and some hand-drills. A small patent tool, which resembles a Dutch hoe put on wheels, must be mentioned, because its use shows the mechanical effects of dung and good farming in making the surface friable. It is not uncommon for a man to push this little implement over two acres in a day, cutting up all the weeds between the wide rows of the garden crops. A willow-bed supplies bunching rods for tying the bunches of onions, greens, &c. The plants are set at two feet by eighteen inches, and the bed lasts twelve years. Osiers of coarser habit are grown to make baskets for vegetables and fruit. I may note that the cost of the baskets (with a few sacks) used on the farm exceeds £50 a year.

Parsnips are one of the main crops which are successfully grown on this farm. The chief points to observe in their cultivation are:—1st. To sow on land that is least liable to wire-worms and the small creatures—probably slugs—which are said to be invisible to the eye, and which soon make the parsnips so, by eating the young plants as fast as they appear; the remedy for slugs is soot, and the prevention is, sowing on land that is not liable to be infested. 2nd. To take precautions against having forked parsnips, and to grow them of a fine, tapering, marketable shape by breaking the land well up and applying the manure to the previous crop. It is not perfect management to sow after corn, because the land is not then in sufficient heart and tillage; or after clover and grasses; or account of the danger of wire-worms and canker; or after potatoes, because potato-ground ought to yield a crop of greens after the potatoes are off, instead of lying idle till parsnips are sown. They generally follow late cabbages or savoys, which are cleared respectively in November and from Christmas till 1st March. In either case, the field is not touched until immediately before sowing the parsnips, and Mr. Glenny would prefer to plough, scurfy, and sow on the same day, so that the seeds of the crop might start fairly with those of the small nettle, chickweed, grass, and the shepherd's purse, which are favourite weeds in market gardens, frequently escaping the continual hoeing, and almost serving to establish in some quarters the theory of spontaneous generation. Supposing the clearings of the savoys to have been bunched by 1st March, as in 1867 (14th March in 1868, 20th February in 1869), the land is ploughed with two horses and subsoiled with three horses, and is thus moved and stirred to a depth of about nine inches. It is then drilled with a hand-drill as early in March as the state of the weather permits. Mr. Glenny objects to preparing the land in autumn, because it solidifies too much by the time the crop is sown. In garden-farming a stale furrow and a frosted surface are not entirely appreciated, since the made soil of a garden-farm is effectually

pulverised by manure and surface tillage. Parsnips are sown fifteen inches apart in the rows, and the plant is singled at ten or twelve inches. The crop is hoed, singled, and kept clean for forty-five shillings an acre. The hoeing last year had cost, up to 21st June—First hoeing, 5s; singling, 16s. Sd.; second hoeing, 6s. Frost does not injure parsnips. The roots are raised and sent to market from the field, and are in season from November till the end of Lent, occupying the ground longer than any other crop.

French beans often follow early cabbages, without dung. The last of the three successive sowings is made about the 21st June. This delicate plant is impatient of fresh manure, and requires the preparation of a perfect garden tilth. Mr. Glenny always ploughs twice, and for this and similar crops the land should be lightly rolled, to level it and to retain moisture. Drills are formed at 2*1*/₂ feet apart by means of a small hand-plough, or marker, drawn by a man and a boy; women follow, and drop a seed at every nine inches, and the drill is then covered by a man with a hoe. The plants are carefully hoed. French beans grow rapidly, and soon become what salesmen call "old beans." In hot weather they should be gathered every other day, and they are cleared in about four pickings. The latest-sown beans are cut down by the slightest frost. Scarlet runners are generally sown in the last week of April, after greens. The land is ploughed twice, with an interval of two or three weeks. The rows should be three feet apart, and a seed is planted in every foot of the drill. Runners continue to bear until they are cut down by severe frost. When manured, they are liable to become too luxuriant in damp summers; they should, therefore, be planted on good land, without manure. It does not pay to support them on sticks, except when they are grown as a shelter for cucumbers; and instead of giving them artificial support, an upstanding habit is induced by continually topping the vine from the period of its beginning to "run" about the middle of June. Unless beans and runners are gathered when very young, they should be sorted before sending them to market, in order that the broad ones may be picked out.

Cabbages.—A second crop in succession was planted last year, on June 21st, after ploughing in a second and heavy coat of dung with a seven-inch furrow. After rolling the land a line is used in setting the plants, which are put in with a short dibble, at a distance of twenty-two inches by twenty inches. In the case of "collards," which are planted twelve or fourteen inches each way, a light roll after the plough is followed by the "fiddle"—resembling a rake with four or five long teeth—dragged by a boy, to mark drills for the plants. Red cabbages for pickling are planted in October, a yard apart in each direction, and occasionally collards are set previously between the rows in which the cabbages will afterwards be planted. The catch crop is sent to market early in spring, before the ground is required for the main crop.

(To be continued.)

THE ARBORETUM.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE VENETIAN SUMACH (*RHUS COTINUS*).

This forms a highly ornamental, deciduous shrub, from six to eight feet high, and when loaded in autumn with its large, loose panicles of elongated hairy pedicels, it is a striking and attractive object. It is a native principally of the south of Europe, but it is found from Spain to the Caucasus. In the south of Russia and Greece the whole plant is used for tanning and dyeing leather, wool, and silk, yellow; in Italy, about Venice, it is employed for dyeing black, and is called "scotina." It thrives best in a dry, loamy soil, and is readily increased by layering. It was first introduced in 1656. The leaves are more or less round or obovate, simple, alternate, coriaceous, stiff, smooth, bright glossy green, and on long, slender footstalks. They measure from 1*1*/₂ inches to 2*1*/₂ inches in diameter, and remain on the plant until late in the autumn, when they become of a fine reddish-yellow colour. The flowers are hermaphrodite, yellow, or flesh-coloured, and are disposed in large, loose, terminal panicles, with many of the flowers abortive; after flowering, the pedicels lengthen, and become hairy. The fruit is a smooth, veiny, half-heart-shaped white drupe, with a triangular stone inside, and ripens in September. This Sumach, as a shrub for autumn decoration, deserves a place in every garden where there is room to allow it to extend itself on every side.

THE MAGNOLIA HOLLY.

(ILEX LATIFOLIA.)

THE accompanying life-sized illustration of one of the leaves of this fine plant may serve to give some idea of the size and beauty of its foliage. For the opportunity of figuring it we have to thank Mr. Stevenson, gardener at Cobham Park, Surrey,

Life-sized Leaf of the Magnolia Holly.

where, as has already been stated in THE GARDEN, there is a noble specimen of this remarkable Holly. It looks at first sight to be a handsome pyramidal specimen of *Magnolia grandiflora*, such as one sees in the warmer parts of France,

and sometimes near Paris; as, for example, at Madame Pescatore's garden near St. Cloud. It need hardly be said that if the plant attains such perfection so near London as Cobham Park, it is a most valuable subject for planting in the southern and milder parts of England and Ireland.

This Holly, Mr. Gordon tells us, often forms a tree twenty feet high. It is a native of Japan, and was first sent to Belgium by Dr. Siebold in 1840, and the year following it was introduced into England by the late Mr. Joseph Knight, of the Exotic Nursery, Chelsea. The leaves are sometimes nine inches long, the berries are red, and about the size of those of the common Holly. The plant is perfectly hardy, and very similar to the kind called *Ilex Torajo* by Dr. Siebold, and which appears to be only a variety of it. When first introduced it was frequently called *Ilex laurifolia*.

The Tulip Tree.—However hardy the Tulip tree may be in America, I fear it cannot be considered so in many parts of England. In the severe winter of 1859-60, the finest tree here was so crippled that it never recovered; and the Tulip tree is so seldom met with that one can hardly but suppose that its tenderness, assumed or real, has something to do with its scarcity. There are, probably, many deciduous trees and shrubs that would pass safely through much more severe frosts in America than they would in England. Their wood is more thoroughly ripened, whence their safety. The brittleness of the Tulip tree is also doubtless a drawback to its more general cultivation. We have scarcely a high wind, or a heavy rain in the summer, but down comes a limb or two of a Tulip tree, and even the little snow that can lie on their bare boughs, frequently results in similar breakages. I shall be glad to know if others find the Tulip tree equally brittle.—D. T. F., *Bury St. Edmund's*.

Berberis Darwinii.—Few know how well this thrives in drained bog soil. It does well in most soils, but seldom have I seen it equal to a few plants of it which we have here in a bog soil, where it makes finely branched shoots from eight to ten feet long in one season; and when in spring these are smothered with bloom, and surrounded by masses of Rhododendrons in all shades of colour, from white to a deep crimson, the contrast is most pleasing; the colour is so rich and telling, so entirely its own, that there seems nothing wanting to make the picture perfect. It should be planted well back, or it is liable to bury things behind it of dwarfer growth; and do not forget after it has done blooming to head it well in. It makes, too, here and there, grand isolated specimens. I hope this account of it will induce others who have bogs to plant it largely. It seems to thrive even where the Rhododendron looks sickly through too much wet and hard frost during winter. Why not also have miles of hedging planted with it? It is both handsome and effective, and, on account of its spines, quite equal in the way of defence to thorn or quick, which do not do well in bog. Under such circumstances, therefore, this Berberis should not be overlooked.—J. TAYLOR, *Maesgwynne, Whitland.*

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Does Ivy injure Trees?—Although an admirer of the effect of Ivy clinging to the trunks of our forest trees, I suspect that the growth of the trees is retarded by the pressure; indeed I have observed young plants almost overwhelmed by the weight of a year's growth; and your correspondents favour us with their opinion as to the amount of damage, if any, produced by the adhesion of Ivy to the bark of exogenous plants, at different stages of their growth?—E. D. T.

A Remarkable Yew Tree.—The large Yew tree, of which I gave some account in your columns a few weeks ago, is the same tree your correspondent "S. X." alludes to in No. 26, p. 573. I cannot make out the large beech tree he mentions. The largest tree on Longleat estate is also growing in a grove in the same place, and is said to consist of stems of one foot from the ground, thirteen four feet, eight stems five feet up, twenty-two feet; counts upwards of 1,100 feet of timber.—GEORGE BERRY, *Longleat.*

Hardiness of the Umbrella Pine (*Sciadopitys*).—This has stood out here for these last four years, during which time we have had the thermometer at zero, and one night three degrees below that point. Not a leaf was injured. Eight plants were out during the time mentioned, and the largest is eighteen inches high and twelve inches through, but would have been twice this size had it not been cut for propagating purposes. Now, sir, in private establishments there are much larger specimens, where they have been left to grow; nevertheless, this conifer is a hardy grower.—SCOTT, *Merriott, Somerset.*

To the Editor of THE GARDEN.—Can you kindly give me a list of the best Hardy Trees, Conifers, flowering Shrubs, and Herbaceous Plants to grow in ground on the margin of a river, and liable to be flooded?—J. H. —[Of Conifers, the Spruce Fir and *Abies Douglasii* will be best; the white Cedar and *Cedrus atlantica* also stand a great deal of moisture; so does the Silver Fir. Birch, Spanish Chestnut, and Beech will do well; and of under-shrubs, may with confidence play the part of the *Myrsinaceae* of the border. But the *Berberis Aquifolium*. Both the Sweet and Willow and the Silver-leaved Poplar would prove distinctive shaded ornaments of such a position. Limes, Alders, and the finer kinds of Willows would, of course, do well. All the herbaceous kinds of Aster, the golden Rods, the *Epilobiums*, *Eupatoriums*, *Heracleums* will also thrive. So will many coarse herbaceous plants. *Iris sibirica* will look very well in the water associated with our common Yellow Flag.]

THE PLANES.

BY GEORGE GORDON, A.L.S.

VI.—THE VARIOUS LEAVED PLANE (PLATANUS HETEROPHYLLA—LINDLEY).

THIS is a native of the more southern states of North America and California, where, along the banks of the Carmel River, it forms a tree from sixty to eighty feet high, with a stem four feet in diameter. In England it is a round-headed tree, forty feet high, with large, crooked, arms, contorted branches, well furnished with stunted spray, and a stem full of large, protuberant, warty swellings, which give it quite a gouty appearance. From these swellings frequently arise during the summer a number of small twigs or spray, which perish annually, but form at their base woody knots or kernels of various shapes and sizes, with conical fangs at their base, which reach to the wood of the stem.

The Various-leaved Plane is one of the least valuable of the tribe to which it belongs, as it gets more or less injured by even an ordinary English winter, and, as it commences growing early in the season, it suffers greatly from late spring frosts. It succeeds well, however, in the south of France, where it is

The Various-leaved Plane.—Natural size, largest leaf, 9½ inches long, including footstalk, and 7½ inches broad; smallest leaf, 1½ inches long, including footstalk, and 2½ inches broad.

much planted and cultivated in nurseries under the name of the American Plane; and in consequence, it is sometimes called in this country, the French, or tender variety of the Occidental Plane. When this species of Plane was first introduced is uncertain, but it is frequently to be met with from thirty to forty feet high in the neighbourhood of London.

The leaves are of various shapes and sizes; those on young and vigorous trees are in general very large, acutely five-lobed, more or less deeply divided, rounded at the base of the divisions, and furnished on the margin with acute coarse serratures, while a great portion of those on old trees are frequently little more than three-lobed, somewhat rounded in outline, and either nearly entire or coarsely toothed; but all the forms are to be found on the same tree, and all the leaves taper more or less visibly to the petiole, which is long and slender in the larger leaves, but quite short in the smaller ones. When first

the leaves begin to unfold, they are densely coated all over with a rich cinnamon-coloured tomentum, while the adult ones are quite glabrous, with the principal ribs on the under-side frequently of a bright orange colour. The balls, or seed-heads, are mostly in twos or threes, distantly placed along the slender footstalk, and, when fully matured, are large, very downy, and thickly furnished with rather long, stiff bristly points.

Its synonymous names are *Platanus californica*, *occidentalis aurea*, and *occidentalis acerifolia*.

VII.—THE MEXICAN PLANE (PLATANUS MEXICANA—LINDLEY).

LITTLE is known about this kind, except that it forms a lofty tree in Mexico, and has large, palmate, five-lobed leaves, which in the adult state, are thickly covered on the underside with a short silky down.

It has not yet been introduced, and no doubt will prove tender in the climate of England.

THE BORGHESI GARDENS, ROME.

NONE of the gardens of Rome—public or private—can be compared either for beauty, extent, or profuse sculptural decorations with that known as the Villa Borghesi. It must be understood that the term “villa,” as used by Italians, does not mean a house, but a garden. The Villa Reale, at Naples, does not contain any building whatsoever; not even an alcove, or a summer house. It is simply a public promenade, decorated with statuary and fountains, on the shore of the lovely bay, in front of the famous Chiaja. The residence in a villa, if there be one, is generally called the casino, or palazzetto; though occasionally, when an important structure, it is, like a street mansion, styled a “palazzo.” But the villa means the garden, or park, or vineyard, or small farm with which a summer residence is surrounded. The Villa Borghesi, therefore, is the garden-park, in which the suburban palace of the Borghesi family is situated. It lies close to the walls of Rome, and many of its most striking features may be seen from the Pincian Hill.

It was originally one of the estates of the Cenci, but being confiscated to the Papacy during the persecutions of that unfortunate family, it became the property of Scipio Borghesi, nephew of the Pope Borghesi, who reigned as Paul V. The entrance to this beautiful villa—to which the public have free access—is closely contiguous to the Porta del Popolo; and affording, as it does, shady drives and walks of great extent, forms by far the most frequented promenade of Rome. It is, in fact, the Hyde Park of the Romans. But neither Hyde Park nor Kensington Gardens, nor even the Tuilleries or Versailles, can convey any idea of the peculiar charms of this delightful Roman villa. There is a freshness and vigour of vegetation about the suburban *delizie* of Rome, that the close proximity of a large and populous town almost always seems to tarnish and check; while the immediate vicinity of Rome, with its great native and foreign population, seems to produce no check whatever upon the fresh verdure of the Villa Borghesi; at all events not in early spring; for the beautiful Apennine anemone, with all its enchanting varieties of hue, from the deepest lilac to the palest azure, makes its way through the tufts of coarse grass in luxuriant profusion; as does the crimson cyclamen, many species of Scilla, and several kinds of European orchids; all of which are so shy of the smoke of our northern cities, and of the fatal tramp of their thousands of destructive feet; while in the Villa Borghesi these denizens of the forest wilds seem to enjoy themselves and flourish with the same profusion and fragrance as in the woody dells of the secluded country.

One of the grandest features of this Roman garden is the lofty growth of the cypress, which, while with us it is little more than a shrub, assumes in Italy almost the dimensions of a forest tree, towering to the height of the largest poplars. Its dark forms rising like sharply-defined spires against the blue Italian sky suggested to Shelley the epithet, “sky-clearing cypress;” and those who have noted the effect of that tree in Italian landscape, will at once acknowledge both the poetry

and the realism of the description. Another striking characteristic of the Villa Borghesi, is its noble avenues and groves of Illices, meeting in matted foliage overhead, and forming—

"A pillar'd shade,
With echoing walks beneath."

Still another feature of purely Italian character is that formed by the tufted heads of the stone pines, as they are shown in the engraving which serves as our illustration. Those southern pines are the delight of artists, who could not conscientiously paint an Italian scene without one or more of them being made to form a marked feature in the composition.

As in all Italian villas, statuary and fountains are profusely introduced as legitimate, and indeed indispensable, decorations. In the Villa Borghesi they are so well managed, as to seem

THE INDOOR GARDEN.

WHY CAMELLIAS DROP THEIR BUDS.

No plant is easier to manage than the Camellia, so long as it is in perfect health—few more difficult to resuscitate when sickly. Then it is that the buds drop prematurely, leaves become flabby and pale, and the whole plant has a "lack lustre" appearance, anything but satisfactory to the cultivator. This may arise from several causes, such as unsuitable soil and bad potting, too much water or the reverse, and insect attacks upon the roots. Of this latter cause of failure I had an example very recently. A fine vigorous plant of double white was moved into a larger pot, using soil from the same place from which I had been in the habit of obtaining it for some years past with the best results, the only difference being that this soil was used fresh from the field, while generally I lay it by for a few months to rot and ripen. The con-

View in the Borghesi Gardens, Rome.

really a necessary part of the *mise en scène*. The casino, or rather palace, is not a very ornamental building, but it contains a fine collection of statuary and paintings, though the more celebrated gems of the collection are not there, having been allowed to remain in the Louvre after the general return of the Napoleonic spoils of war in 1815. This arrangement was effected in consequence of the French predilections of the Borghesi family through their alliance with the Bonapartes, the noble Italian proprietor receiving a rent for the use of his works of art from the French Government.

There are many points in the Borghesi Gardens fully as picturesque and attractive as the one selected for our illustration, but the solitary sample is sufficient to convey a good general idea of the style in which the gardens are laid out, and of the effect produced.

NOEL HUMPHREYS.

sequence has been that the plant started weakly, the young growth flagged when not shaded, and the old leaves began to fall off. In this state of affairs I turned the plant out of the pot, and found not a root had been made, but on the contrary, those outside of the old ball had been eaten, so that an active rootlet could not be seen. On examining the soil and drainage more closely, I found quantities of wire-worms, and these, no doubt, had been feeding upon the young roots. Removing the new soil, and as much of the outer portion of the old ball as I could with a pointed stick, the plant was repotted in carefully-selected soil, and now it is progressing as well as could be desired.

I was requested once to take charge of a plant that had fallen into bad health. Formerly it had been a very handsome plant, with a head five feet in diameter, and had been purchased at a cost of fifteen guineas. When I received it all the foliage upon it would not have made a screen for a tom-tit, though it was in a tub containing little short of half a cubic yard of earth. Taking hold of the

stem I lifted it out of the soil, when I found that all the active root which it had would scarcely have filled a nut-shell. Clearing away as much of the old soil as I could, the plant was repotted into a thirteen-inch pot in a compost of turfy loam, leaf mould, and sand, with a dust of charcoal in small pieces, lumps of charcoal being mixed with the drainage. This compost was made as firm as possible, firm potting being a great point with me in the cultivation of the Camellia. Placed in a viney just started to be forced and damped three or four times daily with tepid water, it soon began to show signs of growth, and now it is in perfect health, and has flowered abundantly. Camellias, however, in bad health are, as I have already said, exceedingly difficult plants to manage. Some plants will start at once with renewed vigour, others will remain sulky for months, possibly years. Though shaken out, and the roots washed and repotted in suitable soil, some small plants made scarcely a shoot the first season, but in the autumn I found the pots nearly filled with healthy roots, and the next season they started vigorously. Those therefore who have sickly plants will find it best to remove as much of the old soil as possible, to repot in suitable compost, place the plants in a mild moist atmosphere and rather shaded, and wait patiently for the result. Coddling is useless, and properly potted the less the roots are interfered with the better. With reference to watering, enough is as good as a deluge, and with amateurs I believe more plants are destroyed by daily dribblings than by giving either too much or too little. The right thing when a plant requires water—and that is difficult for most people to know—is to give sufficient to soak the whole soil in the pot thoroughly, and then let it stand until a second watering is necessary. To the practical cultivator knowledge of this kind is intuitive, as he can see in a moment when a plant requires water, and he rarely errs by giving too much; but the amateur or handy man is guided by custom, and waters whether the plant requires it or not. The best plan, if the plant is properly potted, is to test the humidity of the soil by ringing. Rap the side of the pot sharply with the knuckles; if the sound emitted is sharp and sonorous, the ball is dry; but if, on the contrary, it is dull and heavy, no water will be required. At Chatsworth each man when watering carries a little wooden hammer, and is guided by the sound emitted, after striking the side of the pot with it, as to whether the plant requires water or not, and the quantity to be given. Another plan is to weigh the plants or rather pots, by lifting each with the hands; but that is a troublesome process. If, however, the pot feels heavy, no water is required; but if it should be light, then a soaking may be necessary. Plants in robust health, and well rooted, are not likely, so long as the drainage is perfect, to take injury from a liberal supply of water; but let the pots become waterlogged, or short of water for a few days, and the falling buds will soon reveal the consequences of neglect. With experienced cultivators this is not likely to happen; but, notwithstanding, it is just the thing that does happen with three-fourths of those who complain of failing buds.

Camellias, however, as you have lately shown, will grow in the open air in many places, and form glorious shrubs, but the flowers are so easily injured that sheltered situations must be selected for them. As far back as 1830 there were fine Camellias growing at Wortley Hall, near Sheffield, in the open border, the utmost protection they received being a mulching of leaf mould over the roots, and a mat of two to break the force of rough winds and severe frosts during the blooming season. However, these plants perished in Murphy's memorable winter, 1836-37, being killed to the ground. In the garden of the Royal Horticultural Society, at Chiswick, there used to be some handsome Camellias upon the north wall of what was called the experimental garden, but these perished some years ago, though I have many times seen them bloom very superbly. Camellias, too, used to bloom well every year against a north wall in Messrs. Chandler's nursery, in the Wandsworth Road.

The finest Camellia tree in England is that at Thames Bank, near Kingston. This, even thirty years ago, was a splendid bush, often producing upwards of a thousand blooms in a season. The kind is *C. reticulata*, and I have seen flowers upon it eight inches to nearly a foot in diameter. Few gardens have finer Camellias than Chatsworth. There they receive abundance of soft water in the growing season, and the plants are never exposed to the open air. One plant upon the conservatory wall of *C. reticulata* is a superb specimen, and when in bloom, is a sight worth seeing.

One fact connected with the cultivation of the Camellia must not be omitted, and it is this: it will not grow in soil from the limestone formation; like the Rhododendron and other American plants, it seems to abhor lime. In tough fibrous loam from the sandstone formation, taking the fine soil out, using it rough and making it as firm as possible in the pots, it will grow like a Willow; and the same may be said of it in such upland peat—poor as it is—as may be procured upon most parts of Sherwood Forest. This laid up for a few months

to rot and then broken up to the size of pigeons' eggs, and the fine soil taken away, is as good a soil as need be used for Camellias. Cleanliness, that is, a regular washing of the foliage, and a timely thinning of the blossom buds, are important items in reference to success. Many plants cast their buds more from the numerous quantity left on than from any inherent weakness in the plant. Therefore, always thin boldly, never leaving more than two buds upon each branchlet, and let those be of a size to give a succession of bloom for the longest time. Do this, and less will be heard of Camellia buds dropping.

B.

A REVISION OF THE GENUS DRACÆNA.

BY DR. REGEL.

(Continued from p. 567).

DRACÆNA GRIFFITHI (RGL.)

STEM half-shrubby, branching; scales at the lower joints of the stem probably soon deciduous. Leaves in partial whorls, lanceolate, acuminate, slightly undulated, gradually narrowed at the base into a channeled stalk from $\frac{1}{2}$ to $\frac{3}{4}$ of an inch long, with a rather conspicuous midrib, and marked with fine longitudinal veins, from $\frac{1}{2}$ to $1\frac{1}{2}$ inches broad, and from 4 to 7 inches long (including the stalk). Panicle terminal, shortly stalked, simple; branches reflexed and loosely racemose. Flowers solitary on slender stalks $\frac{1}{2}$ inch long and jointed near the base, the lower joint persistent, the upper one deciduous with the flower. Bracts scarious, scarcely as long as the lower joint. Corolla about three quarters of an inch long, with a slender cylindrical tube and linear divisions. Eastern Bengal.

I have seen the specimen gathered by Griffith and described by Hooker in No. 5,869 *Bot. Mag.* It is very like *D. surculosa* in habit, and has stems of the thickness of a goose-quill. Whether these are solitary or whether several issue from the rhizome is undetermined. The *D. ternifolia* of C. Koch (*Wochenschr.* 1867, page 238) appears to be identical with this species.

DRACÆNA THALIOIDES (MORR.).

Stem stout, simple, leafy from the base up, or from the middle up. Leaves in two rows, elongated-lanceolate, abruptly narrowed at the base into a wedge-shaped stalk from 4 to 9 inches long and very gradually attenuated at the point, with a rather conspicuous midrib which is prominent on the under-side, striated with veins, from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches broad, and from $\frac{3}{4}$ to $1\frac{1}{2}$ feet long, exclusive of the stalk. Upper leaves closely erect, patent; lower ones recurved at the point. Raceme terminal, simple or branching at the base. Flowers two or more together, on very short stalks or sessile, with a narrow lanceolate bract. Tube of the corolla white, slender, cylindrical, about half an inch long, longer than the bracts; divisions linear, patent or recurved, of a reddish colour on the outside, white within, as long as or longer than the tube. Tropical West Africa.

Synonym.—*Dracæna aubryana* (Fl. d. Serres, and Koch *Wochenschr.* 1867, p. 239).

DRACÆNA PHRYNOIDES (HOOK.).

A low under-shrub with a very short stem which has some scales at the base. Leaves ovate, rounded at the base or subcordate, acuminate, $\frac{2}{3}$ to 4 inches broad and 8 inches long, of a dark green marked with whitish spots, with a midrib which is prominent on the under-side and from 6 to 9 slightly prominent longitudinal nerves; stalk from $2\frac{1}{2}$ to 8 inches long, cylindrical, channeled on the upper part and sheathing at the base. Raceme terminal, capitula, with a short stalk. Flower-head sub-globose, about $1\frac{1}{2}$ inches in diameter, surrounded by broadly-ovate, abruptly acuminate, tawny, imbricated bracts. Flowers white, in clusters of several together; bracts tawny, ovate, as long as the tube of the corolla, which is thread-like and half an inch long. Divisions of the corolla oblong, patent, shorter than the tube. Found by Mann in Tropical Africa, near Fernando Po.

DRACÆNA SAPOSCHNIKOWII (RGL.).

Stem tree-like, simple at first, afterwards branching. Leaves crowded together at the top of the stem and at the ends of the branches, sessile, strap-shaped, sharply attenuated towards the point, flat, with a mid-rib which is inconspicuous on the

upper surface, but prominently convex beneath, striated with fine veins, of a full green colour, not variegated, covering the internodes of the stem with their clasping bases, from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches broad, and from $1\frac{1}{2}$ to $2\frac{1}{2}$ feet or more long, the upper ones very patent, the lower ones reflexed. Panicle terminal, with numerous divaricating branches; the branches and their sub-divisions being very patent and densely covered with flowers. Flowers on short pedicels, and arranged in fascicles of three to six flowers; fascicles scattered or collected in partial whorls, with scarious lanceolate-acute bracts somewhat shorter than the pedicels. Corolla scutellate, small, green or yellowish-green, three-tenths to four-tenths of an inch long, divided beyond the middle; divisions linear-oblong, erect. Filaments saffron-coloured, thickened, attenuate-filiform only at the apex; anthers yellow. Style about as long as the stamens. Native country unknown. I saw a specimen growing in the gardens at Saposchnikow.

DRACENA STENOPHYLLA (C. KOCH.)

Stem shrubby, often branching, with leaves from the base to the top, or from the middle to the top. Leaves narrowly linear-lanceolate, slightly undulated, somewhat membranous, covering the internodes of the stem with their partially-clasping bases, a quarter to three-fifths of an inch broad, and from 1 to $1\frac{1}{2}$ feet long, with a midrib which is inconspicuous on the upper surface and prominently convex beneath, striated with fine veins, and marked with yellowish longitudinal lines on a dark-green ground. Flowers unknown. Native country Africa or tropical Asia.

Synonym—*D. punctata* (Hort. Van Houtte).

DRACENA REFLEXA (LAM.)

Stem shrubby, branching, leafy towards the top. Leaves recurved, patent, linear-lanceolate, not covering the internodes with their half-clasping bases, with a midrib which is inconspicuous on the upper surface, and prominently convex beneath, striated with veins, $\frac{3}{4}$ to $1\frac{1}{2}$ inches broad, and from 5 to 8 inches long, not variegated at the margin. Panicle simple, sub-erect, terminal, or nearly so, with loosely racemose branches. Flowers solitary, or more rarely two or three together. Bracts scarious, shorter than the pedicels. Corolla $\frac{3}{4}$ of an inch long, greenish on the outside, white within, style longer than the stamens. East Indies and Madagascar.

Synonyms—*D. cernua* (Hook. et Roxb. fl. Ind.), *D. purpurea* (Hort. Berol.), *D. divaricata* (Willd. Herb.), *D. flexifolia* (Hort. Berol.), *D. timorensis* (Korth.); *Cordyline reflexa* (Fl. des Serres), *C. timorensis* (Pl. L. C.).

DRACENA CERNUA (JACQ.)

Margin of the leaves red. Panicle drooping. In other respects similar to the preceding. The Mauritius.

Synonym—*Cordyline cernua* (Fl. des Serres).

DRACENA RUMPHII (HOOK.)

Stem tree-like, robust, simple, short, with leaves only at the top. Leaves sessile, patent, recurved towards the extremity, linear-lanceolate, concealing the internodes of the stem with their clasping bases, flat, gradually attenuated into a long point, from 1 inch to $1\frac{1}{2}$ inches broad, and from $1\frac{1}{2}$ feet to $1\frac{1}{4}$ feet long, with a narrow transparent margin, and with a midrib, which is inconspicuous on the upper surface, and prominently convex and broad beneath. Panicle terminal, erect, compound, with racemose branches. Flowers in threes or fours. Bracts shorter than the pedicels. Corolla greenish-white, an inch or more long. Stamens as long as the style; filaments dilated towards the top and wrinkled. East Indies.

Synonyms—*Cordyline Rumphii* (Bot. Mag.), *D. Hookeriana* (C. Koch.), *D. angustifolia* (Korth.), *Cordyline Rumphii* (Fl. des Serres.)

(To be Continued.)

The Training of Hothouse Climbers.—If we spoil our hardy climbers by nailing them as rigidly against walls as the gamekeeper does his enemies, our indoor climbers fare, as a rule, no better. A decided improvement in the mode of training indoor climbers is shown in the Birmingham Botanic Garden, in letting loosely down the flowering shoots of such plants as the *Lapageria* and *Stephanotis*. Trained close to the roof as usual till just coming into flower, and then allowed to hang freely down in a natural manner so that their beauty may be seen, the effect is very good, much better than that obtained in the ordinary way.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Adiantum rubellum.—This singularly pretty fern deserves a place in every warm fernery, associated with the comparatively few coloured or variegated-leaved ferns we have. Just now its young fronds are peculiarly attractive, being of a crimson red, the older ones varying through brownish green to green. The plant gives a pleasant sparkle to other delicate ferns with which it is grouped.—H. V.

Oxalis rosea.—I was struck with the beauty of some pots of this charming plant, which I saw growing at Chiswick, a few days ago. Mr. Barron had many plants of it in thirty-two sized pots, in the house, and they would have proved useful for house decoration at South Kensington, but when transferred there, this Oxalis refused to flower, though at Chiswick it is literally covered with pretty rose-coloured blossoms. I presume, therefore, that it requires a clear, airy locality like Chiswick in which to flourish, and under these conditions it is certainly an attractive and useful pot plant. The plants which I saw had been raised from seed, and about two or three had been placed in a pot of the size I have mentioned.—R. D.

Clivia nobilis.—This is beautiful in the conservatory during February and March, when it comes into flower. It is a Clivia, but of a different colouring than this plant is by itself, the colour seems still more intense and striking when combined with other things. This really noble plant should have a conspicuous place in all conservatories, especially where planted in the natural style, which, sooner or later, must come to pass. It is easily grown in equal parts of sandy loam and peat with a sprinkling of sand and charcoal. Do not pot often, but feed it with a little manure water when growing. Give it a little shade, and let it have a little sun, and it will get along well. It will bloom in August or September. A plant here in a twelve-inch pot has thrown up eight fine spikes, averaging twelve blooms on each. It is surprising how long these flowers last before fading if kept from drip, and not in too high a temperature.—J. TAYLOR, Maegwynne, South Wales.

THE FRUIT GARDEN.

RUST ON GRAPES.

UPON my grapes last summer—an abundant and healthful crop—there appeared, to my sad surprise, the disfigurement of rust. Of some two hundred bunches, nearly one-half became unsightly and distasteful. There was no remedy. What was the cause? Some said the vines had been overcropped; and they certainly had yielded for many summers a very ample fruitage. Some said they had been robbed of atmospheric aliment by plants growing beneath them; and I had, undoubtedly, been constrained by a circumstance, not unknown to enthusiastic gardeners—that is, want of room—to crowd my viney too much. Some said that the grapes had been rubbed in thinning, or touched by persons walking beneath; and every one who has thinned grapes knows how difficult it is only to touch that which we take, and every one who is six feet four inches in height has occasionally had more berries than blessings upon his head, when walking in a low viney. And some said that the grapes had been syringed with hard water; and, when I remembered that, in a season of drought not long before, there had been a tremendous duel between my gardener and laundry-maid on the subject of soft-water, this suggestion did not seem improbable. And so the origin of the rust, like a good many other origins, remained a mystery.

Some three weeks ago the plague-spot reappeared, only on a few bunches, and on a few grapes in each bunch, but to my great disappointment and perplexity. Again came the question, What is the cause? And I believe that I have found the answer in my good friend, William Thomson's "Practical Treatise on the Grape Vine," under a paragraph devoted to the subject. "I am certain," he says, "that the most fertile source of rust is the application of sulphur to the pipes or fum about the time the grapes come into bloom." I remembered, as I read, that in the spring of last year, the hot-water pipes in my viney had received an extra coating of sulphur until they were as yellow as the legs of a Blue-coat boy, and that rust, for the first time, had subsequently appeared on my grapes; and I rushed off to my garden to remove at once certain plates, filled with bromstone powder, which had been placed underneath the vines. Since that removal the rust has not extended, and but little harm is done. And I have just had a striking confirmation of Mr. Thomson's observations, while conversing with one of his old pupils, Mr. Lyon, who is now head-gardener to my neighbour, Lord Ossington, the late Speaker of the House of Commons. I was speaking of sulphur as the cause of rust, when he remarked that there was an exceptional case in one of his vineries near us, for he had noticed slight traces of rust upon some grapes where no sulphur had been used. Then he suddenly remembered that beneath the very vine referred to, there was growing a plant of rose Maréchal Niel, which had been affected by mildew, and liberally dusted with sulphur.

I am aware that many readers of THE GARDEN know much more of this subject than I, but I have written for those who know less; and some of these, hearing for the first time, that no sulphur should be applied before grapes are stoning, may profit from the experience of

S. REYNOLDS HOLE.

OVER-CROPPING FRUIT TREES.

THERE is more permanent injury done by over-cropping fruit trees, especially in the case of vines and stone fruits, than is generally supposed. Sometimes a voice is raised against the evils of this practice; but generally without avail. There is something seductive and gratifying to one's vanity in seeing a tree carrying what is called a "splendid crop," and in hearing the praise that is often lavished on a man for overloading his trees, when in reality he ought to be censured for his short-sightedness. We are all very apt to think too much of the present and neglect the future. Overwork is bad both to animal and vegetable organizations, and even an iron constitution will, in time, break down under it. Fruit trees when persistently over-cropped become so exhausted and debilitated that they fall an easy prey to insects, which still further reduce the vital principle, and render their recovery almost hopeless. I am convinced many peach and apricot trees, both in houses and on walls, have come to a premature end by over-cropping alone; while some other cause has often been assigned for the loss.

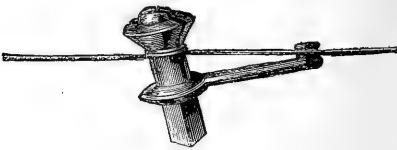

It is an old saying, "our enemies ought to thin our fruit," meaning thereby, that the thinning would be effectually done. It requires a vast amount of resolution to thin sufficiently, and especially do I find it so this season in the orchard house, where I have never seen the fruit set thicker, whilst on the walls the crop is thin. One is too apt to overload the trees under glass in a season like the present to compensate for the thin crop out of doors; but this system of striking balances is a most unsound one. Mulching and frequent soakings of sewage or liquid manure are very useful in enabling a tree that is heavily cropped to bring the fruit to perfection with a minimum amount of loss to its permanent vigour and strength. It is much better to render assistance in this way when it is wanted than to dig manure into the borders; in fact, I believe the digging of fruit tree borders to be bad in principle, as fruit trees do best in a firm soil. It is only in places where the subsoil is especially suited for fruit culture that digging and cropping close up to them can be done with impunity.

E. HOBDAY.

Ground Vines.—The simplest way of making glass available to produce first-class grapes is the adoption of ground vines. In the first instance of using these, a trench was dug; the trench was lined with slates, and was covered with a small glass ridge. The vine was planted in common soil at one end outside the trench, and was trained along the centre of the trench under the glass, the bunches being allowed to hang in the trench, and receiving heat direct from the sun overhead, and indirectly by radiation from the slates. This answered very well; but experience proved that the simplicity of this contrivance might be simplified. The glass ridge was placed on the level ground, on a row of bricks placed a few inches apart to afford ventilation, and with slates or tiles laid on the ground inside, so that now the bunches lay upon the slates, and were there subjected to greater heat than when they hung in the trench, and the consequence was, the berries grew to a greater size and ripened more perfectly. There is no mystery about ground vines; any carpenter can make them, any amateur, even a mere beginner, manage them; and they are so far useful for the cultivation of grapes, that by their aid bunches fit for exhibition may be grown in them without difficulty. The chief secret of their efficiency is their power of absorbing and retaining a greater amount of sun heat than is possible for either walls or exposed soil. Currents of air which quickly cool the common soil, are excluded by the glass, which also tends to check radiation, so that within the ground viney a better climate is secured than can be in any way obtained without the aid of glass. These vines are made in various ways and sizes. Some are adapted to accommodate two vines side by side, others for single vines only. The size found most suitable for one vine is thirty inches wide, sixteen inches from ground line to ridge, twenty inches slope of roof. For two vines, forty-two inches wide, twenty inches deep, twenty-eight inches slope of roof. The length of such vines may be indefinite, but for convenience sake they are usually made in seven feet lengths, and as the vines extend in length, additional lengths of glass frames are added; and of course the vines are always kept to single rods, closely spurred in. To appropriate these simple structures to the purpose they are intended for is easy enough. The ground is marked out, and bricks are laid a few inches apart for the frames to rest upon. The bricks keep the frames from touching the ground, which tends to preserve them from decay, and they serve at the same time to insure perfect ventilation, so that there is never any occasion for this purpose to move any portion of the glass. As for the vine, that is planted at one end, in a mixture of good loam and broken plaster or old mortar, with a little manure. A rich soil is not desirable, but it is desirable the position should be dry and the soil light; conditions which promote a perfect ripening of the wood in the autumn. The slates are simply laid on the common soil, and the vine is kept in its place on the slates by means of a few pegs.—*Floral World.*

THE THOMERY WIRE-STRAINER.

This simple little raidisseur, which I brought from Thomery several years ago, is now much used in some places and successfully. In Mr. Mault's garden, at Stoke, I saw a good deal of very neat trellising effected by its aid. It would be an improvement to cast it with two arms instead of one. In this way it would be less

liable to break the wire than it now is in inexperienced hands. In France they have no trouble in wiring walls well with it, with little or no breakage. To save the wire from breaking over the sharp edge of the little implement, it is well to put a few coils of wire round the drum before winding it tight.

W. R.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Trees Exceptionally Fertile.—I have a young peach tree, only three years old, with twelve dozen of fruit on it. Shall I leave them all? or remove some, and how many?—AGNES.—[Remove seven or eight dozen of the fruit. There is nothing so disastrous as over-cropping; it cripples the trees for years. The temptation is great, but every tree must bear its proper burden.]

Wall Trees and the Garden Engine.—The garden engine is a good servant at the right time, but a most mischievous tool at another. A neighbour with such a fence against their wall trees as to rend delicate leaves, smoulder, bruise tender fruit, and even fracture the young shoots. A shower is a good thing, but a waterspot means destruction. A word to the wise is enough.—D. T. F.

Wallich and Orchard Houses.—See one of your correspondents, writing from Lochrigghead, denounces garden walls (p. 537). I know not exactly where this is, but assume it to be some unpleasant part of Scotland where a sight of the sun is a pleasure, but a misfortune. The author, however, is right in his opinion of garden walls for the midland and southern parts of Great Britain and Ireland, than we have to denounce him for resorting to the orchard house in a climate where good fruit culture against walls is impossible. It is simply untrue to say that the best fruit may not be grown on properly-managed walls.—H. V.

Forwarding Strawberries.—Place some of Rendle's protectors over a row or two of Black Prince and Keens' Seedling Strawberries in the open air, and gather them in, but do not expose them to the strong sun in consequence. Or young plants may be planted in boxes in the autumn in the shade of one of the large four light frames, and these now placed over them. As the crop is all that is wanted, the plants may be packed closely together, and the quantity of fruit that may thus be reaped from a given space may really be called prodigious. The fruit is not only forwarded, but its quality is improved, and it is safe from birds and vermin, unless, indeed, the mice or rats, attracted by the unseasonable colour, find a way inside, as they are almost sure to try to do.

The Edible Passion-Flower.—Whatever the value of jam or compote from the flower, it is surely not to be despised. I have, however, come to the conclusion that, though these two plants are noble ornaments both in flower and fruit in the warm stove, yet that, as fruits, they are utterly inferior to the small Passiflora edulis, which, though not growing bigger than a large plum, fruits abundantly. It grows freely in any cold greenhouse conservatory, or orchard house, is sown with a fruit in the axil of every shining leaf, hanging down, and easily gathered after all blossoms-bar. It has a really distinct and deliciously acidulous flavour, and well merits a regular place in every garden where indoor fruits are grown. Of all the neglected greenhouse or hothouse fruits I know, it is the best.—H. V.

Best Dessert Apples.—Will you kindly tell me what are considered the best of the dessert apples now in our gardens, limiting the selection to about twenty?—Z.—[The following are recommended by an experienced grower, but no doubt tastes will differ, and we shall be glad if correspondents from different parts of the country will add to the list. The following are selected from White Pippin, early Red Marnell, Red Astrachan, Early Strasburg, Irish Orange, Summer Golden Pippin, Kerr's Pippin, Margil, Ribston Pippin, Cox's Orange Pippin, Mannington's Pearmain, Golden Drop (Co'e's), Ashmead's Kernel, Old Nonpareil, Reinette Van Mons, Stockhouse Russet, Kedleston Pippin, Golden Harvey, Winter Pease Apple, Sturmer Pippin, Calville Blanche, Court Pudding, Adam's Pearmain, and Court of Wicke.]

The French Paradise Stock.—Is the French Paradise Stock really quite hardy? Englishmen say it is a very soft—Cormier, V.—[The French Paradise stock is hardy in all parts of Britain. As respects its behaviour in a colder country than ours, the following communication, sent in 1859 to a contemporary by Mr. Such, of South Amboy, New Jersey, speaks sufficiently clear:—"In my garden I have on this stock many little bush-like apple trees that have endured the greatest extremes of heat and of cold. About four winters ago the thermometer fell to 20° below zero, and last summer the heat was intense, reaching 100°. In spite of all the care I could take, my little bushes were in perfect health. The Doucain stock is also thoroughly hardy. There is now here a small orchard of apples on this stock, planted more than fifteen years ago, all of which are in full vigour. My trees on the Paradise are very large, long currant bushes; those on the Doucain are from ten to fifteen feet through." The Paradise thrives best on a clay soil. In planting trees on this, the part where grain and stock should never be buried, the roots of the tree will be sent into the soil, and there grow firmly enough for an orchard specimen. I have found in several cases it promises very well indeed on stiff clay soil in Middlesex, both as horizontal cordons, and as small pyramids.]

PUBLIC GARDENS.

THE CENTRAL PARK, NEW YORK.

(Continued from p. 545.)

THE water in the Park is very well managed; but under this head is not included the large reservoirs, with which the gardeners, or landscape-gardeners, have nothing to do. In various parts the margins of the water present a very picturesque appearance, from the cropping forth of the natural rock.

One of the most pleasing features in this park is a wild, tangled wood, called the Ramble. This pleasant spot, to many the greatest attraction the park contains, lies upon the southern slope of the rocky ledge that occupies the middle of the park, sloping gradually towards the east. It is estimated to contain about sixty-three acres, and, although it has several open spaces of lawn, it is for the most part, quite thickly planted with trees and shrubbery, and laid out with a multitude of irregular and interlacing walks, arranged without any definite plan. It was once an unsightly mass of particularly barren rock, on which even mosses and lichens refused to grow; the soil thinly spread between the ledges was too poor to support any but the toughest and least graceful shrubs, while along its centre there ran a bit of boggy marsh that held the drainage of the higher portion until it could leak down into the still lower valley, or until it should be dried up under the heat of

View of portion of Lake in Central Park, New York.

the August suns. To-day no rock is seen but such as is needed for picturesque variety; the rest is covered with earth or overlaid so thickly with honeysuckle, wild grape, trumpet-creeper, or Wistaria, that its presence is not suspected by the passer by. From April to September the Ramble is filled with the delightful perfume of these honeysuckles, while to these is added, in June, July, and August, the even more delicate odour of the swamp Magnolia (*M. glauca*).

The design in planting the Ramble has been to give it, if possible, the delicate flavour of wildness, so hard to seize and imprison when civilization has once put it to flight. Therefore, an effort has been made to bring into these bounds as many of the wood flowers and flowering shrubs, the native growths of forests, as would thrive here—foreign flowers and imported shrubs being put in places more evidently artificial. The success has been considerable, and every year adds something to the list; so that already the city boy or girl may find here the earliest anemones, hepaticas, blood-roots, adders'-tongues, and columbines. We have seldom seen a place more suitable for the naturalization of British and European wild flowers.

The Central Park contains the essentials for the noblest rock-gardens ever seen. We have never anywhere else seen in a garden so many large picturesque and varied outcroppings of rock, scarcely one of which is yet planted with its appropriate ornaments. No such opportunity elsewhere exists for the natural culture, so to speak, of alpine and the more beautiful herbaceous plants.

In part of the park, the soil in the long clefts of a mass of the gneiss rock is filled with the native cactus,

commonly called the prickly-pear, which grows so thickly over the rocks and cliffs in New Jersey, along the Hudson River shores. It has thick, fleshy leaves, blunt oval in shape, set all over with small bunches of very fine sharp thorns, so easily detached that it is impossible to touch the leaf without getting some of them into the flesh. The flowers, which, in the season, are very numerous, are extremely delicate and pretty, being of a bright canary yellow, and having a tropical appearance that increases the pleasure of coming upon them in one's walk. Whether they were found growing wild on these rocks when the park was first taken in hand, we do not know, but here they are to-day, mingling their large, gauze-like, yellow stars with the profuse bloom of the Portulaca, and, no doubt, deceiving many with the belief that they are some rare species of cactus from foreign parts, set out here to bloom for a summer, and to be tenderly nursed and housed during the coming winter.

The designers deserve great praise for having so carefully preserved these beautiful rocks, which, if properly planted, must one day become the finest series of rock-gardens in existence. For our illustrations of the Central Park (with the exception of our plan, now being engraved from the large

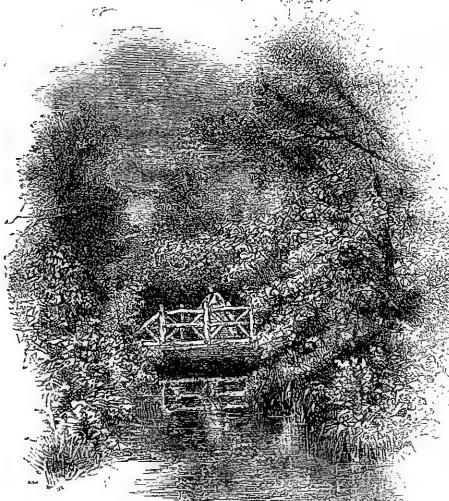

Armill of Lake in Central Park, New York.

and admirable reports issued yearly by the Commissioners), we are indebted to "A Description of the New York Central Park," published by Huntington & Co., of New York, a capital guide to the park, and containing many just remarks on it. It is evidently written by some one who has looked a little below the surface into some of the more important questions concerning public gardens, as the following extract on sculpture therein will show:—

"There is no one among the many difficult subjects almost daily presented to the park authorities for consideration more difficult than the limit to be placed to the admission of sculpture into the park. To persons who have not given much thought to the matter it may seem that the easiest, and also the wisest, thing the Commissioners could do, would be to take every piece of statuary that is offered them, that has any merit whatever, and find a place for it somewhere in the park. But to this the Commissioners very properly, as it appears to us, demur. In the first place they do not want any statuary at all, unless it is the best that can be produced. Looking upon the park as they do, not merely as a place of amusement, but as a place of education, they have always considered it a matter of conscience to exclude everything that falls short of the standard they have proposed to themselves. It may be very difficult to get good statuary; they may have to wait a long time for it; but they cannot see in either of these suppositions any argument for permitting

the precedent of placing second-rate or indifferent works of art in the park until the good works shall arrive. Thus far there has not been a single piece of statuary presented to the park and placed in it that it is at all desirable to have there. The statue of 'Commerce,' presented in 1863, by Stephen B. Guion, Esq., a native of New York long resident in Liverpool, is a mere commonplace emblematic figure, such as are all the time being produced in French studios, but which have very little meaning or interest for the great mass of people, and for artists none at all of either. Yet, what are the Commissioners to do? A much respected gentleman, animated by a praiseworthy desire to do something for the adornment of his native city, orders this statue from Fesquet—a clever French statuary—and in the quietest, most modest way possible, presents it to the park, without imposing any conditions, without asking for any particular site, without even attaching his name to the gift. It certainly is very much to be wished that the respected donor had given us something else; that he had ordered, for instance, Quincy Ward to put his 'Indian Hunter' into bronze, or had given a commission to Story, or to Brown, or to Launt Thompson; but, as he did not do any of these things, we must make the most of the gift he has presented.

"It will be seen, then, that the whole subject of sculpture in the Park is beset with difficulties, and that the Commissioners have more than any mere personal interests, whether of their own or of

View in Ramble, Central Park, New York.

other people, to consult. For, apart from the question of good or bad sculpture, is the problem how to limit its introduction to such a point that it shall not detract from the apparent size of the park; a most serious consideration. Many of our readers must have had the opportunity of observing how quickly the apparent size of a garden is reduced by the introduction of statuary, which it was at one time in the fashion to use much more freely than has been done since the 'natural style' of gardening came into vogue. Not only is the area of the garden or lawn so ornamented diminished to the eye, but walks and roads along which statuary are placed are visibly shortened. Both these facts are no less facts for being optical delusions, which are the result of a well-known natural law. They are delusions constantly taken into account in decorative design, and cannot safely be neglected. Their bearing on the question of the park is plain. The area of the park, however large it may sound when stated to the ear, or however it may seem on paper, is in proportion to the population that is to use it, by no means so large as it seems to the superficial observer. And this process must continue; the park growing sensibly smaller and smaller with every conspicuous object that is placed in it, giving the eye a means of measurement, until, at length, its real dimensions cannot any longer be concealed.

"The great danger is, lest the park should come to be looked upon merely as a place wherein are collected a large number of curious

and rare, or pretty things, which would, it is true, be a recommendation to a museum, or to a garden of plants or animals, but not proper to a park. A park is a place of rest and recreation for mind and body; and while nature soothes and tranquillizes the mind, and thus gives the body that repose it needs, a number of petty artificial

Cove and Outcropping Rocks in Central Park, New-York.

objects, merely curios or pleasing, distracts the thoughts and frets the nerves. But we plead for the preservation, as far as possible, of largeness and simplicity, for the greatest amount of unobstructed lawn, for trees, and shrubbery, and flowers; for lakes and streams; in short, for as much of nature as we can get for money, and for a very little art, and that only of the choicest and best."

(To be continued.)

THE LIBRARY.

HORNBY MILLS.*

One of the charmingly and spiritedly written books of Mr. Henry Kingsley, particularly interesting to lovers of gardening from that capital story, "Hornby Mills Garden," with which the book opens. The following description of Hornby Mills garden will suffice to show the character of the work:—

"We used to say, and I believe now, that the house had been a 'religious house,' because of the great fish-ponds which surrounded it. The fact that it lay in a hole, rather below the level of the neighbouring ditches, seems to confirm that theory, though the house itself was scarce a century old. There was a rookery, in elms planted certainly at the Restoration, and the garden invaded their shadows, until nothing would bloom in the shade except primroses, which grew white and flesh-colour in the darkness; a wilderness of wild hyacinths, shining in May like another heaven; wood anemones, wood sorrel; the blue pasque anemone. And as the summer heat settled down, and made the summer beds blaze into a scarlet mass of geraniums, and infinite varieties of other beautiful flowers, the golden Tutsan St. John's wort lit up the darkness of the shrubbery. Waterer in those days was a comparatively young man at Bagshot, and azaleas were hardly invented. . . .

"A busy brisk house, until you opened a gate in a wall, and passed into the odorous silence and heat of the garden; here was a stillness scarcely disturbed by the cawing of the rocks. This was the ladies' quarter. This was the life's amusement of the two

"Hornby Mills, and other Stories." By Henry Kingsley. In Two Volumes. London: Tinsley Brothers.

maiden sisters of the house, Aunt Bridget and Aunt Hester. On this garden they lavished all their own perfect refinement; to this garden I wish to call your attention, as a type of English garden now almost extinct; and before I have finished with it I think you will allow that I was right in speaking of the general *mélange* of this particular country house. . . .

"Extravagant as all the other arrangements in the house were, there was no extravagance in the garden. There was no gardener, for instance, worth calling so, only an old man kept on by the week, with sometimes a labourer to help him; all the direction, and no inconsiderable part of the work, was done by those two charming refined maiden ladies. A rich acquaintance of ours, Mr. Dash, has made me laugh to day, by telling me of a letter he had received from a gardener who had advertised for a situation. This gentleman gardener said "that he did not like the tone of Mr. Dash's letter, and thought the place would not suit him." Now the old garden I speak of is not much smaller than my friend Dash's garden, and, I think, infinitely more beautiful. . . .

"There were but few sorts of chrysanthemums cultivated then, and those of inferior sorts; but such as there were, were gay and gaudy enough. In an open winter, their yellow had scarcely become tinged with the delicate rose-pink which marks their decay, when the Christmas rose (*Helleborus niger*) began to blaze out in white patches of large flowers at regular intervals about the otherwise empty beds; and before they were gone the whole map of the garden was marked out by brilliant golden lines. The little aconite, planted thickly, close under the box-edging, showed the shape of each parterre in a hard golden line. The garden, beautiful at all times, was seldom more beautiful than at the beginning of February, when the aconite and hellebore were in flower; but before the yellow bands and the brilliant white patches had begun to fade, the colour of the garden had changed, the hepaticas—crimson and blue alternately, and giving a general effect of purple, planted closely just inside the aconites—marked out the beds once more with a new colour, and held on nearly till March.

"But by this time nature, under the guidance of our two ladies, had begun to rebel against formalism, and there was no more "ribbon gardening." After the hepaticas, the flower borders began to possess a new interest, and your admiration of "bands of colour" became lost in the contemplation of individual beauty. From the centre of each bed, white, yellow, and purple, arose a corona of crocuses, about two feet in diameter, matted thickly together, and the whole garden shone like fire, relieved by the moonlight effect of the snowdrops. Almost with them came patches of the pale pink dog-toothed violet, and the white dog-toothed violet with the purple eye (which last is, with very few exceptions, one of the most beautiful flowers in nature, and the roots cost sixpence apiece). None of the above-mentioned roots were ever moved; they cost nothing whatever in maintaining; and, once planted, would flourish for ever, being far best left alone.

"I say that one flower succeeded the other in this wonderful garden: but the truth is there was no break. The crocuses were not fairly done, and the dog-toothed violets not half done, when a still more fantastic piece of colour trickery was ready for your eye. A ring arose round the fading crocuses, cunningly alternated in every other bed. In the one bed this ring was made up of cream-colour, pink, white, and purple all commingled; in the next, of a vivid intense scarlet, more vivid than most geraniums, nearly, or quite, equaling the brightest tropaeolum; and these bands were about foot broad. What were these flowers? These were the anemones, nodding their heads to one another in the March wind, and seeming to congratulate one another on the coming spring. We must now leave the principal borders for a while, and go down to certain sloping beds near the gold-fish pond, in front of the moss-house, which were never disturbed by the gardener's fork, and which are quite ready for us now.

"The first thing which struck the eye here, in this quiet sheltered spot, sloping south, were bright patches of the common primrose, shining among the ferns and other green vegetation like groups of stars; until you had ceased looking at them, you could not take in the fact that there was a haze of blue violets mingled through them, which was loading the air with perfume. Primulas, too, of every wonderful variety were here. All the beautiful polyanthus, some running almost into dull purple, others almost into fiery scarlet. The pale and coloured primroses, the commoner auricula, the sturdy oxlip, the delicate scented cowslip, even the rare pale blue bird's-eye primrose. There were orchises from the meadow trenches, sombre-coloured frillarias from the Oxford meadows, blue pasque anemones; every flower which spoke of spring, of budding leaves, of singing-birds, of the renewed hopes and plans which always come to us at that time, year after year, until the eternal spring buds forth which never turns into summer; all these were collected here in that

quiet sunny border beside the fish-pond, and close to the church-yard."

"Viator here begged Horticulturis not to be sentimental.

"Every flower in that spring border," Horticulturis said obstinately, "spoke of spring-time, and youth, and hope, and love-making. And of all the beds in the garden, those two quiet melancholy old maids—quiet and melancholy amidst all the growing extravagance and profusion around them—loved that secluded border the best, and tended it most carefully. They may have walked out among the blooming meadow flowers, not alone, once on a time, and that may have been the reason why they bent their spare and weakening bodies, and their faces, which grew more anxious year by year, as the reckless riot went on, so lovingly over them now.

"The wonderful freshness and beauty of our English spring flowers are scarcely beaten by any class of flowers in the world," he continued, "any more than a good example of our English spring is to be rivalled, either for weather or for colouring, elsewhere. The Australian spring, when nature expresses herself in a sudden efflorescence of delicate, hitherto unnamed, orchises; when the earth is all flowers, and the air like maddening champagne, that is a season which goes near to satisfy your soul; but an English spring is finer. The "luxury" of the English spring vegetation is, I think you will find, unsurpassed in the world. I have had a glimpse of the tropics, and you may see the tropics at Sydenham and at Kew pretty well; have they anything to offer you like an acre or so of wild blue hyacinths in the middle of May?"

"Have you anything more to tell me about this wonderful garden?"

"A good deal. I could put more into your head about gardening than ever was there before; but you won't let me do it in my own way. Once more; is the garden we saw to day, a labyrinth of badly-conceived and worse-executed Chinese patterns, with a Scotch gardener to show you over it, and point out its barbarisms—is that a garden at all?"

"A sort of one."

"A sort of one, exactly. But those two old ladies of mine had flowers in their borders all the year round, whereas my lord's beds are utterly empty six months in the year. Can you gather that?" "Yes."

"Well, when the time came their garden was just as brilliant as my lord's, and ten times more artistic. Time would fail me were I to attempt to tell you of the beauty of these flower-beds in summer; of the mass of colour, confused but always artistic, which grew brighter as the summer went on, and which lay round the towering spikes of the hollyhocks, the various lilies and bee larkspurs (the Delphinium formosum, the most splendid of our perennials, unless the new blue columbine of last year, which I have not yet seen, is destined to beat it, was not invented then). These hollyhocks and bee larkspurs were insignificant-looking things, just outside the anemones, if you will do me the favour to remember; not obscuring them in the least till they were out of flower, and then shooting up, and hiding the untidy crocus grass, and the seedy-looking foliage of the anemones, until they in their turn died down with the first frosts of autumn.

"So much," continued Horticulturis, "for the most perfect and well-arranged garden I have ever seen, and what is more, the cheapest. Let me recapitulate for a moment. The centre of each bed was filled in an oval or square of two feet, more or less, with thickly-planted crocuses; outside this, a ring of anemones; outside this again, a ring of hollyhocks and delphinia; then a bare space, of say of four feet, to receive the summer flowers. Then the hepaticas, a hedge of ivy-shaped leaves in summer, for a few weeks in early spring a blaze of crimson and purple; then the closely-planted aconites, and then the box. Such was the garden. I can describe the colour, but the hot rich scent of it is beyond me. The recollection of it makes me faint. It was the sweetest smelling garden I was ever in."

"Was?" said the unsentimental Viator.

"Yes. It is gone now. It was the most cheap and the prettiest garden of its pretensions I ever saw; but it is gone. Part of the old house is left, and a well-to-do man lives in it. But he has laid three quarters of it down in turf, because he says, much as he likes flowers, that he can't afford them. But Aunt Bridget and Aunt Hester never spent one half on their glorious garden which he does on his formal, and somewhat ugly (if flowers could be ugly), rows of calceolarias and scarlet geraniums. Now, in July, instead of the eye wandering from one curious piece of beauty to another, it loses itself, and gets thoroughly Cockneyed in running along mere bands of colour."

"All the old perennials eradicated?" asked Viator.

"Very nearly. Nature occasionally reasserts herself, to the great disgust of his gardener. Some of the old tulips still insist on

peering up through the new turfed ground, to be nipped off by the new mowing machine. Impudent crocuses still appear in the middle of the beds. The dear old hepaticas still hope to be forgotten by the new Cockney gardener, and modestly thrust themselves up in his absence (for he never is in the flower garden before May) and appeal to his more highly educated master. He *pleads* for them, but what pleading is of any avail against the spite of a doctrinaire new broom?"

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from p. 596.)

GROUP 2.—CROWN GRAFTING.

GENERAL DIRECTIONS.—This method is suitable to a large number of trees and shrubs of various kinds. It is practised in spring, as soon as the bark is easily separated from the alburnum, but the precaution should be observed of preparing the stocks beforehand, and heading them down three or four weeks before grafting takes place. Formerly this operation was very often performed in autumn, several months before the usual time of grafting. When inserting the scions, the cuts, which have been more or less cicatrised, should be freshened with the pruning-knife. The scion branches are cut during winter, before the sap begins to flow, and placed in soil or sand, either in a cellar or on the north side of a wall, in a vertical or a horizontal position, and either half or entirely buried; the essential point is to keep them from vegetating, and to see that the bark does not dry up. The scions are pieces of branches from two inches to five inches long. The upper half should have two or three eyes; the lower half is cut with a flat sloping splice-cut, which should begin opposite to an eye, and end in a thin point. It should be so cut as to contain no pith, which would rather interfere with the process of cohesion, and on the whole should be of no great thickness. A small notch or shoulder cut in the upper part, will serve to rest the scion better on the stock.

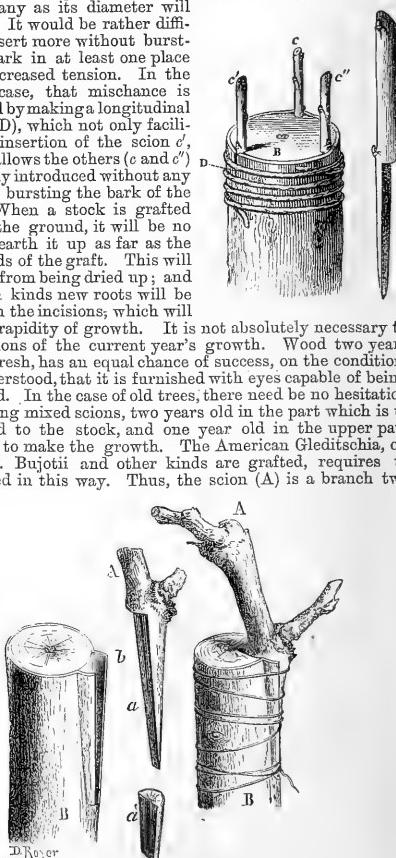

The scion is inserted into the top of the stock between the bark and the wood, the point being generally cut on both sides

to facilitate its entrance; some operators, however, content themselves with moistening the point with their lips. A small implement of wood or ivory is usually employed in preparing a place for the insertion of the scion. It has a long sloping point, which is introduced between the bark and the alburnum and on being withdrawn, the end of the scion is slipped into the opening. When this precaution is taken, there is no fear of breaking slender scions nor of bursting the bark; however, the simple pressure of the hand will often suffice to fix the scion under the bark without previously raising it. The introduction of the scion is in most cases facilitated by the circulation of the sap which separates the bark from the alburnum. However it may happen that the scions of large size will threaten to burst the tissues; in that case the best thing to do is to make a longitudinal cut in the bark with the grafting-knife at the moment of inserting the scion. The thicker the stock is, the greater the number of scions

which may be placed upon it; however, to render the cohesion more complete, there should be a distance between them of at least two inches. A bandage, which should not be too tight, nor compress the bark too much, is necessary after the insertion of the scions. Grafting-wax is applied to the cuts, and to the bark of the stock where it covers the scions, in order to prevent rents. The adhering of the wax is facilitated by wiping off the sap which oozes from the cuts. Our illustration

represents the head of a stock (which has been grafted, either by crown-grafting, or cleft-grafting, or inlaying, or veneering) bandaged and covered with grafting-wax. The wax is spread over the cut (A) on the head of the stock, where a branch has been removed (B), where the scion and stock are joined (I), and on the top of the shortened scion (O). The terminal bud (U) is not covered, nor the bud (Y) imbedded in the incision. Crown-grafting is, so to speak, indispensable in the case of large trees, on which a great number of scions may be grafted in consideration of the amount of nourishment furnished by the roots.

ORDINARY CROWN-GRAFTING.—In the stock (B) which has been cut to the quick, we insert three scions (*c*, *c'*, *c''*), which are as many as its diameter will allow of. It would be rather difficult to insert more without bursting the bark in at least one place by the increased tension. In the present case, that mischance is prevented by making a longitudinal incision (D), which not only facilitates the insertion of the scion *c*', but also allows the others (*c* and *c''*) *d* to be easily introduced without any danger of bursting the bark of the stock. When a stock is grafted close to the ground, it will be no harm to earth it up as far as the upper buds of the graft. This will secure it from being dried up; and in certain kinds new roots will be formed on the incisions, which will promote rapidity of growth. It is not absolutely necessary to select scions of the current year's growth. Wood two years old, but fresh, has an equal chance of success, on the condition, be it understood, that it is furnished with eyes capable of being developed. In the case of old trees, there need be no hesitation in selecting mixed scions, two years old in the part which is to be united to the stock, and one year old in the upper part which is to make the growth. The American Gleditschia, on which G. Bujotin and other kinds are grafted, requires to be treated in this way. Thus, the scion (A) is a branch two

years old, bearing two shoots of the current year cut down to the length of an inch or so. A sloping cut (*a*) is made in the old wood, of which a section is given at *a'*. It is then placed on the stock (B), in which a simple incision (*b*) has been made. It will be necessary to raise the bark with the spatula of the grafting-knife, or some such implement, in consequence of the size of the scion and the want of elasticity in the bark of the Gleditschia.

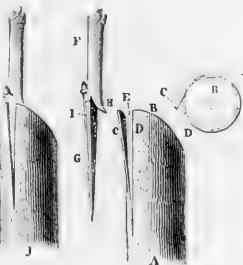

IMPROVED CROWN-GRAFTING.—This method differs from the preceding in two essential points.—1. The stock (A) being cut obliquely (as at B), the scion (F) is inserted on the top, with a tongue cut at an acute angle, and which fits accurately on the

slope of the stock. 2. An incision must be made in the stock, and the bark raised with the spatula on one side only (C). The scion is then slipped in, so that the fresh cut on the inside may come into contact with the albumen (E), and the back (G) be covered by the lip (C). The chances of success are increased by removing a small strip of bark (I) on the side of the scion, corresponding to the lip (D) on the stock, which will overlap it. At (J) the work is shown completed before the application of the bandage and the grafting wax. The section (B) of the stock exhibits the lip or portion of bark (C), which is raised from the wood, and the portion (D) which is not raised. These little alterations, which have been suggested by reflection and practice, and which are susceptible of great variation, have for their object the multiplication of points of contact in order to accelerate the cohesion of the graft. Professor Du Breuil has invented several of these improvements and recommends them in his works. In the department of Isère, where grafting of the walnut is more practised than anywhere else, M.

Chaix, of Biviers, has for a long time used the modified method of crown-grafting which we have just described. He cuts the stock in a sloping direction, so that the oozing sap may not obstruct the cohesion of the graft. An angular notch is made in the scion, which fits on the top of the stock, and the face of the longitudinal cut is made even to correspond with the surface of the stock where the bark is raised. The bark, it may be observed, is raised on one side only. In order to preserve the graft from the effects of heat and cold, he covers the cuts with clay, he then surrounds the graft with a band of bark four inches wide. In this way he operates on stocks thirty years old, and vouches for the success of the method.

TREATMENT AFTER CROWN-GRAFTING. — This is limited to—1, keeping an eye on the bandage, loosening it if it becomes too tight, and renewing it if the cohesion is not perfect; 2, tying up the young shoots on rods or on a stake taller than the graft; and 3, removing any shoots or buds that may appear on the stock—*C. Ballet*

(To be continued.)

NOTES OF THE WEEK.

— At Ribchester, a boy, aged twelve, named Leeming, was poisoned the other day through eating monkshood.

— About 2,000 miles of irrigating canals have been projected in California, which, it is said, will protect ten million acres of land from drought.

— REPORTS from America describe the forest fires there as extensive and terrific in character, both in New York State and Pennsylvania.

— In consequence of the heavy rains of the past month, herbaceous plants round London are very luxuriant, and promise abundant and vigorous bloom. The kinds now in flower are unusually fine.

— A new yellow flowered Columbine (*Aquilegia aurea*) is now in bloom at the Hale Farm Nurseries, Tottenham. In point of merit it is scarcely equal to the finely coloured flowers of many other species, but it is nevertheless quite distinct, and a really very interesting plant.

— THOSE who are not aware of the beautiful effect of good edgings of Irish Ivy, would do well to look at those at the east side of the avenue gardens in the Regent's Park, which are now of the loveliest and richest green imaginable.

— PALM oil has become one of the most important articles of commerce from the west coast of Africa, especially to this country. In the year 1808, we received 200 tons of palm oil from Africa; in 1827, the quantity had increased to 4,700 tons. Last year, 51,087 tons, valued at £1,789,000, were imported.

— WEDNESDAY last ("Royal Oak Day," 29th May) was observed in the usual way by the hanging out of sprigs of oak, covered with green foliage, on several shop windows in various parts of the country.

— AFTER vines, potatoes, sugar-canapes, and silk-worms, being each attacked by disease, there is now a fresh victim—the tomato. This crop we learn, will suffer much from disease in the south of France this year.

— THE French Minister of War has decided that in future soldiers shall be allowed to be employed by cultivators on their lands. All who require them must forward their demands, through their mayor, to the prefecture of the chief county town.

— THE very remarkable group of succulents shown at the Royal Horticultural Society's exhibition, South Kensington, last Wednesday, by M. Pfersdorff, of Paris, has been purchased by Mr. Peacock, of Saubury House, Hammersmith, whose collection is one of the richest in Europe in such plants.

— A REMARKABLE collection of the finer varieties of German Iris (*I. germanica*), and likewise numerous other species of this family, may now be found blooming in great perfection at the Hale Farm Nurseries, Tottenham. Lovers of this fine genus should not fail to shortly visit this establishment, if they wish to see this collection at its best.

— THE finest specimen we have ever seen of the beautiful Rocky Mountain Columbine (*Aquilegia caerulea*) is now in flower, planted out in Mr. Parker's nursery, Tooting. It is when well done the queen of the family, and is as fair and as beautiful an example of lovely colouring as any hardy plant we possess. Those who do not know this Columbine should make a point of seeing it.

— THE Central Park at New York has recently been embellished by what is considered to be a very fine statue of Shakespeare, the work of the celebrated American sculptor, Mr. Ward. We suppose the as yet un laid-out parks of Alaska or the Yellow Stone Valley will be embellished with statues of our great bard before Hyde Park, Kensington Gardens, or the Thames Embankment.

— A FINE bush of the by-no-means-commonly-grown Tree Lupine (*Lupinus arboreus*) is now in great perfection at the Exotic Nursery, Tooting. The plant is about three and a half feet high, and its racemes of rich golden yellow flowers are so freely produced as to make it appear, at a distance, to be a complete mass of bloom. For the ornamentation of shrubby borders this fine Lupine deserves attention.

— THE effect of the cold and wet month through which we have just passed, has been, on the whole, favourable to market gardens round London. They at present seem teeming with fertility, and have evidently been greatly benefited by the abundant rains. Everything looks well except kidney beans and asparagus, both of which have suffered somewhat from cold; cuttings of the latter have, up to the present, been much fewer than usual.

— CATERPILLARS this year have committed sad havoc among fruit bushes. Dusting with newly-ground white hellebore powder has, however, effectually cleared them of these pests. A few weeks after the first dusting the caterpillars reappeared. Applications of the same powder were repeated, i.e., of some saved from the first dressing. These proved powerless. A dose of freshly-ground powder was resorted to, and this again cleared the bushes. Powder in a fresh state is, therefore, a *sine quâ non*.

— A FOREIGN contemporary says tea and coffee are threatened with a Brazilian rival called guarana. Guarana consists of the seeds of a tree known to botanists as the *Paulinia sorbilis*, which is very abundant. The tree produces a fruit about the size of a walnut, containing five or six seeds. The seeds are roasted, mixed with water, and dried. Before being used they require grinding, when they fall into a kind of powder. The active principle is an alkaloid, identical with that found in tea or coffee, but there is twice as much of it in guarana as there is in tea. The effects are similar to those of tea and coffee.

— WE have received from Mr. Henry Winthrop Sargent, whose beautiful gardens on the Hudson we had the pleasure of seeing in 1870, information as to terrible destruction by frost which has taken place among his fine collections of conifers and other trees and shrubs. Mr. Taplin, formerly of Chatsworth and now of South Amboy, New Jersey, also informs us that there has been enormous destruction of trees and shrubs throughout all parts of the States east of the Rocky Mountains. A curious feature connected with the destruction, is that some plants, such as the *Cryptomeria* and *Ilex latifolia* have escaped, while kinds supposed to be indestructible, such as the Hemlock Spruce and the field Maple, have been destroyed. Of these disasters we shall publish some details next week.

— THE Epping Forest Bill, which is now before the House of Lords, has been referred to a select committee, consisting of the Duke of Manchester, Earl Stradbroke, the Earl of Effingham, Viscount de Vesci, and Lord Montague of Brandon. The committee will meet on Monday next.

— VERY good and well-flavoured fruits of the Loquat were shown the other day at South Kensington, by Mr. Colbourn, of Woolhampton Gardens, Berks. They were grown against the back wall of a warm conservatory, in a border consisting of peat and loam. They flowered in November, when the blossoms, which come very thickly, were thinned, leaving about six or eight on a spike. While in bloom, the atmosphere was kept dry and maintained at about 50°, fertilization being assisted by means of a camel's-hair brush. The fruit ripened about the end of May.

— AT this season the celebrated Strawberry beds near Dublin attract numbers of people to them belonging to that city. The "beds" are situated on the high sloping banks of the Liffey, just outside the Phoenix Park, through which the drive to them is one of the pleasantest with which we are acquainted. The season at this popular resort lasts from the first Sunday in June to the middle of July, during which time the place bears somewhat the aspect of a fair. This season we learn that the cream is waiting for the strawberries, and that the strawberries are waiting for summer heat.

— A LADY residing in the West End has been appealing through the *Daily Telegraph* for flowers for the sick in hospitals and elsewhere, and has been liberally responded to. The flowers sent have come quite fresh, and the exceeding pleasure they have given has been even beyond what was expected. They have been shared amongst the sick, the old, the insane, and the hard-working needle-women. Each day fresh applications for weekly nosegays are received. Let us hope, therefore, that a work so well begun may be continued, so as not to allow poor people to be disappointed of so pure a pleasure.

— BEDDING out in the London parks, so long delayed on account of the weather, is now being forwarded with vigour. At Battersea pelargoniums and similar common summer and autumn flowering plants are already put out; also the harder subtropical plants, such as *Acacia lophantha*, variegated *Yuccas*, New Zealand flax, and *Alocas*. A new feature, and a promising one, consists in filling up some of the beds with specimen fuchsias, below which the ground is carpeted with *Amarantuses*, and edged with suitable plants. These fuchsias are at present protected with canvas. *Alternantheras*, or any of the more tender plants, such as *Ficuses*, palms, *Dracenas*, &c., are not yet put out, the middle or end of the month being considered soon enough for such plants.

Bedding Out.—The *Daily News* is becoming quite horticultural. The other day it had an article on "bedding out," the general tendency of which was that although bedding was objectionable, it was nevertheless the right thing after all! A correspondent combats this view, and adds, "There is nothing new under the sun, and the modern flower garden appears to me a carrying out of what I saw in 'The Great Central Flowering Kingdom,' twenty years ago; our Chinese house-boy used daily to lay out a large plate of many-coloured flowers, in a kaleidoscope pattern, which seemed to change every day (though I believe the forms were all old, handed down either by books or tradition); the effect was startling; it was beautiful; but it was artificial. An English lady came out to the far land to be the Mistress of the Hong; and she, fresh from a country parsonage—loving and understanding flowers—laid them out in her own fashion; it seemed as if by instinct, not by rule. We never wished to return to the kaleidoscope; and so I think it will be with modern flower gardening."

Leicester Square.—If, according to the orthodox political theory, destruction is a necessary preliminary to construction, we may hope that Leicester Square is about to enter upon a new and a better era. The bare space cannot possibly be left unoccupied, and something must be done with this "improving locality." All sorts of suggestions have been made for utilising the vacant land; but they all seem to err by the assumption that it should be built over. The example of Paris ought to teach us how such an unoccupied waste can best be made use of. Every visitor to the French capital knows the Square Montholon, the plot by the Chapelle Expiaatoire, and a dozen other similar places—which a few years ago were a bare and barren as Leicester Square, and which, under the Empire, were converted into charming open gardens, with flower beds, trees, walks, and benches. There is absolutely no reason why in Leicester Square we should not have a public plot of garden like that of the Montholon in the Rue la Fayette—an oasis in the desert of London.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL REPORTER.

INDOOR PLANT DEPARTMENT.

Conservatories.—The beauty of Camellias is over; Azaleas will soon be in the same condition; and Roses, although so grand a few weeks ago, are now past their best. Acacias, Rhododendrons, Heaths, and other hard-wooded plants are now contributing to the beauty of indoor structures. Any appearance of mildew on Heaths is immediately checked by dusting them with sulphur; in the centre of large plants mildew often develops itself unnoticed, a circumstance which renders it necessary to keep the central shoots thin; such prunings are used for propagating purposes. To Fuchsias one stake only is placed as a support, the lateral branches being allowed to hang gracefully down. Petunias are now very fine, and are supplied occasionally with liquid manure.

Stoves.—A genial moist temperature is now maintained in these; the syringe is freely used amongst growing plants, and fumigating is frequently practised in order to keep down insects. *Cycas revoluta* is often affected with scale, for which the only sure remedy is hand washing. Zamias and Palms making young leaves are never allowed to receive a check from cold draughts or to be in want of water. Creepers are pruned, trained, and luxuriant growths stopped, in order to induce them to form good specimens. *Allocasias* and *Martantas* are kept above water tanks to encourage their growth.

Orchids.—During bright sunshine these receive a little shade, such as arc in flower are removed to a cooler and drier house than that in which they are grown, and they receive more shade in order to prolong their flowering period.

Ferns.—These now enjoy a steady moist temperature and plenty of shade. Sprinklings from the syringe are occasionally given; but care is taken to keep the foliage of *Gymnogrammas* and *Adiantums* always dry.

Pots and Frames.—These are now mostly cleared of bedding plants, and are filled with *Pelargoniums* for late flowering, and other plants. *Verbenas* are being increased in gentle heat, to take the place of early annuals, or other plants that are likely soon to be done blooming. *Cinerarias* are sown immediately the seed ripens, either in gentle heat, or in cold frames; *Auriculas* from seed, which is gathered as soon as ripe, are potted off singly and kept in cold frames; *Chrysanthemums* are shifted as they require it, and liberally supplied with water. *Heartsease* are increased from cuttings in frames with a north aspect. Young *Fuchsias* are being shifted, using a light rich soil, and supplying them plentifully with water. *Balsams* and *Cockscombs* are shifted, as they require it, never allowing them to become pot-bound; if a little bottom heat is given, and at the same time some top air, it greatly improves them.

The Flower Garden.—Most people are now busily engaged in planting out summer bedding plants. In a few places, where they were turned out about the middle of May, they seem to have suffered a good deal. The hardesty plants are put out first, and some of the more tender kinds will not be trusted outside before the middle of the month. Beds are being filled with *Pelargoniums*, *Calceolarias*, *Verbenas*, *Lobelias*, *Gazanias*, &c., and in sheltered positions even *Dahllias*, are being planted out. Where long lines of these are made, the stakes are first driven into the ground, holes being taken out at their base, and a spadeful or two of good rich manure put into each hole and mixed with the soil; the *Dahllias* are then planted, and tied at once to the stakes. Variegated *Yuccas*, *Acacias*, New Zealand Flax, and a few other graceful plants are being planted out, either in beds or as isolated specimens. Edgings of *Echeverias*, *Mesembryanthemums*, &c., are also being made. *Centaureas*, *Solanums*, and *Tobacco* plants are likewise being planted out. Some of the more tender plants have inverted flower-pots placed over them at night. *Alternantheras*, *Palms*, India-rubber plants, *Monsteras*, *Anthuriums*, Tree Ferns, &c., are not yet put out. Herbaceous plants, such as *Lupines*, *Delphiniums*, *Pyrethrums*, &c., are being staked; and to *Phloxes* and similar plants a good surfacing of old hot-bed manure or leaf mould is given. Hardy annuals are being transplanted from seed-beds or from other places where they have been sown too thickly. Half-hardy annuals are also transplanted out of doors, and amongst them the beautiful *Amarantus salicifolius*.

INDOOR FRUIT DEPARTMENT.

PINES.—Suckers are removed and potted as they become ready. Plants, the fruit of which is swelling, receive occasional waterings

with weak manure water and an abundant supply of atmospheric moisture.

VINES.—Such as are colouring, constantly receive a little fire heat, also a little air night and day, but whilst the weather continues dull, only a very little top air is left on at night. Later crops receive no fire heat, except such as are in flower, in order to assist the setting of the fruit. To put vines, manure water is frequently given. Thinning the fruit and stopping the shoots are being attended to.

PEACHES AND NECTARINES.—To ripening crops, a liberal supply of air is given in favourable weather, and a decrease of moisture. Those stoning enjoy a steady genial temperature; later crops are being thinned and disbudded. Top-dressings of good rich material are given to those in pots, keeping it towards the outer edge of the pots, and half-an-inch higher than the rim, so as to leave a small basin in the centre, to hold water.

FIGS.—To such as are ripening their fruit, a steady temperature is maintained; plenty of air is given them, and they are kept rather dry. Plenty of water, both at root and overhead is given to advancing crops.

MELONS.—As the heat in frames begins to decline, fresh linings are applied, and the frames are matted up at night. Top-dressings are given to the beds, and such fruits as are swelling are placed on slate tiles, or pieces of wood.

CUCUMBERS.—Borders in pits are top-dressed with rich material, fruit and foliage timely thinned, and liberal waterings given at the root and overhead.

FRONT BEANS.—These are top-dressed as soon as they show flower, removed to cooler houses or pits, plentifully supplied with water, and kept near the glass.

EGG PLANTS AND CAPSICUMS.—These are kept near the glass in cool pits, and watered abundantly.

HARDY FRUIT AND KITCHEN GARDEN DEPARTMENT.

DISBUDDING OF PEACHES, NECTARINES, APRICOTS, AND CHERRIES now claims particular attention, and the thinning of the fruit is also being attended to. In the case of Peaches and Nectarines, a good many more than are required for a crop, are left on the trees, as during the stoning process many drop off. Figs are stopped at the fourth or fifth joint; they receive very little further thinning. Trees on walls are frequently syringed vigorously to dislodge any insects that may harbour about them. Standard fruit-bushes have any superfluous young wood that may come up in the centre of each bush removed. On the least appearance of caterpillars they are dusted with newly-ground white hellebore powder. Those bushes, the fruit of which is near the ground, have a layer of rank litter spread under them, so as to prevent heavy rains destroying the berries with sand.

STRAWBERRIES.—These are being mulched with rank litter; liberal applications of manure water are also given to them.

BEANS.—A few of the early long-pod are being sown. Those furthest advanced are now podding. Succession crops are in flower, and are topped when about 2 or 2½ feet high. Earth is drawn to advancing crops.

Broccoli.—These are planted out as space permits. A small sowing is made for a late crop.

BRUSSEL SPROUTS, CABBAGES, AND CAULIFLOWERS.—Plant out as ground becomes vacant. For Coleworts, a few dwarf early Cabbages are sown. Cauliflowers are greatly benefited by applications of manure water.

CELERI.—The earliest is planted out, two lines in a trench fifteen inches wide and six or eight inches deep, with a ridge of three feet between the trenches. Succession crops are fully exposed, and a small sowing is made for late spring work.

CUCUMBERS.—Some are planted out on ridges, and protected with hand-lights, over which litter is placed at night.

ENDIVE.—A little is sown on a warm border, and some of the previous sowings are planted out.

KIDNEY BEANS.—A little earth is drawn to these; succession crops are sown on warm borders.

LEeks.—March sowings are being transplanted in lines twelve inches apart, and six inches plant from plant.

LETTUCES.—Some are sown for succession on cool shady spots, others are transplanted as required, and strong plants are being tied up for blanching. Those put in between lines of young Strawberries are removed for use, in order that the ground may be mulched, to save the fruit from grit.

NEW ZEALAND SPINACH.—The main crop of this Spinach is being planted out.

ONIONS.—Where these have come up thickly, either in beds or lines, they are thinned out to a few inches apart. When in beds, Lettuces, Parsley, and early Carrots, are frequently sown with them; these

are now thinned out considerably, allowing none of them to stand one another than fifteen or eighteen inches.

PARSNIPS.—These are thinned to about ten inches apart.

PEAS.—A sowing of tall Marrows is being made for late autumn use, in lines six feet apart, the intervening space being planted with Cauliflower, Brussels Sprouts, or Cabbage.

POTATOES.—Those planted on wall borders are now advanced so much that the rows are meeting one another; to main crops earth is being drawn, carefully avoiding packing the soil.

SPINACH.—Successional sowings are being made between lines of Peas, or it is sown broadcast on ground newly planted with Cabbages and Cauliflower.

TOmATOES.—These are planted out along the base of walls, or on warm borders; little basins are left around each plant, so as to permit of watering being freely given, should such be necessary.

TURMIPS.—The last sown crop is being thinned.

SMALL SALADS, are sown every ten days, according to the demand.

NURSERIES.

INDOOR PLANT DEPARTMENT.

A good deal of time is consumed at present in preparing plants for exhibition. In many cases those that have been shown have suffered considerably, especially the young fronds of Palms, which are now subjected to a strong heat and plenty of moisture and shade. Bedding plants turned out of frames are placed between hedges or in other sheltered places. The frames have been filled with Heaths, Roses, and other greenhouse hard-wooded plants. Heaths, Epacries, &c., growing vigorously in frames, are kept a little close, and are carefully shaded; the young wood as it advances is pinched, in order to make the plants bushy.

The propagating of Begonias from leaves laid on the surface of a pan, of which half an inch of the surface is white sand, is being proceeded with. Some of the kinds are increased by means of cuttings, as are also Gesneras. Gloxinias are also increased by means of well-matured leaves, not too old; these are inserted up to their necks in sand, kept under hand-lights in the propagating pit, and closely shaded for a time. Seedlings of all kinds are being potted off singly as they become fit. Maurandias from seed are potted singly and staked; Melianthus, Coronillas, and Cytisus are also potted singly and placed in cold frames. Gonophræna globosa and Mimosa pudica, from seed-pans, are potted singly, using a light rich compost for the purpose; the plants are kept for a time in gentle heat. The young shoots of Primula sinensis are taken off and inserted singly as cuttings in small pots. Old plants of variegated Thyme continue to be forced for cuttings, which now root freely in cold frames; those rooted are repotted or pricked into boxes. Cuttings of Statice continue to be shifted, never allowing the plants to suffer from want of root room. Young Palms from seed are potted singly into thumb or sixty-sized pots, and receive abundance of heat, moisture, and shade. Rooted cuttings of Deutzias, and plants of Plumbago, &c., are repotted and kept rather closely in cold frames.

OUTDOOR DEPARTMENT.

Seedling Conifers in beds are now up, and are immediately cleaned, for as they are slow growers they are apt to be choked. Plants in seed-beds are seldom thinned, as they are commonly transplanted after the first year. From grafted trees all suckers are removed as they appear. The grafts are frequently examined, and the clay renewed should it be loosened by the weather. Conifers, deciduous and evergreen trees grown in lines, are being cleaned; also walks and edgings. From about the roots of hedges, all weeds—both annual and perennial—are removed. Young fruit trees are being attended to as regards training and disbudding; unless when requisite to test the kind, no fruits are allowed to come forward. Herbaceous plants are being staked and top-dressed; those in pots are also being surfaced and top-dressed.

MARKET GARDENS.

Notwithstanding the backwardness of the season, crops in market gardens look well. The first crop of Cauliflower, i.e., those reared under hand-glasses, furnishes abundance of heads; and now the second crop, or those of the first planting in lines, are beginning to yield abundantly. Lettuces are in great perfection, especially those grown by themselves; those that have been planted between other crops are also of fine quality, and are removed as the more permanent crops begin to occupy the space. French Beans are a little injured by cold winds, but such as have been protected under hoops and mats, look fresh and well.

ASPARAGUS.—Beds of this are now yielding more abundantly than they did a few weeks ago; they have, however, not been so productive as in warmer springs. No shoots are yet allowed to run up; all are cut.

BEET.—The first crop of this sown between lines of Lettuces, fifteen inches apart, is now eight or nine inches high; the lettuces are just being removed for market, and another crop of the same is put in their place. The main crop is being thinned.

CABBAGES, CAULIFLOWERS, AND BRUSSELS SPROUTS.—These are being transplanted, as the ground becomes vacant. A successional sowing of Coleworts is being made on cool, damp soil.

CELERY.—Lines of this are planted four feet apart, the intervening space being in the form of a ridge, about four inches higher than the line of Celery. On the top of this ridge, from one to two lines of Lettuces are planted. In some cases, a few weeks ago, four-foot beds were planted with three lines of Lettuces; between the beds were twelve or fifteen inch wide alleys about six inches deep; these are now planted with Celery about eight inches apart.

CUCUMBERS.—Those in frames are bearing freely, and are closely attended to as regards pinching the points off the vines, a joint or so beyond the fruits; the shoots are being pegged down, and the fruits thinned, placing those inclined to grow crooked in tubular glasses. They receive abundance of water, and to those some time in bearing, a little liquid manure is also applied. After watering, and during bright sunshine, a little litter is scattered over the lights, to act as a kind of shade; the frames are also covered with litter at night. Some Cucumbers are likewise planted out in ridges, but the vines are kept as much as possible under hand-lights.

KIDNEY BEANS.—In exposed situations these have suffered a good deal from cold winds, but where they have been sheltered they are progressing favourably. Those protected by hand-lights, and in beds surrounded by mats, are making rapid progress. Some are just appearing above ground, and to succeed these another sowing is being made. The lines are three feet apart and cropped between with Lettuces or Turnips.

LEeks.—These are being transplanted in little furrows in lines a foot apart; those planted some time since, have the furrows filled up by repeated hoeings.

MINT.—This is now abundantly produced on pieces of damp soil, and in places where little else could be grown. It forms a permanent crop, the only care taken being to exterminate weeds. Fresh plantations are also made in shady cool places in lines a foot apart; in the intervening space between every third and fourth line, a row of Lettuces is planted.

ONIONS.—Transplanted ones from the autumn sowing are now being gone over, and all those showing flower are pulled and sold at a low price; those still remaining in the autumn-sown beds are being cleared for market, and the ground devoted to other crops. Broadcast spring sowings are being cleaned a second time with harrow hoes. The last sowings for drawing young are just appearing above ground.

PARSNIPS.—The first crop of these are eight or nine inches high, in lines fifteen inches apart; between every second and third row a line of Lettuces is planted. The main crops are being thinned a second time to about eight inches apart.

PARSLEY.—Old plants under the shade of trees furnish at present a good supply; about two months since along with the Radishes some Parsley seeds were sown in beds. As the Parsley takes a much longer time to germinate than the Radishes, the last was removed from the bed immediately after the Parsley made its appearance, so these now form the succession crop.

SEAKALE.—Old plants are now allowed to develop themselves, and are in full bloom. Overcrowding of foliage is prevented by thinning. From young plantations made this spring, intermediate crops are removed.

STOCKS AND ASTERS.—Young plants remaining unsold, are planted in lines six inches apart each way, where they will be kept for cut flowers.

SWEET MARJORAM AND OTHER HERBS.—Those raised in frames are now planted out in lines a foot apart, in separate plantations or in alleys between other crops.

TOMATOES.—Plantations of these are made in the open ground in sheltered positions, in lines three feet apart, and eighteen inches between the plants in the line. Those still unplanted are kept in pots plunged in cold frames, but fully exposed.

TUNNIES.—Early sowings have all been removed, and Kidney Beans, Tomatoes, or other crops occupy their place. From main broadcast sowings the supply is now derived. Some are advancing, and are being thinned. When necessary, another large sowing is being made.

VEGETABLE MARROWS.—Those first planted out on ridges, heated by a little manure, are now growing strongly without any covering; others are kept under hand-lights; and those planted out without any bottom heat, if protected, are making some progress; if unprotected, they are doing little good. Fresh plantations are being made in the ground occupied by Mushroom-beds.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY.

[JUNE 5TH.]

The opening day of the great show of the season was as fine and sunny, and as agreeably tempered with a refreshing breeze, as could be desired, and, on the whole, the interest and beauty of the show were of a very high order. There was, besides the great exhibition of Rhododendrons by Mr. A. Waterer, and the usual interesting novelties in the Council Room.—

NEW PLANTS.—The prizes for these brought forward a number of beautiful novelties, most of them in a much finer condition than the public has heretofore had the pleasure of seeing them. The first prize group in this section, shown by Messrs. Veitch & Sons, King's Road, Chelsea, consisted of the following remarkable plants: Dracena Dennisii, Pandanus Veitchii, Begonia Chelsoni, Dracena Mooreana, Epidendrum synoecysis, Nepenthes Sedieri, Croton Hookeri, Begonia Sedieri, Todea Wilkesiana, and Cyrtosia undulatum. The second prize group, shown by Mr. Ball, was enriched by a fine specimen of the very handsome Bertolonia guttata splendens, the giant, Arum-like Godwinia, and the palm-like Curcullaria reticulata striata. The first prize for six plants in or out of flower, introduced by the exhibitor, and not in commerce, was won by a group shown by Messrs. Veitch, consisting of the following plants: Adiantum speciosum, a vigorous, distinct, and most graceful fern; Croton Youngii with a dark green mottled sword-like leaf; Dracena amabilis, a handsome kind, with white and reddish variegation; Dracena spectabilis, with pale crimson bands and margins, a very remarkable species; Araea Veitchii, a graceful and delicate kind, with a narrow crisp undulated leaf. In the second prize group, shown by Mr. Bull, there were three remarkably striking new plants, Bertolonia superbaissima, which may be called the queen of spotted-leaved plants; Diefenbachia nobilis, a noble looking kind, and Alcosmia illustris. Botryodendron magnificum, a noble fine-leaved plant, with glossy foliage, having a metallic green hue, was shown by Messrs. Downie, Laird, & Laing. It is likely to prove a distinct and valuable plant. One of the most beautiful plants we have seen for a long time is the remarkable Utricularia montana, shown by Mr. Denning, gardener to Lord Londesborough. Its large white flowers, with yellow spots, abundantly produced and gracefully pendent, looked exactly like those of some fair and well-grown Orchid. It is at once a great curiosity, differing, as it does, so wonderfully from its little British relatives, and is a plant of the very highest value in an ornamental point of view. Very singular, too, among Orchids, was Nanodes Medusa, shown by the same exhibitor. Its quaint flowers, seen beneath the eye on the council room benches, looked quite dull in hue; but placed so that they came between the eye and the light, this colour was at once changed to a bright magenta. The same exhibitor showed one of his brightly-coloured Masdevallias, which are likely to prove as marked an addition to the Orchid family as the Anthurium Scherzerianum is to our Stove Arms. In a mixed group of plants shown by Messrs. Veitch, fine examples of Aracaria Rulei and A. elegans were conspicuous for their merit; also a large basket of the brilliant Begonia intermedia, and the finest specimen we have ever seen in this country of the Californian Pitcher Plant (Darlingtonia californica). A remarkable group of plants came from Mr. Kellogg, of Stoke Newington. This consisted of the most graceful specimen of Beaucarnea we have ever seen. It was accompanied by Yucca Treculeana and Puya coacta.

STOVE AND GREENHOUSE PLANTS.—In these classes Mr. Baines, of Southgate, was his, specimens being, as usual, very remarkable ones, especially his noble American Pitcher Plants. Among other plants from Mr. Baines, was a very fine Ixora coccinea, two years and nine months old from the cutting stage. The collections from Messrs. Ward & Donald also contained some good plants, as did also others, especially that contributed by Messrs. Jackson, of Kingston, to which a first prize was awarded. Plants remarkable for the beauty of their leaves were also numerous, Mr. Baines being foremost in this class, and a good collection of them was also shown from Ghent, by M. Dallière; Mr. Cole & Mr. Donald also showed good collections.

PYRETHRUMS.—It is very probable that these plants will soon beat the Chrysanthemums, both for beauty and variety, as well as for the size of their blooms. Messrs. Kelway & Son, of Langport, Somerset, had a first prize for a fresh and well-grown collection. Why not show these plants in pots, in which they form very fine specimens? Messrs. Veitch exhibited an interesting collection of them, not for competition.

ORNAMENTAL GRASSES.—Judging by the list of these in our catalogue, one would think that ornamental grasses were well understood in gardens; but the fact is there is no family so imperfectly known from a horticultural point of view. Many of the comparatively few really ornamental kinds we now grow, are often passed off as distinct grasses under distinct names. We were, therefore, pleased to see a very fine collection of grasses shown by M. L. Bassauts, Botanic Garden, Ghent. These were deservedly awarded an extra prize, and should be seen by all who take an interest in the subject.

HERBACEOUS PLANTS.—Considerable improvement was manifested in the showing of these as cut flowers. Mr. Ware's collection being exceptionally fine. By the way, we will venture to suggest that, in this class, as well as in others in which shallow baskets are used, it would be very desirable to conceal their ugliness by allowing some trailing plants to hang over them.

THE GARDEN.

TREE CARNATIONS AND PICOTÉES.—A very marked advance was evidenced in these as shown by Mr. Charles Turner, of Slough. Pyrothums, Fancy Pansies, and various other flowers have shown striking improvement of late. But we don't consider any recent gain so precious for the garden as those large and well marked tree Carnations and Picotées. The blooms seemed even larger than what are commonly termed the finest florist's varieties, and the colouring quite as delicate and true. The fact that they may be had through the winter and spring, and indeed almost all the season, should make them very precious to all who have to provide cut flowers.

PELARGONIUMS.—These were wonderfully fine, and well bloomed, some as much as four feet in diameter. They were also well variegated as regards colour, which at June shows is always bright and beautiful. A group of seedlings from Mr. Foster caught much attention; those among them to which certificates were awarded are enumerated below.

ROSES IN POTS.—The only exhibitor of these was Mr. George Paul, who furnished a charming group fresh and beautiful. Besides those in pots, he likewise showed some fine boxes of cut blooms, as did also Messrs. Kilway & Son.

HEATHS.—These were shown on the whole in better order than usual. Some of them were of wonderful size and beautifully flowered. The only fault observable was the stiff way in which some of them were trained, the natural habit of the variety being completely lost sight of. Striking novelties are still much wanted in this class.

FERNS.—These filled conspicuous positions with refreshing verdure. Both hardy and tender kinds were shown in profusion. Among the latter was a splendid plant of *Adiantum Farleyense*, from Mr. Williams; who likewise contributed grand examples of *Gleichenia* and *Davallias*, and also some fine tree ferns.

ORCHIDS.—Of these there was a tolerably good display. Among them one of the most conspicuous was *Saccobium guttatum Holtonianum*, on which there were no fewer than seven fine spikes of bloom. This came from Mr. Williams, of Holloway, and *Epidendrum vitellinum magus*, unusually well coloured, by Mr. Wilson Saunders. Amongst other Orchids were the somewhat rare *Dendrobium McCarthyi*, and good well-flowered examples of *Anguloa Clovesii*. There were also some fine plants of *Aërides* and *Cattleyas*, especially *C. Warneri*, a richly coloured and fine variety.

CUT ORCHIDS.—A rich and beautiful collection of cut blooms of Orchids was shown by Provost Russell, of Falkirk. They were gracefully arranged, and very suggestive of the vast improvement orchids in a cut state are likely to effect in arrangements of cut flowers.

SUCULENTS.—These plants have fallen on happy days at last. After having been banished from our gardens for years, Mr. Peacock, Mr. Wilson Saunders, and others, have shown us what great merits they possess, and we may soon expect to see them taking their proper place in our gardens. A fine collection was shown by Mr. Peacock on this occasion. M. Pfersdorff's collection, long known to be the richest of all in curiosities, contained the most extraordinary example of a grafted Cactus we have ever seen. It was a huge *Echinocactus Pottsii*, about fourteen inches in diameter through the body, supported on three legs of a cylindrical *Opuntia*, none of them more than an inch and a half through; such a giant head and diminutive legs we have never seen before, except in the cartoons of some of our comic contemporaries. The art of grafting as applied to succulents, is truly productive of wonderful results.

PANSIES.—These old favourites we were pleased to see well represented by Mr. Bragg, of Slough, Mr. Hooper, of Bath, and other growers. Remarkable among these was a splendid strain of Fancy Pansies, shown by Messrs. Downie, Laird, and Laing, which for size, novel and rich markings, would have made a little show of themselves. A Pansy, shown by Mr. Ware, named *Pluto*, which received a first-class certificate, was the blackest and glossiest object we have ever seen in the shape of a flower. Oliver Wendell Holmes says, that "a florist's Pansy is coloured by his flowers, and that nature never shows him a black corolla." But here we have it at last.

BASKETS ARRANGED FOR EFFECT.—In this class the first prize was well earned by Mr. Cole, Ealing Park Gardens. It was, perhaps, the most tasteful basket of plants we have ever seen. The basket and its support were completely concealed by fresh-growing *Lycopodiums*, and from the centre of the group sprang a tall, graceful young Palm (*Cocos*), which completely relieved it from the squatness of form so common to compositions of this kind. Miss Williams, who won last year, was second. A very attractive basket was also shown by Mr. Ware. It consisted wholly of herbaceous plants, and although it did not get a prize, it seemed to us to possess much merit.

CAPE BULBS.—Many of these beautiful flowers, which either our climate or want of knowledge of their requirements prevents us from seeing to advantage in this country, were shown in brilliant bloom by Messrs. Hooper, of Covent Garden. Their charms are sufficient to encourage us to persevere with their culture till we succeed in growing them. We think there is no reason why they should not be seen in the milder and warmer districts of southern England in nearly as great beauty as in the Channel Islands.

CERTIFICATES.—First-class ones were awarded to *Utricularia montana*, from Mr. Denning, to Tree Carnation Model, a very finely shaped white flower from Mr. Lee Horst, Aspendale; to *Dasyphyllum glauca*, one of the finest of its class, being almost white on the under side of its long thorny leaves, and also to *Puya caeruleata* and *Yucca Treculeana*, above alluded to, from Mr. W. B. Kelcock, Stamford Hill. A similar award was likewise

given to *Nanodes Medusa*, from Mr. Denning. Like awards were also bestowed upon the following Pelargoniums, all from E. G. Foster, Esq., Clewer: Syren (with fine dark upper petals), Prince of Wales, Ruth, Druid (well-shaped), Robin Hood (fine dark upper petals), Highland Lassie, Duchess, Scottish Chieftain, Senator, and Countess; also a second-class certificate to Blue Bell. A first-class certificate was likewise awarded to Pelargonium Captain Raffles, a beautiful showy fringed kind, from Mr. R. Weatherill, florist, Finchley, and to a most excellent Zonal Pelargonium, named Richard Cour de Lion, with large brilliant scarlet symmetrical flowers from Dr. Denny, Stokes Newton-on-Ouse, and to Petunia, King of Crimson, a good double crimson; and also to a beautifully formed fern, named *Pteris serrulata cristata*, from Messrs. Dickson & Co., 48, Margate Street. A first-class certificate was likewise conferred upon Aquilegia aurea, a distinct kind from any others of its class, from Mr. Ware, who also received the same award for a black Pansy named *Pluto*. A first-class certificate was awarded to Botryodendron magnificum from Messrs. Downie, Laird, & Laing, and to *Euphorbia hababeania* monstrosa from M. Pfersdorff, Paris.

FRUITS.—Considering the season, were exhibited in tolerable profusion. Pine-apples were abundant, and of first-rate quality; they consisted chiefly of Queens. In classes for Grapes there was a keen competition, both as regards light and dark coloured sorts. Some of the bunches, although very large, were not quite ripe, and it seemed almost a pity to have cut them so soon. Black Grapes consisted of Black Hamburg, Black Prince, and Grizzly Frontignac; amongst the white ones were Buckland Sweet-water (splendid examples from Mr. Douglas, Loxford Hall, Hford); white Muscadine, Golden Hamburg, Ascot Citronelle, from Messrs. Standish & Co., and Foster's Seedling. Of Peaches there were several dishes of excellent fruit, highly coloured and well ripened; they comprised Royal George, Gross Mignonne, and Bellegarde. Nectarines were also fine in quality, and consisted of Erleng and Violet Hatton. Figs were remarkably fine, the kinds being Brown Turkey and White Marsilles. Cherries were exceptionally fine, and exhibited only by Mr. G. T. Mills, gardener to Lord Carrington, Wycombe Abbey; the kinds Black Circassian and Elton. Strawberries were abundant, very fine, and of excellent flavour; they consisted of Sir Charles Napier, President, and British Queen. Amongst fruits perhaps there was nothing so interesting as the collection of Melons, which included pale and scarlet fleshed kinds. Pale fleshed sorts comprised Colston Bassett Seedling, Green Hybrid, Victory of Bath, Conqueror of Europe, The Sultan, Hybrid Cashmere, and Golden Queen. Scarlet-fleshed kinds consisted of Scarlet Gem, Little Heath, Lee's Hybrid, Malverne Hall, and Scarlet King. Of Cucumbers there were several examples of Blue Gown, a large fruited kind. There was also a fine box of ripe Tomatoes. Of old Apples two kinds were shown in a state of good preservation; they were Cornish Aromatic and Easter Pippin. Two nice examples of Juneteating were exhibited by A. Snee, Esq.; they were grown in an orchard house. Amongst miscellaneous fruits, the Loquat shown by Mr. Colbourne excited most attention.

THE RIODODENDRON EXHIBITIONS.

Once more the Regent's Park and South Kensington are embellished by those brilliant little American garden plants, now famous over the gardening world. They feebly represent the amazing beauty of the great Rhododendron grounds of Knaphill and Bagshot, where the Rhododendrons have been brought to greater perfection by the Waterers than even they have been seen on their native hills; so at least the Americans tell us. Although to some these exhibitions may appear monotonous, they are by no means so to those who annually look for new and improved varieties; while to the general public, like bluebells and nightingales, they are ever new. Both exhibitions this year are fully up to their usual merit, both in extent, profusion of bloom, and novelties, and we hope to have the pleasure of speaking soon of their more important features at greater length.

The Climate and Vegetable Products of Persia.—It is a popular error to suppose that the climate of the whole of Persia is tropically hot and its soil rocky and sandy. On the contrary, in the southern provinces the climate is most delightful, and there is probably no spot in the world more lovely by nature than the neighbourhood of Isphahan. The heat consequent upon the latitude of Persia is greatly tempered by the height of ground, which is generally a table land supported by high mountains. The natural products, vegetable and mineral, of this country are prodigious. The vine flourishes in several provinces, and the wine of Shiraz is as famous in its way as Tokay or Johannisberg. In the northern provinces the mulberry is universally cultivated, and the silk produced thereby is inferior to no other growth, while the quantity is far above the average. In the fecund plains of Gilan and Mazanderan the sugar cane flourishes with a vigour unsurpassed in the West Indies or Southern States, but the value of this staple is almost nullified by the want of due appliances in refining the sugar. Indigo, cotton, hemp, hops, opium, and the liquorice plant are found in Persia, all of exceptional quality, although produced with the minimum of care or skill. All the favourite European fruits grow here with hot-house luxuriance and flavour. The melons of Isphahan are the finest in the world. There also exist in sheltered situations splendid and almost illimitable tracts of rich land suitable for the cultivation of timber of all valuable kinds.

COVENT GARDEN MARKET.—June 7th.

Flowers.—These, both from stoves and greenhouses, are plentiful, especially in the form of cut blooms. Of hardy and half-hardy annuals there is also a good supply; these consist chiefly of Nasturtiums (about six inches high, sown thickly in six-inch pots) and Sweet Peas, treated similarly; also Nemophila, singly, or in small pots, brought to market just as they are beginning to bloom; Prince's Feather and Loves-liest-Bleeding, three or four inches high, in thumb pots; and Stocks and Asters, drawn from the seed-bed, and tied into little bundles. There are also small stubby plants of Balsame and Cookseombs, pricked into boxes about three inches apart, and as soon as they fill up the space they are brought to market in the boxes and sold singly, with a bit of paper or some grass tied round their roots, or wholly by the boxful. In addition to these, there are several herbaceous plants, such as Sweet Williams, lifted with ball just as they are beginning to flower; Pansies, both in small pots and lifted out of the ground with ball; Mimulus lifted from the ground, and small pots filled with Cerastium. Besides these, bedding plants are very plentiful; among them are Pelargoniums of different sorts in small pots, also Caleularia, Heliotropes, Lobelias, Ageratum, &c., all grown in pots. Amongst climbing and trailing plants, are Ivy, also Tropaeolum canarium, Lophospermum, Cobaea, Honeysuckles, Passifloras, and Virginian Creepers; these are all grown in pots and trained to upright stakes.

Why is a Botanist like a Prize-Fighter? Because he is a Phytologist.—G.

BEE-HIVES.

TWO SILVER MEDALS AWARDED TO
GEORGE NEIGHBOUR & SONS, at
the Paris Exhibition of 1867. The only English
Exhibitors who obtained a Silver Medal for Bee-hives.

NEIGHBOURS' IMPROVED COTTAGE BEEHIVE,
as originally introduced by GEORGE NEIGHBOUR &

SONS, working their
bees, and glassy made of
straw; it has three

windows in the lower
hive. This hive will be
found to possess many
practical advantages,
and is most easy of
management than any
other bee-hive that has
been introduced.

Price complete,
£1 15s.

Stand for ditto,

10s. 6d.

THE ITALIAN ALP BEE-HIVE,
being much in repute,
G. N. & Sons supply a
Swarm of Bees with
genuine Italian Queen,

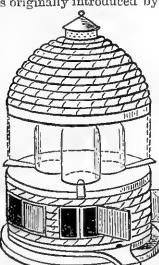

in the Improved Cottage Hive, at £4, Hive included.
An Italian Alp Queen, with full directions for uniting
to Black Stocks, £s. each.

ENGLISH BEES.—Stocks and Swarms may be obtained
as before.

THE APIARY. By A. Neighbour, 5s., postage 4d.
A newly arranged Catalogue of other Improved Hives,
with Drawings and Prices, sent on receipt of two
stamps.

Agents for Straw, Woodberry, and other Hives and
Swars, made by James Lee, of Windlesham, at his
prices.

Address, GEORGE NEIGHBOUR & SONS, 127, High
Holborn, W.C.; or 119, Regent Street, W.

ROCKWORK in PICTURESQUE and
NATURAL forms for FERNERIES, CONSER-
VATORIES, ALPINERIES, HEATHERIES, WATER-
FALLS, CLIFFS, BANKS of STREAMS, PONDS,
LAKES, CAVES for BOAT HOUSES, AVIARIES,
AQUARIAS, &c., with plenty of soil, in and on the
ledges, between the strata and crevices of the rock, so
that the growth may be rapid and have good effect.
Upon other Rock Plants and Shrubs, to grow
freely about the Rocks. Using generally stone or other
materials of the locality. Unearthed Rock broken into
picturesque forms, where it is to be found.

Executed by men who have grown up at it; some
of them nearly twenty years, under my instructions,
JAMES PU LIAM, Broxbourne, Herts.

Expectations for one Stamp, with list of references.

Recommended by the principal Landscape Architects of
the day.

LONDON DEPOT for ROCK or VARIOUS STONE,
also Superior TERRA-COTTA GARDEN EDGING, and
KERB of various Geometric plans for CONSERVA-
TORIES and Jardiniere Borders; VASES, FOUNTAINS,
&c., to be seen at—

5, MARIA PLACE, NEAR LOUGHBOROUGH-ROAD
STATION, BRIXTON, S.E.

(Eighteen minutes' Journey from Victoria Station.)

THE ROCK PART of the SCENERY in the
OAK LODGE and BERRY HILL GARDENS,
which have been so commended in this Journal, was
executed by JAMES PU LIAM, Broxbourne and Brixton,
in the years 1859 and 1864, for picturesque effect. See
illustration in the number for December 30, 1871.

NETTING for FRUIT TREES, SEED
BEDS, RIPE STRAWBERRIES, &c., TANNED
NETTING for protecting the above from frost, blight,
birds, &c., two yards wide, 3d. per yard, or 100 yards,
20s. per roll, or 100 yards, 40s. per roll.

NEW TANNED NETTING, suited to any of the above
purposes, or as fence for fowls, two yards wide, 6d. per
yard; four yards wide, 1s. per yard; 4-inch mesh, four
yards wide, 1s. 6d. per yard. Can be had in any quantity
of EATON & DELLER, 6 and 7, Crooked Lane, London
Bridge, E.C.

ANSWERS TO CORRESPONDENTS.

J. F. (we quite agree with you, and will attend to your request).—J. H. (Acet
platanoideum).—J. GRIMAL (many thanks).—H. J. W.S. (they are usually stopped
at the joint beyond the bunch; but this is not now practised by our best growers,
who leave several joints beyond the bunch; in fact, as many as they have room
for; laters stop above the first joint).—MARY (you will have no difficulty in
getting a coffee plant through any respectable nurseryman).—A. McA. (1. Clay-
tonia perfoliata. 2. Cypripedium. largely developed).—A. variegata
of Potentilla americanus. 4. Achillea millefolium).—NANCY (apparently
a gigantic species of common horse-mushroom). As regards your other
questions—I. Sophie Dumaresque, Mrs. Headley, Prince of Wales, Lady Culmyn; 2.
Excellent, Mrs. Rousby, Princess of Wales, Imperatrice Eugenie; 3. Harrison
Weir, A. H. Wills, Red Ring, Black Douglas; Dr. Ricci, Jen Sisley, Clipper,
Chain; Triumphans, Avalanche, Warrior Queen, Alexandra; 6. Apollo, Thos.
Lawden, Kate Lawden, E. W. Badger; 7. Taylor (the varieties of Rhododen-
dron, and 9. Blattaria).—J. C. (the illustrated edition of Bentham is best; a
cheap and useful book is "Old English Wild Flowers," published by Warne &
Co.).—C. W. (wet the foliage and dust it well with sulphur; there is no better
remedy).—INQUIRIES (Dahlia blooms certainly harbour earwigs, which must be
trapped by putting small flower-pots inverted, half filled with dry moss, on the
tops of the Dahlia roots). By regularly emptying the pots into boiling water,
these pests may be kept in check).

The Language of Flowers.—A woman, not young, having
heard of the success of Effie Carstang, in St. Louis, in recovering 100,000
dollars from her lover, determined to proceed against a suitor of her
own. She accordingly consulted a lawyer in Richmond, submitting, as
the main evidence of his attachment the following billet doux that
accompanied a bouquet of flowers:—"Dear—I send u by the boy a
buckett of flours. This is like my love for u. The nite shaid menes
dark. The dog fenil menes i am ure slave. Rosis red and possai—
My luv for u shall never fail."

The Name and Address of the writer are required with every communication,
though not for publication, unless desired. Letters or
inquiries from anonymous correspondents will not be inserted.

All questions on Horticultural matters sent to THE GARDEN will be
answered by the best authorities in every department. Correspondents,
in sending queries or communications of any kind, are requested to write on one side of the paper only.

All communications for the Editorial Department should be addressed
to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton
Street, Covent Garden, London, W.C. All letters referring to
Subscriptions, Advertisements, and other business matters, should be
addressed to THE PUBLISHER, at the same Address.

Readers who may find it difficult to procure THE GARDEN regularly
through the newsagents may have the numbers sent direct from
the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a
quarter, payable in advance. All the back numbers may be obtained.
THE GARDEN can be had in neatly covered monthly parts.
On sale at Messrs. Smith & Son's bookstalls, and may be had
through all booksellers Part VI. for May, now ready, price 1s. 5d.

EDGINGTON'S GARDEN NETTING,
the cheapest and most durable, at ld. per square
yard, or in quantities of 250, 500, or 1,000 yards, carriage
free.

EDGINGTON'S RICK CLOTHS for 67
years have maintained their celebrity as the best.

EDGINGTON'S MARQUEES for Hire
are the most elegant and capacious.

EDGINGTON'S CRICKET and
GARDEN TENTS are the prettiest.

order to H. BAYLY & CO., Merchants, Great Yar-
mouth.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

THE GARDENS OF ENGLAND.

PACKINGTON HALL, NEAR COVENTRY.

PACKINGTON HALL, seated in a fine wide park and with extensive and interesting old gardens, is of interest to horticulturists for two things above all others—oaks and peaches. These mark it—as Busley Park is dignified by its horse-chestnuts, and Bicton by its noble evergreen trees. To know the oak in its half old age and healthy, full-grown vigour, one must visit Warwickshire; and to know the oak in Warwickshire, one must see the park at Packington. In one part of it they cluster like an army of giants. It is not one big oak to be seen here and another there, but a forest of patriarchs. The wood is dense, and one wonders how the trees grow so large while withal so crowded; yet, standing in one spot, a dozen trees may be seen, any one of which would elsewhere be dignified by a name and be the pride of the neighbourhood. Through the green wood, here and there in the distance, start up what seem to be the bases of small towers, but on nearer approach they are found to be oaks, with such huge, contorted, wide-spreading boles, that one is reminded of pictures of the African tree-giant, the Baobab. Many trees measured—without seeking for the largest specimens—from twenty-six to thirty feet round, and one thirty-three feet at five feet above the ground. Yet to none of these trees would apply Tennyson's comparison of an oak, so hollow, huge, and old,

"It seemed a tower of ruined mason-work,"

for every tree was intact and had a green young head, except, indeed, where the mysterious tree-destroyer we call lightning had struck with his fiery death magic, and riven one of the old mountains of strong fibre as easily as if it were a summer reed. But otherwise,—

"The spring

Finds them not less alive to her sweet force
Than yonder upstarts of the neighbouring wood."

IMPROVED PEACH CULTURE.

There are vast regions of the earth where the climate suits this noble fruit perfectly, the south of Europe and a number of the biggest States and territories in America—from Chesapeake Bay to the foothills of the Sierras, for example, not to mention other lands where the peach is happy as a standard tree. But one has to travel far before meeting with as good a peach as that grown under glass, or against walls, in an English garden. The culture of this fruit under glass has long been admirably practised by our gardeners; but nevertheless, in this, as in almost every other branch of the happy art of gardening, the intelligent cultivator may always hope to advance another step. And Mr. Temple has done it here; his peach culture is the finest example I have seen.

The peaches and nectarines are grown in two half-span houses, each about ninety feet long, eighteen feet wide, and 13½ feet high to the apex of the roof, the back wall being twelve feet high. The trees are trained under the roof in the usual way, only with a little more space between the roof and the tree than is usual, so as to allow of the trees being attended to from the front, and from above as well as from beneath. A narrow passage along the front affords a good view over the whole upper surface of the trellised trees. So far nothing out of the way. The breadth of the front trellises is about thirteen feet; above these there is about six feet of clear space, through which the light enters for the benefit of the back wall

and whatever plants may be beneath. These back walls are covered from the top to the bottom with healthy shoots as regularly dotted with peaches and nectarines as if there were no trees on the roof. As the back wall peaches invariably ripen about a fortnight later than the same kinds on the roof above them, it is evidently a great gain to have the high back walls so perfectly covered.

The trellises overhead are also regularly covered with as fertile peach and nectarine trees as could be seen: many of the fruits of the past year weighed fifteen to seventeen, and even eighteen, ounces each. The most interesting part of the culture here is the rapid way in which the walls are covered. Mr. Temple considers that with healthy young fan-formed trees large houses should be well filled with bearing wood after two, or at most after three, years' growth. In spring he does not cut back in the usual mutilating manner, but allows the young trees to grow as vigorously as they like, till they cover their allotted space. Afterwards their vigour is given off in heavy crops of large fruit. The pruning is simple enough. The old bearing wood of the previous summer is of course cut out in winter or in early spring, but the flowering shoots are not touched till the fruit is set. Once set, both fruit and the shoots of the bearing wood are gradually thinned, the shoots being all removed except a healthy one at the base, which is allowed to grow as freely as it may, and one beyond the fruit, which is pinched in rather closely. In respect of pruning and setting of fruit, however, we have not so much to learn in peach culture as in other ways. Trouble is rarely experienced in getting house peach trees to bear as much fruit as their strength will permit. It is the vigorous tree and the perfectly covered wall or trellis we want, and then, unless the management is not only bad but destructive, the rest follows, almost without trouble. But we also want the vigorous tree and the perfectly covered trellis as soon as possible after planting; and we shall not have to wait long if we give the trees their own way, so far as is not inconsistent with the necessary training. The rule has so often been to cut back so hard in spring and to mutilate so much in pruning at other times, that long years pass as we look in vain for the tree to cover its given place. The whole tendency of the best recent practice both here and on the Continent is that the plan of cutting back hard in spring to secure a good break has caused an immense amount of mischief. Henceforward the aim of good cultivators must be that system of pruning and training which enables us to cover wall or trellis in the quickest and most regular manner.

The soil and water are very important, or rather the most important, points in peach culture. The subsoil at Packington being a good open gravel, no kind of concrete was necessary. The borders are simply composed of three feet of sandy loam, without other mixture. They form the floors of the houses, as well as the slip of ground immediately in front of them, the roots passing from the inner to the outer border through arches as usual. The outer border is now heavily cropped, but it is not intended to crop it after the trees show the slightest sign of wanting more nourishment. Then the borders will be dressed and devoted entirely to the feeding of the peach roots. The inner border is not forked up in the usual way, but allowed to remain as closely consolidated as it usually becomes from men tramping on it. The system of watering pursued here is peculiar, and well worthy of remembrance. The water is gathered from the roof into a large tank in the centre of each house. During heavy rains each tank fills rapidly of course, and then begins the watering. Should it rain for several days at a time, the tanks are daily nearly emptied—the water being poured on to the border-floor. This is done in winter as well as in summer. And the great oaks in the park seem to have suffered no more from heavy waterings in winter than Mr. Temple's peaches.

In the open air there is also, notwithstanding such seasons as the present, which cause the peach to almost perish from cold, a very good example of peach culture: a dividing wall between two parts of the very well-cropped and managed kitchen garden is perfectly covered with rider trees, of which the shoots radiate from about the centre of the wall, like the rays of a star. This wall and others here are thickly studded between each course of brick with galvanised iron studs, to which the trees are trained. This is a simpler and better

system than either nails or wire. Thrust deeply in the wall, when the mortar is soft, they become as firmly imbedded as if part of its substance. They save their cost in a few years, as nails, shreds, wires, &c., are not afterwards required.

THE SOOLYA QUA CUCUMBER.

This was first grown and fruited here. It was sent from the neighbourhood of Foo Chow, in China, by Mr. Temple's brother, manager of the Oriental Bank at that place. Mr. Temple saw it largely cultivated in the neighbourhood of that city only, although his journeys in China were extensive, and not remembering to have seen it in England, sent home some seeds of this monster gourd-like cucumber. It was quickly multiplied at Packington Hall gardens, and soon became spread throughout the land. As yet, however, it is to us only a hothouse curiosity; but the Chinese use it extensively in a boiled state to eat with their rice, and European residents in Foo Chow are said to use it in a variety of ways. This last account gives us more hope of its edible qualities than the statement that it is eaten by the Chinese, for, to say the least, they are not over nice in their food. The curious mixture of vegetable and animal food that one sees in their little shops in the Chinese quarter at San Francisco, affords little proof that what is edible with them would be so with us. It is probable, however, that the Soolya Qua possesses as much value as most other fruits of the gourd tribe, distinguishing this, however, from the melon and true cucumber races.

PLANTS FOR RAILWAY HEDGES.

BY JAMES McNAB.

In many districts of England railway hedges seem to receive much greater attention than many of those planted for the sectional fencing of land. The plant generally employed for railway fences is the white thorn, and a useful plant it is for such purposes, and now contracted for as regularly as the rails themselves. On some of the newly-formed lines the varieties of evergreen hollies ought to be tried, particularly of those portions of a line running through extensive and well-regulated policies in sight of the mansion. In some cases the proprietors may be induced to pay the extra difference of the plants, while the after-keeping will be much the same as the ordinary thorn hedge. In all peaty districts the spruce fir will make an excellent evergreen fence. It will cover more ground than the holly; but in mossy situations this extra land will be found of less value. In sandy places, and particularly those near the seashore, the sea buck-thorn (*Hippophae rhomboidalis*) will be found an admirable substitute for thorns to form hedges. If it should ever be required to make at once an impenetrable live fence, the hornbeam (*Carpinus betulus*) will be found the most suitable, and for this purpose clean-grown sapling plants, six or seven feet in length, ought to be procured. After the ground has been properly trenched and prepared, the plants should be put in, two together, at every ten or twelve inches, according to the thickness or length of the saplings employed, giving one an inclination to the right and the other to the left. After being trod in firmly, commence to plait all together, taking one set of the plants the one way, and the other set contrary, interlacing them at an angle of 45°. It will be necessary to tie them at top with a piece of wire or rope yarn, and also at several points near the bottom, to keep them in position till they adhere to each other. To facilitate the union, although not absolutely necessary, it will be desirable to take a thin cutting off the bark of several, particularly where they approximate. Shortly afterwards they will grow together, and form an impenetrable not-looking fence. From the pressure caused by the plaiting, they will throw out numerous shoots along the stems, which will continue to work in and fill up the interstices. In time the whole length will become an impenetrable mass, all engrafted together, and will bear cutting-in like any other hedge. Numerous other plants will be found in nursery establishments suitable for such purposes, as the hazel, elm, ash, beech, laburnum, &c. Such hedges can be made of any height, depending entirely on the length of the saplings employed. When not in leaf, they will be found extremely ornamental and agreeable to look on, and therefore worthy of encouragement, particularly when standing on a level with the rails.

It should ever be wanted to plant such hedges so as to render them useful as well as ornamental, particularly on lands slightly elevated above a damp surface, in such places willows could be profitably employed, and the annual cuttings taken from them would yield a considerable revenue. Besides, when such plaited hedges are cut for profit, they are more likely to be kept in order than thorn

hedges, particularly when they run through lands which would be profitably employed for the growth of willows. When planting willows for such purposes, they could be inserted either as growing plants or cuttings—the latter will be preferable, provided the strip of ground has been properly prepared for them. They should be placed twelve inches apart, and during the first thinning the strongest shoots should be left for plaiting. After the plaiting had been successfully accomplished, all after shoots could be removed for basket-making purposes.

Ozone.—We have heard of late years so much of the beneficial influence excited by the presence in the air of ozone—Nature's great healing and disinfecting agent, produced hitherto only by electricity or phosphorus, or permanganate of potash—it is well to know that it has been lately discovered by an eminent professor to be evolved profusely in light by strongly-smelling flowers and herbs, also by vegetable essences—as mint, cloves, lavender, lemon, cherry, laurel, and others of a similar kind. The amount of ozone is said to be in proportion to the strength of the fragrance emitted. Flowers destitute of perfume do not develop it.

HARDY PLANTS IN FLOWER ROUND LONDON.

BY OUR OWN REPORTERS.

The following is a recapitulation of plants that have been given in our early lists, but which were still in bloom on the 5th of June. Retrospective lists of this kind, which we intend to give monthly, will enable our readers to ascertain the length of time any particular plant keeps in bloom. Where genera only are given, it should be inferred that all the species of such genera previously given were in bloom at the date just named:—

Abelia	Convolvulus	Iberis	Polygonum
triflora	Cneorum	Pruini	Bistorta
Achilleas	Corydalis	Tenoreana	Brunonian
Aconitums	caponioides and	Ionopsidium	Potentillas
Adonis	var.	stellatum	Fritillaria
Asclepias	lutea	Iris	farinosa
Hippocrateanum	Cotoneasters	Jasminums	luteola
Ethionematum	Crambe	Kalmias	Pyrethrums
Aguga reptans and	Crinum	Lamiums	Quercus
vars.	capense	Lathyrus	Ilex
Anemone	Cyclonia	gibratara	Rhamnuscius
Alchemilla	japonica	Lathyrus	Ribes
heracifolium	Cytisus	pisiformis	rosa
Schenoprasum	praecox	Ledum	Rosa
Anchusa	sempervirens	scoparius	Rubus
italica	Delphiniums	thyrsifolium	Salvia
sempervirens	Dianthus	Lilium	Sambucus
Anemone	Dicentra	immaculatum	Santolina
blanda	Dicentra	Linaris	Spirea
sylvatica	Digitaria	Lithospermums	Saponaria
Antennaria	Dicentrius	Loniceras	calabrica
alpina	Fraxinella	Lunaria	oymoides
diocia and vars.	Diervilia	biemnis	Saxifragas
Antyllis	coreana	Lupinus	Scabiosa
montana	Dodecatheon	Lychnis	amara
Videraria and	Dorycnium	Maclellana	Schizanthus
var.	Eryngium	obovata	biannuus
Antirrhinum	Erigeron	Menziesia	Scladon
Aponozetion	Eriinus	polifolia	asiaticum
distrachyon	alpinus	var.	Sempervivum
Aquilegia	Erodium	Michringia	ciliatum
Artemisia	Euphorbia	mucronatum	monspeliacum

Alton Towers.—The boon afforded to the public by the noble owner of Alton Towers was thoroughly appreciated during the Whitsuntide holidays. On the Monday over 2,000 visitors from Sheffield, Leicester, Derby, Burton, Stafford, &c., enjoyed the beauties of these unrivalled gardens. On Tuesday over 2,000 visitors from Birmingham and the Potteries were favoured, under glorious weather, with a sight of these charming grounds. On Wednesday a very large number visited them from Nottingham; and on Saturday a good number arrived from Manchester, Derby, Burton, &c. The Earl of Shrewsbury's band was in attendance on Monday, Tuesday, and Wednesday. We are happy to say that the first week of the Alton season has passed without there being the slightest cause for Lord Shrewsbury to regret his decision to open the gardens for the season of 1872. Lord Shrewsbury has set apart a portion of the park as a cricket ground, which has been specially prepared and fitted with tents; and can be obtained by visitors for friendly matches on application to the head gardener.

THE SIX OF SPADES.

CHAPTER XVI.

Mr. Oldacre's Story.—The Lady Alice (concluded).

Of course, we kept the secret sacredly; but Phyllis, my wife's sister, and maid to the Lady Alice, seemed to us to know as much as we did. She was ever sounding the Captain's praise, or speaking of his rival in anything but respectful terms, alluding to him as "that galvanised mummy," and expressing her belief that he had been placed as a boy in a petrifying well, and been imprudently taken out before the process was complete. "And though I dare not speak my mind to his lordship," she said, "I have had the pleasure of telling his valet that we don't intend to marry a snow man."

Nevertheless, we heard, to our great unhappiness, that the wedding-day was fixed. The announcement was painful to most of us, but it seemed to have the strongest and the strangest influence upon our sister, Phyllis. She would no longer speak of that which had been her one topic of conversation. She had a nervous manner and an anxious look. Sometimes she would laugh almost hysterically, and sometimes, my wife told me, she would come to her in a paroxysm of grief and tears, for which she would assign no cause.

Then another strange incident happened to me. The evening before our annual county flower show, I had been occupied until it was almost dark, in tying and packing a collection of stove and greenhouse plants, which I was going to exhibit, when, in taking a short cut from the kitchen gardens across the park to my home, I passed over the long walk, which is a continuation, as you know, of the grand terrace, and extends for nearly a mile through our woodland grounds; ten yards from me, but in such earnest conversation that they never heard my steps, I saw two figures, and dim as the light was, I was quite certain that I knew them. I almost ran the rest of my way, and, in a fever of excitement, I whispered to my wife, "Lady Alice has sent me the leaf."

She received my information not only with disbelief, but derision, and next day she sent for her sister Phyllis, to assist her in disbelieving. They said it was simply impossible; that it was one of the housemaids and the underdresser; that Lady Alice was in bed with the toothache (Oh, Phyllis, Phyllis!), and that the Captain was in Windsor Barracks. And when I suggested that as I was there, with a brace of eyes in good working order, and they were not, I must respectfully take leave to differ; then they said, that if I had seen anything, which they did not for a moment believe, I ought to be ashamed of myself spying into people's houses (half-a-mile off) at that time of night, intruding into private walks, &c. I could only plead that up to that hour I had not been aware that after nightfall the duke's park was solemnly given up to the young nobility, paired off, and dying for love.

Finally, after reiterating for the (as nearly as I can guess) forty-second time, that I had seen nothing, they implored, they insisted, that I should never reveal to living creature that which I had seen; and I gave them at last my promise to keep a secret, which nothing upon earth could have tempted me to tell.

The marriage morning came. On the day preceding I had decorated the church as sorrowfully almost as though it had been for her funeral, and at sunrise I had arranged a bouquet; it was composed of Stephanotis, Pancratium, Gardenia, and white rose-buds, which I had mourned over as if for her coffin. "And so," I sighed to myself, "the leaf went, and the lover came; and yet there was neither help nor hope."

The events of the day, as we ascertained afterwards, were these: you will see that they require no commentary.

The party at the castle was to assemble in the library at 11 a.m.; to leave the castle at 11 15, and to meet the Viscount at the church.

At 9 a.m., Lady Alice's favourite cousin, and chief bridesmaid, went to see her, and was met at her dressing-room door by Phyllis, who told the young lady that her mistress had passed a restless night and had just fallen asleep.

At 10 a.m., on a second visit, the cousin was informed by the maid that Lady Alice would rather not see any one until she came down for the marriage.

At 11 a.m., the guests, with the family, met in the library,

At 11.15, a dozen carriages, three of them having four horses, and two with outriders, drew up in front of the castle.

At 11.25, the duke sent a servant to inform the Lady Alice that he hoped she would come down at once.

At 11.30, the servant returned to inform the duke that her ladyship was not to be found!"

Then the duke calmly requested that her ladyship's maid should be sent to him in his morning-room.

And, after a long interval, the report was brought to him, that "her ladyship's maid was not to be found."

Then some one discovered, on Lady Alice's writing-table, a note to her father, the duke. It was, so Phyllis informed us, to this effect: that she had pleaded in vain that she did not love the Viscount—that it could not be right that her whole life should be turned into a lie—that it should be a life of hatred when it might be a life of love—that she was gone with him, who had won her heart, to be his wife—and that she implored her father to forgive her for her mother's sake.

The duke turned very pale, and the duke sighed very heavily, when he had read the note, as well, with his views, he might. His only daughter was travelling as fast as four horses could take her, and had been travelling for six hours as fast as four horses could take her, to marry a younger son.

Then his grace wrote a few lines to the Viscount, who was waiting for his bride.

"The church was decked at even-tide,
The morn was bright and fair,
And priest and bridegroom wait the bride,
But ne'er a bride was there.
They sought her, baith throu' bower and ha'—
The ladye was ne'er seen,
For she's o'er the border, and awa'
Wi' Jock o' Hazeldean."

And once "o'er the border" (I may as well state here), they were married in conformity with Scotland's usage, that they might be man and wife, should pursuers overtake, according to secular law, and subsequently, that they might be so according to the laws of their Church and conscience, by an ordained priest.

Three hours after the Viscount had read his note, all the visitors had left the castle; and in it and around "grim silence held her solitary reign." The only person who passed through our entrance gates with a cheerful countenance (my wife informed me) was my Lord Evelyn. He was just as beaming with mirth and kindness as ever. "Sad business," he said, "Mrs. Oldacre; bad business—disgraceful business," with a broad grin on his face. And then he began to sing something (Mrs. O. continued) about a way they had in the army, or words to that effect.

Yes, they all fled from that stern and stricken duke, as though they were seized with a sudden fear that he was going to bark and bite them. True indeed it was that then, and for many after days, his grace was not good company. He was seen only by those who waited upon him, and their report of his melancholy was very pitiful. What think you happened next?

"My friends," said the good old gardener, with tears in his kind blue eyes, "it pleased God in his goodness, by that great humiliation to change, and, as I believe, to save one of His creatures. Some three weeks after the crisis, the duke left the castle for the first time, and went to the mausoleum. He remained there so long that some of the household were beginning to be alarmed, when he came quietly home, and sent a note to his chaplain, with whom shortly afterwards he had a two hours' interview. We have always thought that he made then a first and full confession. He was from that time, at all events, an altered man. He sent not only his pardon to his daughter, but a fatherly invitation to her old home; and she came with her husband, and with gladness for all our hearts."

This reconciliation, the first fruit of that victory which he had won over self, soon brought its great reward, partly in the fact that the handsome guardsman succeeded against all expectation to the headship of his house—a peerage, with large estates—but chiefly in his daughter's grateful love.

We will leave him, if you please, as I once saw him, and as ever since I have liked best to think of him, plucking an orange for his grandchild, little Alice, from the very tree whereupon grew the leaf.

S. R. H.

(To be continued.)

RHODODENDRONS FOR CUTTING.

WHO that looks on a dazzling mass of Rhododendrons but longs to cut some of the rich and variously-coloured blooms? Among the magnificent hybrids of our garden nearly all colours are found. Scarlets, crimson, bright pinks, and whites are the most effective for cutting. Self-coloured flowers, as a rule, are the most useful for floral arrangements. Too many colours in flower, or leaf either, for that matter, are often fatal to distinct and striking combinations. As well try to paint well with a plurality of colours as to form effective combinations with many-coloured flowers or leaves. This rule of using selves chiefly for cutting for artificial arrangements of flowers is applicable to other plants as well as Rhododendrons. But it is especially important in this family.

There is a wide range of size as well as colour in this distinguished family. From the tiny flowers of such dwarfs as *ciliatum*, *terreneum*, *album*, *Daphneoides*, *gemmiferum*, *fragrans*, *myrtifolium*, and others, to the regal *grandeur* of *arboreum* and its hybrids, we have a range of size such as hardly any other class of plants affords. The smallest are less than the pretty *Azalea amena*, and the largest such that a single truss is furnishing for a flower vase. No bouquet can be too neat to be partially formed with Rhododendron. No room, nor church, nor hall, nor theatre, can be too large to be illuminated by their superb trusses. The flowers stand in water well if carefully gathered. They must not on any account be heaped together, as many of them are partially viscid outside, causing them to stick more or less to each other. They are also easily bruised, and soon flag unless placed instantly in water. The greater proportion of Rhododendrons are most suitable for large arrangements of cut flowers. A truss or two is often most effective as a central piece to other combinations. For instance, I have seen a large vase admirably furnished thus: a fringe of *Caladium Chantini* leaves on a blue or green vase, then six *Calla* *ethiopica* flowers, and finally the raised centre furnished with three large trusses of *Rhododendron arboreum* and a few of its leaves. High-coloured Rhododendrons and white lila likewise look well together; or pale Rhododendrons and the highest-coloured lilac. There are comparatively few Rhododendrons fit for bouquets. For this purpose, single blossoms of the choicest colour and sweetest fragrance are employed. Mounted like azaleas, they stand as well or better. Such sorts as *formosum*, *fragrantissimum*, *jasminiformum*, and *ciliatum*, are admirably adapted for bouquets; while single flowers of the glowing scarlets, pinks, and whites form capital centres or building material, if used sparingly, and well padded with moss or other material, so as to avoid crushing or overcrowding.

But the place for the general mass of Rhododendrons as cut flowers is at some distance from the eye. As centre-pieces for large dinner-tables or public rooms few, if any, cut flowers can equal Rhododendrons in massiveness and magnificence. But Rhododendrons, like not a few other flowers, are much better surrounded by their own foliage; in some species the leaves are very fine.—Field.

Californian Wines.—It is certain, says the *San Francisco Press*, that the sunny climate of California produces wines surpassing those of France and Germany; it is also true, says the same authority, that the uniformity of quality, and the greater yield of our vines, year after year alike, and no such thing as failure, enables us to produce wine cheaper than in Europe. France wants lands for the staff of life; and it is predicted that ere twenty years have passed, it will be a national question, if it would not be policy to turn uncertain vineyards into wheat-growing lands, and to buy better and cheaper wines from California.

Killing Weeds on Walks (Vitriol v. Hand Picking).—*Aprios* of killing weeds on walks in the best and cheapest manner, I think your correspondent "R. B., Leamington" (p. 612) is but indifferently acquainted with the results arising from the use of oil of vitriol or its nature. In the first place, advising it to be mixed in a watering can is evidently a mistake, as its chemical properties would rapidly destroy the solder and render the can useless. As regards expense, I have given it a lengthened trial here, and I find it will kill weeds when mixed in the proportion of one part of vitriol to six of water, and even then only those that are saturated with the solution, whilst those that escape with only a slight sprinkling will not die. In all cases where I have used a weaker solution, the weeds have in three weeks been as green and rampant as ever. The proportional expense is as eight to one compared with hand weeding. What would cost £12 for hand weeding would amount to about £100 where the acid is used, to do the thing at all satisfactory.—CHARLES DENNIS, Southwark Park.

THE FLOWER GARDEN.

PRIMULA JAPONICA.

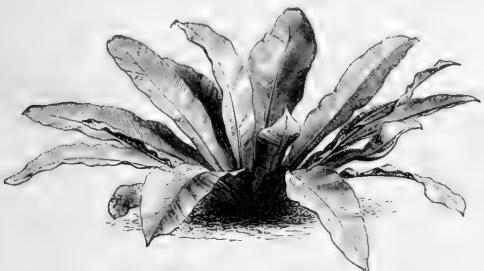

This lovely plant, a favourite with everybody, only reveals one whorl on each stalk at a time. Some have been disappointed at this; expecting it to unfold all its flowers at once. But it could hardly do so, as it goes on growing and flowering as it grows. The brilliant representation in the *Florist* for June 1871, is, therefore, not likely to be realised. In one sense this is all the better, as it prolongs the blooming period. The usual number of whorls on strong plants is about six deep, and the number of flowers in each whorl ranges from eight to twenty-four. It is a glorious plant and seeds freely, so that our outside beds and borders will soon be enlivened by this brilliant stranger, which at a distance looks like a bright pyramidal variety of *Phlox Drummondii*. As a pot plant it is superb, and has a fine effect as a star in a line of Chinese Primulas, double and single. In such position it would also be well placed for cross breeding. There are already six varieties of it offered in as many different colours; and doubtless within a few years the *P. japonica* strain will be as useful and highly prized, and even more admired, from the fact of their hardiness, than the Chinese.

D. T. F.

THE BIRD'S-NEST FERN.

(ASPLENIUM NIDUS-AVIS.)

THIS is a remarkable fern, which may be placed out of doors in the garden in summer, from early in June to October; but it is not sufficiently vigorous or hardy to be generally recommended for this purpose. The leaves are rather broad, pointed, and undulating,

Asplenium Nidus-avis.

nearly three feet long, and form roundish, spreading, nest-like tufts. It is a favourite subject in places where large collections of tropical ferns are grown. It succeeds perfectly in a temperature of from 45° to 50° in winter, and is readily increased by means of spores.

A SIGN OF THE TIMES.

THERE are signs that the tyrannous and unmeaning formality of our gardens is becoming irksome even to those whom the common bedding system and its often equally formal surroundings have been wont to enchant. We find, for instance, the following leading article in an influential provincial paper, the *Birmingham Morning News*:

"Our fathers had not learned the art of grafting roses upon broomsticks, nor would they have admired little bunches of foliage and flowers perched up on the top of tall sticks, and planted at regular intervals. With them at least, a flower was held to be part of a plant or a tree, and they delighted to see it grow naturally. They did not look upon flowers merely as 'specimens,' to be forced into an undue size, and then gathered and stuck into a bottle. Nowadays when anyone is told that such and such a person is a great gardener, the first question that is asked is, 'Has he much glass?' The great gardeners of the present day are those who have much glass. The great gardeners of the past day were those who grew the greatest number of trees having blossoms in the open air; trees that could stand a good downright English winter; trees that could hold their own during a frost, and then when the frost was over, and the warm weather had arrived, would put out their brilliant foliage, and their glorious clusters of white and purple, and scarlet, and gold flowers. Those were the men who made our towns so full of beauty in the spring, and surrounded them with groves of

laburnum and lilac, of pink hawthorn and stately chestnuts, and many another flower-bearing tree. The modern garden is a desert for three-fourths of the year, and during the other quarter shows, for the most part, ill-arranged bolts of glaring colour. Thousands of 'bedding-out plants' are crammed together to get a line of scarlet, which is succeeded by a line of blue, and that followed by a line of white; or the ingenious combination is hoisted into a gardener's notion of a curve, and so we have our ribbon borders, over which it is supposed we ought to exult with delight. The old garden was at hardly any time destitute of flowers. It had flowers for each season of the year, growing in constant succession, and, best of all, it had that glory of our island, the tree bearing flowers. In these trees there is always a good proportion between the leaves and the flowers. The gardener cannot nip off the leaves of a lilac or a laburnum, and make the tormented thing grow flowers alone. He cannot play tricks of that kind with a horse chestnut, nor twine its branches round a wire frame. Nature does have her own way with those larger growths, and they escape the degradation which befalls every plant that can be got into a hothouse; and there is more true beauty in almost any spray of leafage growing wild than in any carefully fostered collection of botanical monstrosities growing tame. Before the last acre of garden ground is surrendered to our modern gardener, we do hope that there will arise a reaction against the modern system, so that, at the least, if the ribbon border still flourishes, the blossoming trees may be permitted to flourish also."

Statements such as these call for a few remarks. It is a mistake to suppose that our forefathers had any advantage over us in matters of taste. They did not grow broomstick roses, because they did not know how; but they clipped the cypress and the yew into the shape of a coffee-pot or a bear, and gloated over the melancholy result. Living in a day when "free nature's grace" was much more evident than now, they fell victims to formality. The wild wood was near, and was often picturesque, and it was so novel to see the conventional patterns of the decorative artist wrought out upon the grounds. From our fathers we inherit the stupid notion that it is not only pleasing but necessary to run bits of architecture into the garden, and to otherwise violate what ought in nearly all cases to be the foreground of our garden pictures, by stamping it with a huge edition of a pattern, which may perhaps be found on the back of the fire-shovel. This demonstrably false dogma has been handed down to us by everybody who has written on landscape gardening. No! we have nothing to learn by going back. Our fathers as gardeners had one inestimable boon—an abundant variety of spring and early summer flowering plants. This anybody may see who looks into Parkinson or any other old book on gardening from before Shakespeare's time to the days of John Abercromby. We may well imitate them in this respect, but there stop. We have advantages tenfold greater than theirs, and should produce a result immeasurably higher, from the point of view either of art or nature. The gardener is naturally the scapegoat of the Birmingham editor, but he is not the person to blame. Most gardeners of our acquaintance have a real love for plants, and would gladly get out of the exaggerations of the bedding system if their employers would permit them. The bedding system, pure and simple, is the greatest labour that ever fell upon gardeners. Under it they have to devote nearly all their energies and time to the production of effects, which, however attractive, disappear almost as quickly as the flashes of an illumination. Of course there is, as a rule, little time or strength left wherewith to minister to the more legitimate objects of a gardener's care, and to extensive planting and happy arrangement of trees, shrubs, and hardy flowers. Any one of these may, for an hour's wise and gentle attention in happily placing and planting it, thank us with green shade and grateful blossoms for a hundred years. No, it is the master who is to blame. He, an educated being, annually visiting or traversing some portion of the earth, from which he can hardly fail to glean a fuller notion of the boundless variety and beauty of the vegetable world than from a ribbon border, finds fault with his gardener for not out-blazing some neighbour, happy in the glory of bedding out, what is commonly and very appropriately called "stuff," to the extent of seventy thousand plants. He it is, who, visiting the Academy every year, and perhaps thinking nothing of a few hundreds, or it may be a few thousands, for a representation in pigments of some fair

bit of tree and earth beauty never thinks of doing what is so easily done—form living pictures of the stateliest and loveliest tree-life. The treasures of the vegetable world brought round his home are probably limited to a barrowful of pelargonium cuttings, solicited from a neighbour richer than himself in such treasures. The result of course is one in which no man or woman of taste or feeling can find the least instruction or real beauty. Even those who think they enjoy it have no notion of how much true pleasure is lost by confining themselves to such few plants as furnish some desired colour. As for the effect on the general public the result is simply deplorable. They may stare at the border; but who is taught anything by it? Who is led to do any really good work in gardening thereby? On the contrary, it degrades the noble and gentle art, and consequently all devoted to it, in a manner to be deplored. But the system is not now in need of being either discussed or condemned. What is wanted by both amateurs and gardeners is to know how to mend matters, not by abolishing the too common system, but by modifying it, and by devoting ourselves more and more to the many other ways in which a garden may be beautified. To forward this good end in every way will henceforward be one of the main objects of THE GARDEN.

BUPHTHALMUM SPECIOSUM.

A HARDY, distinct, and vigorous herbaceous plant, the stems of which are stout, very slightly branching, and about four feet high, with broad leaves mostly clustered around the base of the plant, the lower ones falling gracefully towards the earth. The flowers which have a red or purple disk and yellow rays, are more than two inches

Buphtalmum speciosum.

across, and are borne in the axis of the upper leaves, and appear in June, July, or August, according to the season. The plant seldom flowers well before the third year. It is of easy culture in any soil, is increased by division in autumn, winter, or spring, and is best fitted for association with the more vigorous herbaceous plants in rough and half-wild places.

FUCHSIAS IN THE OPEN AIR.

In our race after novelties we too frequently forget old favourites which get pushed to the wall to make room for new comers of less value. This is particularly the case with Fuchsias, and the consequence is that many which make splendid border plants are rarely seen. Passing through a nobleman's garden very recently I saw whole troops of those robust and nearly hardy Fuchsias, Ricartoni and corallina, the former a compact free-growing variety which only yields to the most severe frost, and the latter an admirable border, shrubby or wall plant, which will cover a large area in a short time, and yield armfuls of its intense corn-coloured flowers for cutting quite late in the autumn. I was so pleased with them that I begged some plants of each, and intend to grow them on to mix with chrysanthemums in November. F. Ricartoni was raised at Riccarton, near Edinburgh, and in favourable situations, as, for instance, in the south or west of England, or near the seashore, it will grow into large bushes, make hard woody stems, and rarely succumb to the weather, unless there is some 15° of frost, and even then, if it should be killed to the ground, it will throw up the following spring a whole forest of shoots from the roots. Some

years ago, when calling upon the gardener at Baron Hill, near Beaumaris, I entered the garden in the dusk of the evening, and passing along the terrace I described in the distance a huge bush, some twelve or fourteen feet high and nearly as much in diameter, feathered to the ground with glowing crimson. The sight was so unusual that for a time I could not conceive what it was, until approaching nearer I found it was a plant of the Fuchsia in question, studded with thousands of its brilliant flowers. The stem of this plant could not be less than a man's leg, and the side branches as thick as one's arm. It had grown unscathed for years, and at the following severe winter of 1861 it was killed to the ground. In the cottage gardens in Anglesey, especially along the Menai Straits, bushes four to six feet high are quite common, and such a thing as protection is never thought of. Here, in the Midlands, I could not expect such results. I could insure the growth, but without protection the plants would be killed to the ground every season. If, however, I took the trouble to protect the plants through the winter—that is if I threw a barrow-load of leaf mould, littery dung, or even ashes over the roots, and then bound the branches together and coated them with a good thickness of thatch, making it quite waterproof—no doubt, not only this Fuchsia, but many other varieties might be had in the form of bushes or lawn specimens through the summer and autumn. No plant is better suited to cover a wall or the end of a cottage than *F. corallina*. Planted in good soil it will make six feet of growth in the season, and that growth may be readily protected by a waterproof covering of thatch, and some litter over the roots and around the stem. There are many other kinds of Fuchsia equally well suited for outdoor cultivation, but in my mania for scarlet and variegated Pelargoniums we have forgotten the graceful "Crimson Drop." All that Fuchsias require to insure perfect growth is a deep rich soil, and plenty of liquid manure in hot dry weather. So planted they will grow with the luxuriance of a common dock, and once established, with the protection I have recommended through the winter, there will be a splendid bed for a lifetime. The most suitable varieties for outdoor cultivation and bedding are the strong-growing ones, but for training upon walls, trellises, or pillars some of the more attenuated growers may be used, but of course, they will require careful and regular tying. Then the floral branches will hang in graceful folds, but untrained they will soon become very ragged. One of the prettiest sights in the way of Fuchsia-growing I ever saw was in a glazed narrow arcade, connecting a family residence with the conservatory and forcing houses. The arcade was about six feet wide. Up the back Fuchsias of various kinds and colours were trained with clear stems, but when they came to the roof, which was a span, they were allowed to branch and cover it, which they did most effectually. To see thousands of flowers, varying in colour from bright scarlet and crimson to white, some with violet corollas, some with white, and others with scarlet, mauve striped, &c., all intermingled, forming a mass of rich and elegant natural colouring, was indeed a grand sight. Those who are seeking for handsome climbers for conservatory decoration will do well not to forget the Fuchsias. Properly planted, and kept clean from red spider and thrip, they will find them beautiful for many months in the year, and, once established, of little trouble. I have had *Venus de Medici*, which makes a very effective climber, grow twelve feet in a season, and even so bad a grower as the double-flowered Sir Colin Campbell, eight feet in the year.

Z.

Lychnis Lagascae.—I obtained last spring a strong healthy plant of this beautiful Lychnis, which I planted in a piece of rock-work, properly made in the manner described in "Alpine Flowers," and in which it appeared to thrive satisfactorily, flowering profusely for several weeks in the summer. The foliage on the approach of winter withered off, as was to be expected, but no trace of fresh growth has appeared with the spring; nothing visible has yet come above ground, and I presume the plant must have perished in the winter. It is rather an expensive plant to buy, and before ordering another, I should feel obliged if you would inform me whether it is so thoroughly hardy as to be exposed without risk out of doors in winter. A colony of worms had evidently established itself in the neighbourhood, which possibly may have caused the mischief. Will you kindly inform me how I can best get rid of these worms? I thought of applying clear lime-water to bring them out, but fear it may be injurious to the plants. This place is at an elevation of just over six hundred feet above sea level, open to the south.—W. B. R. —[We believe the Lychnis to be perfectly hardy; lime-water will rid you of the worms and do no harm to plants.]

Allosorus crispus and other British Ferns.—In reply to Mr. Trench (p. 478), who states that this fern does not thrive well with him, I beg to say that I cultivate a number of hardy British ferns, and

I pursue one uniform plan with all of them. I procure them from their native habitats, and treat them, as nearly as possible, according to their natural requirements. The *Allotropa crispa* does well with me. I dig it up with a part of the earth about it which it has been growing; if on a piece of rock or stone, which sometimes happens, I lift the whole if I can, and transfer it to my greenhouse, sometimes placing it in a pot, and at others on the top of a sandstone, with a little more earth of a sandy, porous character about it, giving just enough of water to keep it healthy, and it invariably does well. It, however, requires a little shade, and very little root moisture. I have several of the more fragile sorts of ferns growing outside, entirely shaded by bushes and trees. Such as I procure from the interstices of rocks, caves, gullies, and waterfalls, I treat thus, and the rain, as it descends through the branches, falls on them in the form of "spray," resembling what they receive in their natural habitats. It is worth observing, that I generally find them in a north-eastern exposure, and I plant them in a like situation. I protect several from snails, &c. *Hymenophyllum* require the same treatment as the *Trichomanes*, viz., moderate heat, a close atmosphere, shade, and a porous soil. They do very well covered with bell-glasses, or kept in a case. *Polypodium Dryopteris* does uncommonly well with me; it is an elegant fern. I have one in a pot edged with the *Allotropa crispa*, a combination which looks beautiful when covered with a bell-glass. About three weeks ago I came upon a fine plant of *Allotropa crispa*, about four hundred feet above the sea, embedded in a heap of stones and earth; in fact, it was adhering to a sandstone. The fronds are about four inches in length; but the general altitude is much higher. I plant high in the pot or ground, and on no account do I ever mix lime with the mould in planting.—S. K. ANDERSON, *Duncon Garden, Dunfermline, N.B.*

Lawns of Savin Juniper.—At Odessa the climate in summer is often torrid, the soil is dusty, and dries up to a great depth. Lawns are impossible in these light and burning sands. Monsieur Cortazzi, a rich merchant, who possesses a charming villa on the scashore near Odessa, has found a most ingenious remedy for this difficulty, which I have only seen tried by him. A great part of his lawns are of the two varieties of Savin Juniper—*J. Sabina cupressifolia* and *J. S. tamariifolia*. These shrubs are planted when quite young very near each other; they are laid down and trampled on, and each year they are rolled; they are thus forced to creep uniformly on the ground, and they form, during the greatest droughts, the most beautiful dark-green lawns imaginable.—*Ed. André*, in "*l'Illustration Horticole*."

On Planting Aster.—I was walking through a nursery the other day and I saw two men preparing beds for Aster on a piece of soil that had been recently dug. They had formed eight beds, about four feet wide, and I should think they were fifteen yards long. Paths were dug between each bed about six inches deep, the soil from which was put on the bed and then raked level. Each had a piece of stick, eight inches long, to measure the distances and to make the holes. This was done all over the bed; and then they filled the holes up with water, which to me seems an expensive operation. Will some of your readers kindly tell me what advantage this has over the usual plan of planting?—AN AMATEUR, Cambridge.

Cheiranthus Marshallii.—Would any of your readers inform me if they have ever succeeded in seeding this beautiful spring flowering perennial? I have tried it under various conditions, but without success. It may be urged that seeding is of little moment, because it can be so easily increased by means of cuttings. I readily admit that, but if it could be got to seed perchance some additional colours might be obtained; and, what would be a matter of great importance, some that would flower earlier than the parent. There is no hardy perennial that carries in the spring such an effective mass of orange-yellow colour as does this Cheiranthus, but as the flowers do not expand before the end of April, it is too late for actual spring gardening. It is, however, most useful for cut flowers, as they are deliciously scented. The old pale yellow variety, *C. ochroleucus*, is I find much more common, but it is scarcely so effective as Marshallii; both, however, are deserving of a prominent place in every garden where a fondness for spring flowers prevails.—A. D.

The Wild Garden.—I think it would be delightful to exchange wild flowers with each other. The woods in my neighbourhood contain various varieties, none of which I planted in my wild garden and house with greater advantage than *Dentaria bulbifera*, which abounds in a wood here. One great advantage attending the planting of rare wild flowers, is being able to study them in their various stages of growth. Nothing is more provoking than making an excursion to secure some floral gem and finding it out of blossom; the disappointment ceases, however, if the seeds are secured instead, from which can be formed a small colony in our own gardens. In

Dorsetshire, two summers ago, I found a *Helianthemum* in seed, the leaves of which did not appear to be those of *vulgare*. I secured some seeds, and sowed them last summer; they were scarcely ripe, but one has developed into a plant, and I am anxiously awaiting its blooming to determine its species. I should be delighted to have a few roots of *Epilobium angustifolium*, as it is a most lovely flower.—M. P., *Botany Cottage, Kent.*

Green Wild Flowers.—Lovers of native plants have been enthusiastic in describing the rich and varied tints of colour found in some of our spring flowers, but seem to have overlooked the many interesting and beautiful subjects that bear greenish-coloured blossoms. One of the prettiest and most delicate of these is the *Moschatella*, which is found abundantly in the hedgerows and copes of the Surrey hills, in the steep lanes of Kent, and elsewhere. In moist, shady situations, its green-tinted flowers, raised above its leaves of a darker green, are so beautiful that it seems a mystery why it has been so inappropriately named. First among spring flowers, however, we have the *Daphne Laureola*, a graceful little shrub that bears clusters of green blossoms. Perhaps the most lovely of all green-flowering plants, however, is the *Hebe Paris* (*Paris quadrifolia*), which is remarkably beautiful in all its parts. Although not very common, I have found it this spring growing abundantly in a wood in Hertfordshire. The flowers, as they hang back their long thin sepals, look like some curious foreign spider or "daddy long-legs." Again, we have the *Spurges*, many of which are of a fine green colour, and others of a yellowish green, very interesting to examine though perhaps rather puzzling to beginners. There is, moreover, the Dog's Mercury, with its male and female flowers; and several kinds of trees also furnish us with good examples of beauty in the shape of green flowers.—M. A. D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Banksian Roses (see p. 608).—I saw another glorious show of Banksian roses the other day at Hill Hall, near Brossley. They covered the face of the house to the apex, thirty-four feet high, and went, I don't know how far over the roof. What glorious ornaments for all high walls, houses, &c.—W. R.

Aralia japonica.—In the London parks this fine *Aralia*, commonly, but wrongly, called A. Sieboldii, has proved a very hardy plant in various localities. I noticed a mass of it in the Regent's Park the other day, near the southern entrance to the park. It looked quite healthy, and seemed to have remained out of doors all winter unprotected. As a fine-leaved hardy shrub it is far from sufficiently known.—H.

Wall Plants.—In Coventry the other day I saw an old gate pillar crested with a fresh and bloom-whitened tuft of the *Mossy Saxifrage*. It was quite at home in company with that old wall-hunter, the *Stonecrop*, thus proving it a good wall plant. I excluded the *Mossy Saxifrages* from my lists of wall plants in "Hardy Flowers," thinking they could not exist on walls. Seed of the *Mossy Saxifrages* should be sown where there is a little soil, some decayed moss, or half rotten mossy chinks, in which to root.—W. R.

Viola cornuta.—This *Viola* is now as lovely in our gardens as it soon will be on many a high mountain pasture in its native land, long covered by the snow. Few plants are so useful in the spring and summer garden. A belt of it, two or three inches apart, six hundred feet long, was one of the most striking things I have seen. The effect was very charming when the plants were viewed closely, or at a distance.—W. R.

Clematis montana.—This valuable hardy climber, and its fine variety, *C. paniculata*, are not uncommonly seen on walls in our gardens hacked about and trained after the orthodox fashion, but they are not seen to anything like the best advantage in this way. If planted so that they may trail at will over boulders, old stumps, small dead trees, the walls of sunken fountains, &c., they will form a most charming feature in the garden in May, and that without any aid from the pruner or trainer.—S.

The Germander Speedwell (*Veronica Chamœdrys*).—This little wild plant, which forms such bright, soft masses of blue in hedge-rows and by roadsides, is better worthy of culture in the spring garden than a good many exotics grown therein. It is a perennial, and also well suited for a place in the rougher parts of the rock-garden, and for rockwork, rough sunny banks, &c.—W.

Mildewed Roses.—I saw a Marchioness Rose under glass, and can perhaps give you a good hint (see p. 608) on the word "mildew." It was in full leaf, not yet four years old; it covers an upright trellis (which has light on both sides), fourteen feet by six feet, and produced upwards of three hundred perfect flowers within the last month, as many as fifty being gathered and counted one morning. It is an evergreen Rose in the house, its last year's leaves having not yet all fallen. Its treatment principally consists in cutting away all the old stems, and still leaving a few alternate new ones, and taking care of those that are strong and healthy, so as to make them in the autumn stand up to its appearance, as it often does, it is immediately washed off with a sponge and soft soap water, made with three or four ounces of soft soap to a gallon of water. This is quite as effectual as sulphur, and leaves no marks. The soft soap should always be dissolved in cold water, a hint for which I have to thank Mr. Tillary.—WILLIAM TAYLOR, *Longflet.*

The Pansy.—What a glorious mass of early spring flowers the Pansy produces when grown in a suitable soil and situation! I have here, at the present time, a large border, 12 ft. by 3 ft., containing nothing but the Pansy, and in April and May to find a scene enjoyment equal to that in the winter rose-beds. On looking at them on a bright sunny day, all their smiling faces looking at you, and their odour is strongest at that time. This border was sown some five or six years ago, with the seeds of some of the best Belgian fancy varieties, mixed with seeds of good named sorts. Every year since, in summer, after the Pansies have done flowering, asters, stocks, and gladioli have been planted, and the border has been dressed with manure, and the beds carpeted with the flowers. I have been enabled to select some good bedding kinds of new colours from the immense quantity of seedlings grown every spring in this border. Every autumn, a top-dressing of rich rotten manure is given, which mixes amongst the seedlings and keeps them vigorous.—WILLIAM TILLEY, *Welbeck.*

A SKETCH OF THE LAWS, COURTS, AND OFFICIALS
OF THE MEDIEVAL FORESTS OF ENGLAND.

BY E. S. ROOSCE, ESQ., BARRISTER-AT-LAW.

AMONG the odd features of this transitional age, the earnestness which land reformers display in preserving commons and forests in their primitive condition is very marked—men who at every opportunity that presents itself endeavour to show that new social movements necessitate new tenures and divisions of land, yet move heaven and earth to revive old privileges and old forms of procedure, in order to prevent certain kinds of property from losing any of their ancient and almost forgotten attributes. The latest, and one may almost say the most remarkable instance of this spirit of renovation, was the assembling of the forgotten though not quite obsolete Court of Attachments of Epping Forest on the 26th of last September; a singular attempt to use legal machinery, which our ancestors employed chiefly to crush the lower classes, for the benefit of those very persons who in former days suffered most from its powers. And since this court was held much has been heard about various forestal courts, which are being revived at the instigation of the Corporation of London, for the object of preserving Epping Forest as a place of public amusement for ever; but shortly we may hope to see this end attained by an Act of Parliament.* It may be seasonable, therefore, to give a short sketch of the forestal laws and customs of the Middle Ages, the groundwork of the present game laws, which will soon be known only to the black-letter lawyer and the antiquary.

If the truth were known, we should probably find that most people form their notions of a forest and forest life from the opening scene in "Ivanhoe," where Gurnil, the swineherd, is discovered among the green glades of Sherwood Forest, and from those peeps of outlaws' life which Scott gives us in the rude hut of Friar Tuck and the sylvan throne of Robin Hood, and that the elaborate and severe system by which the sixty-eight English forests were ruled is practically unknown.

Old writers define a forest as "a certain territory or circuit of woody grounds and pastures, known in its bounds and privileges for the peaceable being and abiding of wild beasts and fowls of forest chase and warren, to be under the king's protection for his princely delight;" and this "circuit of woody ground" was surrounded by clear spaces called "purfleus," also within the jurisdiction of the forestal authorities, and could contain, as we see above, chases, parks, and warrens; for it was, to quote again the quaint language of the mediæval commentators, "the highest franchise of princely pleasure," watched over by special officers, who administered special laws in their own courts. A chase, on the contrary, when separated from a forest, was under the common law only; so also was a park or inclosed space, and a warren, which, however, was a home only for hares, conies, pheasants, and partridges, and not for larger game. And to perceive how important a part forests and hunting formed in the social system of our ancestors, we have but to glance at the Statute Book, which is full of laws upon the subject, most of them based upon the *Carta de Foresta*, passed in the ninth year of the reign of Henry III., which consolidated, or rather codified, the various unwritten rules and customs by which the forests had before been governed, and formed a less though still extremely stringent measure for the guidance of the tyrannical foresters; for, as a modern writer has it, there was—

"A noose for his neck who a snare should contrive;
Who skinned a dead buck was himself skinn'd alive."

The laws subsequent to this charter generally explain or modify it, or endeavour to restrain the rapacity and brutality of the keepers; while the most modern Acts have usually been passed to abolish the forestal jurisdiction, to destroy the forests themselves, and to vest the management of those which are allowed to exist in the Chief Commissioner of Woods and Forests.

But to pass on to the actual laws and officers of the forest, it may be stated that the lowest of the actual tribunals for the administration of forestal justice was the Court of Attachment, held every forty days, presided over by the Verderers, and very similar in its functions to a modern grand jury. When the judges had assembled, the Foresters and Rangers appeared and made their presentations *de viridi et venatione* as to the state of the "vert" and venison of the forest; the "vert" comprising in forestal language "hant bois," "sous bois," and "special vert" (pear, crab apples, and hawthorns), in fact, every green leaf, great or small, for not only must the deer have tender shoots to feed upon, and a refuge from the wind and sun, but it was also "a pleasant prospect for a prince to see stately trees which grace the forest."[†]

When all the presentations had been given, the Verderers proceeded to hear evidence as to the truth of the facts which they alleged, and in every instance when the case appeared to be *prima facie* true, it was referred for more complete investigation to the tribunal which stood next in order—the Court of Swainmote. Here, also, the Verderers were the judges, but assisted by a jury consisting of those who held lands or lard within the bounds of the forest—men of substance—and of certain of the forestal officials. The number was not fixed, but it was usually eighteen, twenty, or twenty-four. It assembled three times in a year, in June fifteen days before the Feast of St. John the Baptist, fifteen days before Michaelmas, and again about the Feast of St. Martin, in the winter, and there was scarcely an offence against actual woodland law which was not within its cognizance; the slayer of deer, the stealer of herons' eggs, the burner of gorse, the man who pastured his goats for too long a time on one piece of green sward, and the tyrannical forestor especially, were

each and all amenable to its jurisdiction. Theoretically, every sentence upon any unfortunate offender which was pronounced by this subordinate court required a ratification by the High Forestal Court of Appeal, the Justice Seat. This was the court of the Chief Justice in Eyre of the Forest, who was a man of great knowledge of all the law connected with forests and with the chase.* The first ceremony which took place when this high official had opened his court was an assembling of all the foresters, each of whom, humbly kneeling, delivered up to the justice his horn, who thereupon delivered it again to the suppliant upon the payment of a fixed fine. The jurisdiction of this high official was very extensive, embracing not only grants of licence to hunt,† appeals from the Court of Swainmote and direct offences—eighty-four in number—against positive forestal laws, but also indirect crimes, such as speaking disrespectfully of any court or office, a tymatical jurisdiction which the judge did not fail to use, as the following example will sufficiently show.

In the year 1632, a certain Sir Charles Howard was charged before the Court of Swainmote with cutting timber in an unlawful manner. Like many who nowadays make use of, or come within the power of the law, he was much dissatisfied with its operation, or with those who administered it. It may be rightly, or perhaps with the same amount of reason that Shelley had, when he wrote his well-known lines to Lord Eldon, and painted that venerable Tory as the most heartless of villains; at any rate, he said openly that things were carried against him with a high hand, and that his case should be heard of in another place. Thereupon he was brought before the Justice Seat, was fined £100, and, being unable or unwilling to pay this sum, was committed to prison. And this happened long after the days when the administration of forestal law in its severest form had passed away.

Having thus briefly sketched the forestal courts, we will shortly mention the officials who administered the law, or acted, so to speak, as the police and guardians of the forest and its inmates. Highest in rank comes the Justicarius Itinerans Foresta circa Trentam, the judge of whom we have just spoken. The first was appointed by Henry II., A.D. 1184; and the last who filled this post, one much coveted in the Middle Ages, was the Earl of Holland in the reign of Charles I. There was also another chief justice for the parts beyond the Trent, but he was a man celebrated rather for his high rank than for his knowledge of the laws; indeed, it was almost an honorary post, and shows very clearly how little the authority of the kings of England was actually respected among the almost independent nobles of the North, each of whom governed his own domains, whether forest or village or cultivated land, much after his own will. Next was an official whose duties were light, and whose rank also seems to have been almost honorary—the chief warden of the forest. He was succeeded by the verderers, men of standing chosen by the county, who, as we have seen, chiefly acted as judges in the forestal courts; regards, twelve in number, whose principal duty was to inspect the forest and its purfleus, and take note of damage to the wood and of encroachments from without. But these are not all of the rulers of the forest. The foresters had more actual power than any we have yet enumerated; they held their post for life, or during their good behaviour, which often meant until the king saw fit to substitute for one baron another who had recommended himself by some courtly or knightly service. It was not only a personal office, but one which could be held in fee, that is, attached to land or to a barony, even in right of a wife, and in the former case could be forfeited, as happened, to take one instance only, to Roger Bigot, Earl of Norfolk, and forester of the Forest of Pickering. But when we discover the power which belonged to these foresters, the elaborate machinery of the courts already described seems little better than a mockery, for they could summarily arrest any offender against the laws of the forest, then and there imprison him in the deepest dungeons of their strongest castle, with the knowledge only of their lawless servants, and then the unfortunate man could not be released except by a special writ from the King, or the Chief Justice in Eyre, before whom he was compelled to appear. It is not wonderful, therefore, that these forest laws appeared to our poorer ancestors solely as instruments to aid the great barons in schemes of robbery or revenge.

At length, in the reign of Edward III., these foresters carried things with so high a hand that their duties became the subject of further enactments; and to curb their power the statute of 1 Edw. III., c. 8, was passed, which defined the four occasions when a man was liable to summary arrest. These were, if he was taken in "manner" or "dogdray," that is, if his hound was actually dragging off a wounded animal; when hidden with bow or greyhound behind a tree, with his quarry in sight.

The subordinate officials, whom it suffices merely to mention, were the Riding Forester, who rode before the king should he hunt in the forest; the Rangers and Baillifs of walks, who may be best described as under-keepers of the game; and the Woodwards and Agistors, who, as their names respectively show, were the guardians of the trees and the pasture in and around the forest.

Such is a brief sketch of the elaborate machinery by which our ancestral nobles governed the inhabitants of the forests and preserved their game; and all these laws and rules, and the minor matters connected with them, form an important feature in the social history of mediæval England, and deserve a more careful study than is usually allotted to them. But most strange it is to see, at a time when there is great difficulty in retaining even the very remnants of these laws, an endeavour to revive in a suburban hotel those ancient courts once held in wooded glades, and whose very names recall the great forests and woods of England.—*Fild.*

* The Epping Forest Amendment Act, 1872. There is also a Bill introduced by the Corporation of London with the same object.

ASPECTS OF VEGETATION.

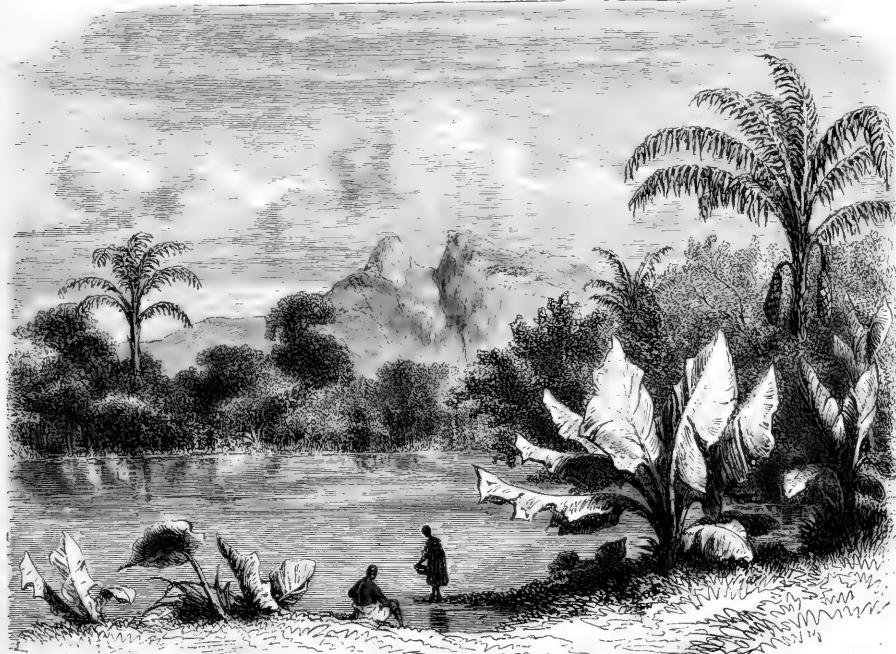

RIVER-BANK SCENERY IN MADAGASCAR.

MADAGASCAR, the coast surface of which is for the most part flat, has an interior richly wooded and mountainous, with here and there lakes, rivers, and well-watered valleys. To the Rev. Mr. Ellis we are indebted for the following account of river-bank scenery in that island:—

"The morning was fine and cool, the water smooth, and the scenery on both sides exhibited new forms of vegetation in great luxuriance. The country on the right was flat, in many parts planted with sugar cane. The banks on the opposite side were high and steep. Here the singularly rich and stately rofia palm, *Sagus rufia*, was so abundant and conspicuous as to impart something of the character of its own graceful form to the surrounding scenery. While thus sailing smoothly

Lindley have thus spoken of *A. Wallachii*:—‘One of the finest plants ever introduced. And when loaded with its magnificent flowers, we think nothing can exceed its grandeur. I had seen a good-sized plant growing freely at Mauritius, but here it was in its native home, luxuriating on the banks of the stream, its trunk a foot in diameter, its broad-leaved branches stretching over the water, and its large, pink, globular, composite flowers, three or four inches in diameter, suspended at the end of a fine down-covered stalk, nine inches or a foot in length. These hanging by hundreds along the course of the stream, surpassed anything of the kind I had seen, or could possibly have imagined. I frequently met with the *Astrapaea* afterwards, but always growing near the water, and its branches frequently stretching over a lake or river.’”

In further describing the scenery of Madagascar, Mr. Ellis states, in reference to forests, that they spread over the most unequal ground, covering mountain ridges, steep precipices,

River-bank Scenery in Madagascar.

along, we passed several patches of the beautiful *Nymphaea carulca* in blossom; and I do not remember ever experiencing more deeply the feelings of admiration and delight produced by new, and rich, and beautiful aspects of nature, than during my excursion on this charming water.

“After proceeding about a couple of hours, and passing the high land on our left, we entered a narrow creek between high banks of clay. Several birds here attracted my notice. But my attention was chiefly arrested by the flowers on the banks of the narrow stream, amongst them a plant which looked like a variety of herbaceous hibiscus, with bright yellow flowers, and a gigantic arum, *A. costatum*, or *A. colocasia*, which grew by the edge of the water to the height of ten or twelve feet, and so near that I could reach them on both sides as we passed along. But the most magnificent objects were the fine trees of *Astrapaea Wallachii*, or *viscosa*. The name of this Malagasy plant was derived from the word for lightning, on account of the brilliancy of its flowers; and Sir Joseph Paxton and Dr.

and broad or narrow valleys. ‘Many of the trees,’ he says, ‘are of stupendous magnitude, apparently of hard wood and slow growth, excepting some of the Dombeyas, which were magnificent trees. I noticed but few orchids, or parasitical plants of any kind; but creepers were abundant. Amongst them, some singularly curious bamboos. Of one kind the cane was almost as small as a quill, with a circle of fine small branches or leaves around every joint, the joints being not more than five or six inches apart. The long slender canes were often nine or ten feet long, hanging pendent from the branches of the trees, or stretching in graceful curves from tree to tree along the sides of the road.’”

Some beautiful *Lycopodiums*, it is stated, grow along the margins of the water, and even in some places may be found our own royal fern (*Osmunda regalis*). A species of *Platycerium*, or Stag’s-horn fern, also ornaments the stems of some of the loftiest trees, and ferns of other kinds are not at all uncommon in Madagascar.

THE INDOOR GARDEN.

CULTURE OF LUCULIA GRATISSIMA.

This is one of the most beautiful winter-flowering conservatory plants in cultivation, forming, when planted out in about equal portions of turfy loam and fibrous peat, large bushes eight or more feet in diameter, and filling the house with delicious fragrance in November and December. Some years ago, I had charge of a conservatory, in which several large plants of Luculia were growing beautifully in the borders; for, although it is rare to meet with a really good specimen in a pot, yet when planted out in good soil in a well-drained border, it grows as freely as a willow. The great thing is to prune well back after flowering; if this is not done, the plant rambles up, soon gets naked at the bottom, and does not flower so well. It often makes three or four feet of wood in one season, and the flowers are borne at the ends of the shoots, therefore it is important to facilitate the ripening of the wood as much as possible, by exposure to light and by reducing the supply of water in August and September.

The Luculia also makes a grand plant for covering the back wall of the conservatory, and there is scarcely any limit to the space it will cover. Liquid manure made from soot, and given clear during the flowering and growing period, adds to the strength and beauty of its flowers, and imparts a rich dark green tint to its foliage. The syringe or conservatory engine should be used frequently to keep the foliage clean. About the same treatment that suits camellias for blooming about Christmas will also suit the Luculia.

A really good specimen of this Luculia in a pot is not often met with, and the reason probably is, because the plant is usually encouraged to flower before a good foundation has been laid for the future specimen. And until it is well established in a good-sized pot, it seems rather impatient of being cut back; plants are, therefore, allowed to flower without being subjected to cutting, and it is somewhat difficult afterwards to induce a bushy habit. In commencing to form a specimen, begin with a young healthy plant, keep it growing in what is called an intermediate house, and persistently pinch or rub out the leading buds till a good foundation for the future specimen is formed. Do not allow it to flower till this object has been attained, and the plant will be longer lived in consequence. When potting is necessary, give a good liberal shift. What is termed among plant growers "the one-shift system" is well adapted for the Luculia, but then special care is required in watering and the drainage must be perfect. Although when making its growth the Luculia delights in liberal supplies of water, anything in the shape of stagnation at the root produces ill health, from which there is little or no recovery.

The best soil for pot culture is two-thirds turfy loam and one-third fibry peat, with a dash of fine charcoal. The soil should be well broken up, and rubbed through a coarse sieve without extracting the fibre. Pot firmly; loose potting encourages rapid growth, but this is often imminent to the formation of a good specimen.

It may be propagated by cuttings made of the young side-shoots taken off with a heel, and placed under a bell-glass in a cool place till callused, then plunged in a mild bottom heat. It may also be increased by means of layers. E. HOBDAY.

UTRICULARIA MONTANA.

AN arboreal or epiphytic Utricularia is a phenomenon as exceptional in the vegetable kingdom as are the flying-fish, tree-frog, land-crab, and similar anomalies in the wide domain of animated nature. Such a plant-wonder we have in the recently-introduced *Utricularia montana*—an acquisition to our collections, and worthy of extended cultivation, not alone for its botanical interest, but on account of the size and beauty of its delicate flowers. Any one seeing, for the first time, this plant in flower would be likely to smile sceptically if told it belonged to the same genus as the curious little Bladder-worts (*Utricularia*) of our pools and ditches. The fact is so, nevertheless, and our modest little aquatics have great reason to be proud of this exotic relative, which, ignoring the homes and habits of its kind, eschewing the pool and the marsh, finds its congenial feeding-ground

high up on the mossy trunks of trees in Trinidad, St. Vincent, and elsewhere. In habit, mode of growth, and the aspect of its flowers it simulates and rivals some of the prettiest of epiphytical Orchidaceæ—*Phalaenopsis*, for instance. In fact, when seen, for the first time, in flower and growing in orchid-fashion, even an accomplished plantsman might be taken in, and tempted to exclaim, "What a pretty orchid!"

It is scarcely more than a year since this lovely and interesting little rarity found its way to Europe. Scarcely was it introduced than, thanks to the never-tiring energy of Dr. Moore, a plant was secured for Glasnevin, where we had the pleasure of seeing and admiring it in flower on more than one occasion during the past month. The plant is a stemless epiphyte, with pale green, entire, narrow lanceolate leaves, from four to six inches long. The leaves spring from a fascicle of oval, hollow, green, semi-transparent tubers, formed on wiry fibrils, which bear at intervals minute bladders or utricles, similar to those borne by our home species, and whence the name of the genus. The flowers are borne on a slender curved wiry scape, and may number from one to five or more. They are very large, nearly two inches in diameter, the pedicels about three-fourths of an inch long, the calyx lobes pale yellowish green. The corolla is white, with a large yellow blotch on the centre of the lower lip, the upper lip or hood is roundish, with a truncated base. The lower lip is twice the size of the upper, very full and prominent in the centre, closing the throat and concealing the anthers; the spur is a stout curved horn-shaped body, nearly an inch long, of the same colour as the corolla.

As regards multiplication and growth, both seem to be of the easiest kind. The former is effected by means of stolons, which are freely produced somewhat after the fashion of the strawberry. At Glasnevin it accommodates itself and flowers freely, treated either as an epiphyte, and grown in a suspended basket, or as an ordinary pot plant in light, open soil. The first mode, however, seems to commend itself as being the most desirable way of growing it; for, as we understand, that in its native haunts the plant shows to most advantage when growing on trees, so in our plant-houses its effect will be enhanced when grown as an epiphyte or in a suspended basket. With regard to temperature, it requires, we believe, the heat of the stove, but as it is found not alone in Trinidad and other islands of the West Indies, but in New Grenada and Peru, it may very probably be grown successfully in an intermediate house where the heat is very moderate.—*Irish Farmers' Gazette*.

A REVISION OF THE GENUS DRACÆNA.

BY DR. REDEL.

(Continued from p. 637.)

DRACENA LATIFOLIA (RGL.)

LEAVES broadly-lanceolate or elliptical-lanceolate, from 2½ inches to 3 inches broad, and from 1½ foot to 1¾ foot long. In other respects like D. Rumphii. Flowers unknown. Southern Africa.

DRACENA DRACO.

Stem thick, tree-like, branching at the top. Leaves sessile, concealing the internodes of the stem with their half-clasping bases, crowded together at the extremities of the branches and stem, linear-lanceolate, attenuated into a sharp point, without a midrib, from 1 to 1½ inch broad, and from 1½ to 1¾ foot long. Panicle terminal, very much branched, with leaf-like bracts; ramifications ternate. Flowers four or five together, stalked. Corolla tubular, whitish-green on the outside, white within; divisions three times as long as the tube. Canary Islands, and cultivated in the East Indies and other tropical countries.

Varieties.—D. strictifolia, Hayne (D. canariensis, Hort.), has all the leaves erect-patent and closely-set. D. laxifolia, Hayne (D. Draco, Göpp. and Belg. Hort.), has the lower leaves recurved-patent and the rest erect-patent. D. pendulifolia, Hayne (D. Boerhavi, Ten., D. Ombet Kotschy and Peyritsch, pl. Timu.) has longer leaves, all recurved-drooping at the extremities.

DRACENA SALICIFOLIA.

A low much-branched under-shrub, with the habit of D. reflexa. Stem and branches flexuous, about ¼ inch in diameter, clothed with leaves from the base or from the middle up. Leaves recurved-patent, linear-lanceolate, not concealing the internodes of the stem with their half-clasping

bases, $\frac{2}{3}$ inch broad and from $3\frac{1}{2}$ to $5\frac{1}{2}$ feet long, undulated, and without a mid-rib. Flowers unknown. Java.

Synonyms—*Cordyline salicifolia* (Göpp); *Dracaena linifolia* (Hort.); *D. flexilis* (Hort.); *D. flexuosa* (Hort.); *D. reflexa* var. (C. Koch).

DRACENA SURCULOSA (LINDL.)

Rhizome emitting several slender, jointed, culm-like, half-shrubby stems, from 1 to 2 feet high. Leaves almost in whorls, oblong-lanceolate, or, less frequently, elliptical-lanceolate, narrowed at the base into a short channeled stalk 2 or 3 lines in length, acuminate at the point, with a mid-rib which is sunken in the upper surface of the leaf but prominent underneath, striated with veins, from $\frac{1}{4}$ inch to $1\frac{1}{2}$ inch long and from 3 to 4 inches broad; joints of the stem below the whorls of leaves covered with a clasping lanceolate acuminate scale which is leafless, scarious, marked with longitudinal veins, and very persistent. Raceme terminal, simple, corymbose. Flowers solitary, on thread-like stalks, $\frac{1}{2}$ inch long; bracts shorter than the pedicels; corolla of a yellowish-white colour, and sometimes an inch long; tube slender, cylindrical; divisions linear, as long as the tube. Tropical Africa.

A variety, *D. s. maculata* (Hook.), has the leaves marked with yellowish-white spots, and was found by Dr. Mann on the banks of the Old Calabar River.

DRACENA NIGRA (HORT. BEROL.)

Stem more or less flexuous, simple, short, covered with leaves at the top. Scales leafless, soon falling at the lower joints. Leaves oblong-lanceolate, $1\frac{1}{2}$ to 2 inches broad, and from 5 to $6\frac{1}{2}$ inches long, acuminate (sometimes oblong, elliptical, $2\frac{1}{2}$ inches broad and $5\frac{1}{2}$ inches long, and shortly acuminate), always undulated, attenuated at the base into a channeled stalk from $\frac{1}{2}$ to 1 inch long, with a slender midrib and more prominent longitudinal nerves and striated with veins.

Raceme terminal, nearly sessile, sometimes 3 inches long, thickly set with flowers, solitary or, more rarely, two racemes together. Flowers in pairs or three or four together, with a few scarious bracts, the lowest of which is longer than the pedicel. Corolla of a greenish-yellow colour; tube cylindrical; divisions linear, and of the same length as the tube. Native country unknown.

A variety, *D. n. maculata* (*Cordyline Sieboldi*, var. *maculata*, Fl. des Serres), has the leaves marked with yellowish spots.

Synonyms—*Dracæna Fontanesiana* (Rgl.), *D. elliptica* (C. Koch).

DRACENA SPICATA (ROXBURGH.)

Stem shrubby, erect. Leaves lanceolate, lengthened-acuminate, attenuated at the base into a channeled clasping stalk, which is sometimes 2 inches long, with a stout midrib, and striated with veins, $2\frac{1}{2}$ inches broad, and from 8 to 12 inches long. Scales leafless, solitary at the lower joints, herbaceous, lanceolate, acuminate, sometimes 3 inches long, often persistent for a long time. Raceme loose, stalked, terminal, about 2 inches long, exclusive of the stalk. Stalk ascending, 3 to 5 inches long, with a fascicle of herbaceous bracts at the base, and loosely set with other scattered acuminate bracts. Flowers solitary (sometimes three together), with scarious bracts which are shorter than the pedicels. Corolla becoming ultimately twisted; tube thread-like, cylindrical; divisions linear, shorter than the tube. I have seen specimens which were collected by Heyne in the East Indies.

Synonyms—*Cordyline spicata* (Fl. des Serres), *D. Wallichii* (Korth.).

(To be continued.)

GARDENIA FORTUNEI.

Of the many fine plants for which we are indebted to Mr. Fortune, we think that, tested by a jury of ladies, this would be pronounced the finest; for to the size, purity, and doubleness of the white camellia this plant adds the delicious aroma for which the whole tribe of Gardenias are so much prized. The great market growers who cultivate Gardenias by thousands for the supply of bouquet-makers at Covent Garden, grow them principally by means of the heat of fermenting materials. The general plan is to have a pit filled with spent hops from the brewers' or tan for bottom heat, and

then linings of stable manure around the sides of the pit. The plants in the growing season delight in a brisk, moist temperature—indeed, from the commencement until near the maturation of the growth, they will grow in a vapour bath strongly impregnated with ammonia; but to mature the wood and set the flower buds it is necessary that they be exposed to a drier atmosphere and a free circulation of air. Cuttings of the *Gardenia* strike with the utmost freedom in a close, moist temperature, with some bottom heat. Though heat from fermenting material is the most suitable for the cultivation of this tribe of plants, it must not be supposed that they will not grow in ordinary plant stoves. I have plants so treated now of G. *Fortunei*, G. *florida*, and G. *Florida intermedia*. During the growing season they are placed in the closest part of the stove, and are well supplied with manure water. When the growth is complete and the flower-buds forming, they are exposed to full air, and for months I keep them in a cool house with camellias. When we want bloom they will be removed to a forcing house, and there remain to make their growth. As a forcing plant, to come into bloom in March and afterwards, I know nothing so valuable as the *Gardenia*. It is a universal favourite with all who know it, and will ever remain so. The only drawback is that insect pests of every kind have a great affection for it. Mealy bug, white and brown scale, thrips, and red spider, each grow fat and multiply upon it. The best remedy for these pests is to lay the plants upon their sides, and then syringe them when in a dormant state with water heated to 120° ; then follow with a dressing of Abyssinian mixture of full strength, and the visitation will be subdued, if not eradicated. The kind mostly grown for flower-market purposes is G. *radicans*. It is a dwarf, free-blooming species, and, carefully managed, flowers most profusely.

PERMANENT SHADE FOR GLASS HOUSES.

The best permanent shade for plant houses is linseed oil and sugar of lead, in the proportion of about a teaspoonful of the lead to a quart of oil; but the exact tint must be governed by the amount of shade required. Therefore apply the lead gradually, and prove it upon a few pieces of waste glass until you get the tint desired. The *modus operandi* is this: first wash the glass thoroughly clean, and then (having previously prepared the oil and lead), on a dry clear morning, take the oil and paint as thinly as possible over the glass with an ordinary paint brush; then follow with what the painters call a dust brush, loosé and quite dry, and dabbing it gently on the oiled portion, impart a frosted or ground-glass appearance to it. An ordinary garden labourer, with a little practice, will do this very nicely. This shading will stand very well for a season, and if in the autumn it is desired to remove it, that may be readily done by washing with strong pearlash water. For some plants, such as camellias, oranges, and other strong-folaged things, it is questionable whether it is desirable to remove the shading. Many years ago, when there was much bother about the scorching by foreign, sheet, and other inferior kinds of glass, the late Mr. Pine, of the Exeter Nursery, who a short time previously had put up a large camellia house, wrote to a friend: "I made short work of the scorching; I painted the glass all over with white lead paint, and I found where the paint was the thickest the plants did the best." There has been a good deal of misdirection about the light necessary for plants. We bring them from all parts of the world, and, without giving a thought as to whether their native habitat may be under the shade of larger vegetation, or in open positions, we stick them in the full light, and then grumble because they do not grow as we could wish.

W. P. A.

Scottish Orchid Peat.—I wish to know if Orchid peat can be procured in Scotland as good as that used by the first English Orchid growers. If so, where? Also where the best silver-sand for garden use, is to be had in Scotland.—MELROSE.

Tobacco Smoke.—Tobacco smoke is a good servant but a bad master. There are some plants that never get used to it. Many Ferns (especially the young fronds), *Gloxiniæ*, *Caladiums*, &c., are among those that do not relish tobacco. Therefore, when Ferns get attacked by thrips it is safer to wash and dip, than to smoke them; and, if the latter must be resorted to, to expose the young fronds to the development of the thrips, and then dip the whole plant in water, and then smoke it. *Gloxinia* plants never seem to need smoking. Then skinfully down in a man's house, or pot-planted in a genial bottom heat, within two or three feet of the glass, and shaded during bright sunshine for a few hours on the early side of noon, they will continue clean. If thrip gets on them owing to their being grown in dry houses, their beauty will be greatly impaired. Aphides sometimes appear, and a gentle smoking will exterminate them without injuring the leaves. For it is a sine qua non that the penetrability, if I may so express it, of green fly, is very largely dependent on the presence of a strong, pungent, aromatic smell, such as an anch, or phim shoots, and it is almost indestructible by tobacco smoke. But let it eat cucumber or *Gloxinia* leaves, and a few puffs pierces its armour of defence, and it is dead. Hence it is not always needful to give all plants an equal dose of smoke, and it is even more certain that all plants will not endure the same strength with equal impunity.—D. T. FISH.

FLORA IN TOWN.

WHAT sweet shepherd is this with the fur cap, the grimy face, the torn jacket, who stands opposite our window, crowned with a hundred wild and garden flowers? Crowned, perhaps, is not the correct word, for the superb regalia is in a wicker casket; but then some of the leaves nod over his brow, and, if you did not recognise the costermonger, might suggest a Roman diner-out. There is nothing pastoral or arboricultural about this gentleman, however. "All a blowin', all a growin' ;" and on being asked from the area the price of a plant, he lodges his stock on the ground, and holding the flower-pot in one hand, he uses the other to give gesticulative force to its value and cheapness. It is a wonder how he contrives to keep alive the geraniums or more delicate azaleas in the awful lodgings to which he retires at night; and yet they survive apparently for several days, and may in the end have the honour of meeting death at a dinner party under the gaseliers, or in the bouquet that lies upon my lady's table.

Shall we find the traditional flower girl in the neighbourhood of a station? Scarcely. Where holiday-bound folk largely congregate, troops of worn, wretchedly-clad girls may be seen offering flowers for sale—but not as in the ballet. They are but unfortunate mendicants in disguise. Poverty and flowers you think ought not to be seen together. The hungry, pinched, wistful face appears more hungry and pinched when associated with the happy gathered children of the nurseries and the fields. And so from an instinct of compassion or sentiment, you give an alms to the flower-girl which you never thought of bestowing on her when she was otherwise engaged. She makes up pretty things for the button-hole of honest little Jones, who has escaped for a day from his office, and who has a necktie that would put the hottest poppy that ever flamed in an August corn-field out of countenance. Flora's alley in Covent Garden does not either present you with any nearer illustrations. The ladies in charge there remind you, perhaps, of the Rose of Sharon, and many of the names over the doors will contribute to the same idea. But you are oppressed with the riches of the place. It is Oriental in its aromatic spiciness and colouring. The sacrificial combinations to be employed at wedding obsequies are distracting to all but possible brides or bridesmaids. To what picturesque uses will these specimens of the art of the bouquettiste in yonder window be put? That bunch of gleaming flower jewels in the corner may be flung at the feet of Zelina, of Marguerite, of Maria, at the opera; or may be placed in front of a private box.

We alight upon our transcendental flower nymph at last. She is retained at the establishments to which those resort who would not think they were dressed without a yellow rose in the coat. She no more gathers flowers than she digs potatoes, and she contemplates them with as little sentimental regard as an apothecary entertains for a Spanish fly. She must, however, practise a certain amount of fascination in order to draw customers to the shop. She charges generally from a shilling up to three shillings for a button-hole flower, but two shillings is the average tariff. With care, a man may dine in the flower he has worn in the Row; but the ferns round the flowers are exceedingly fragile. Some of the bouquet shops have adopted the plan of sending a dozen or so of prepared little bouquets to the hall porters of the clubs. The hall porter disposes of them at a considerably reduced figure, but then it is supposed to be a different affair altogether to have the decoration attached to your lapel by a functionary in a scarlet waistcoat, and by a damsel who takes your florin after that service, with a smile as though she loved you.—*Daily News.*

The Shears in Old Irish Gardens.—The Huguenots of Dublin are credited with the first introduction of the shears, and it was used by them and their disciples with a vigour and a vengeance. Nature's loveliness and wildness was tamed, and an artificial wildness, a thousand times more wild, substituted. The Vandal shears began its sad havoc in the neighbourhood of Dublin, and there was scarcely a nobleman's or gentleman's seat through the kingdom that eventually escaped from its unrelenting usage. Box, palm, yew, evergreen, garden, and roadside hedge was not only docked, but these evergreen shrubs were cut into the shape of men, beasts, birds—wild and domestic. Streams were not let flow as they listed, but were taught to intersect each other, circumscribe islands, and expand into lakes. The Dutch mind of King William's followers had little discrimination or taste as to the effect or nature of landscape—they were not fond of the sunk foss'd or fence. Like their countrymen, who beat back the sea, and built up their cities on piles, the Dutch in Ireland beat back the face of nature from their plantations, built up high walls around their gardens and improvements, and unkindly shut out a view of their grounds from the people, and in doing so shut out the view of the surrounding country. Long avenues all in shade, and shady groves all in gloom, were the approaches to their mansions, and heathen deities or myths did services in the form of flower-pots or pedestals on their parterres.—*Dubliniensis, in "Irish Builder."*

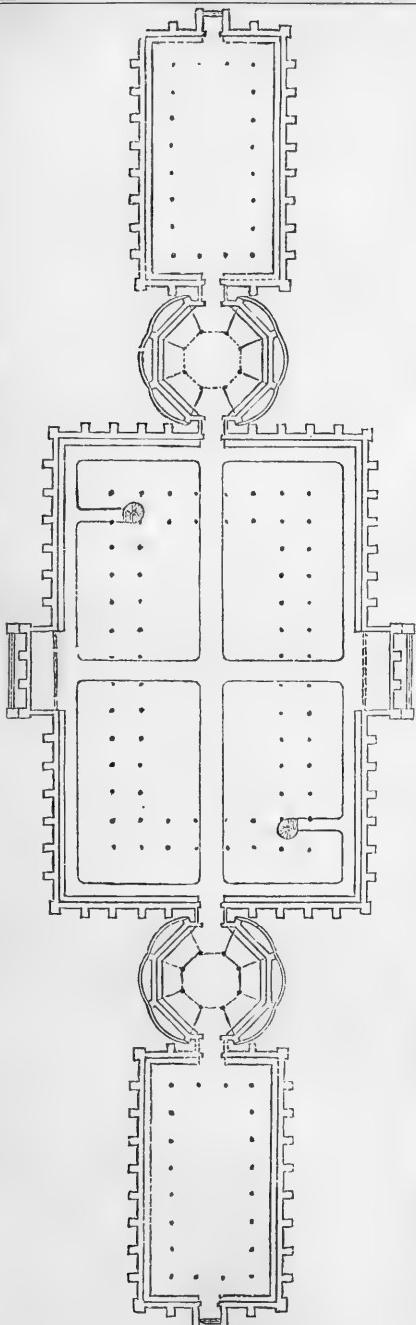

PUBLIC GARDENS.

THE ROYAL GARDENS, KEW.

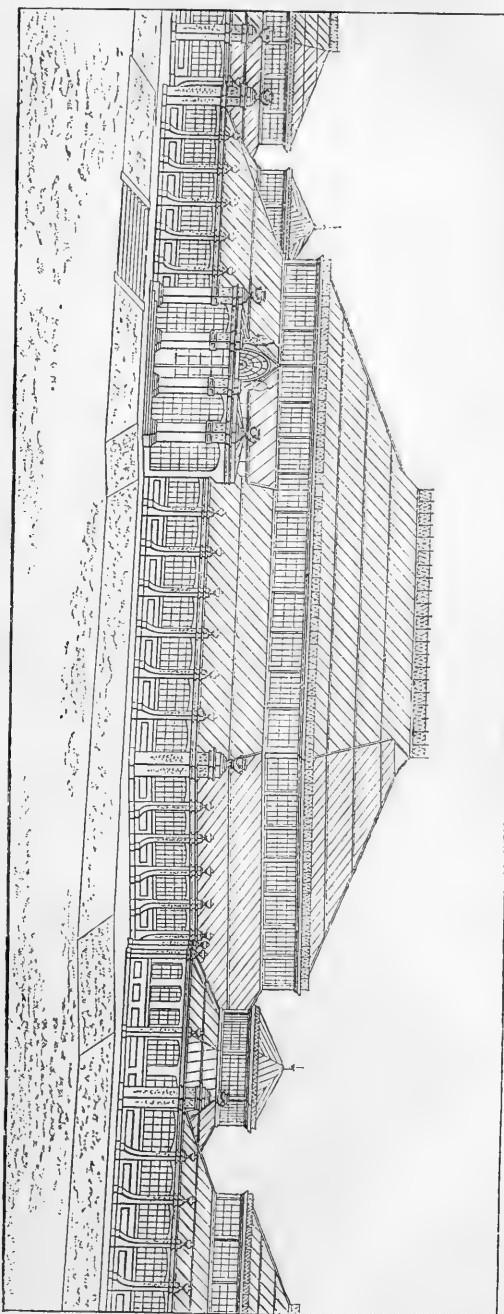

THE GREAT TEMPERATE HOUSE.

This is undoubtedly one of the finest and most satisfactory features of Kew, and one of the noblest garden structures yet erected. The almost unequalled collection of temperate-country plants which it contains, many of them of an ornamental character, and most of them in prime health, planted out in borders, makes it particularly interesting and instructive to all classes of gardeners. In fact, were it not for the awkward arrangement in the central parts of the house, one might point to it as a model of the largest class of winter gardens; but the huge mass of iron pipes piled up along the central wall completely spoils that air of repose which a noble conservatory ought to possess. Indeed, the great number of exposed pipes looks more like what one might expect to see in a factory-yard than in a garden. Of course, there was not the least occasion for thus obtrusively placing these pipes, which might easily have been concealed. In 1859 the Government granted the sum of £10,000 towards building this conservatory. Mr. Decimus Burton was directed to prepare the designs and Messrs. Cubitt & Co. were appointed to carry them out. The site is on the west side of the great avenue leading to the Pagoda. The building, as the accompanying plan and view explain, stands on a terrace about four feet high, approached by wide flights of steps at the sides and ends; and consists of a centre and two smaller conservatories, octagonal in shape. The wings beyond these octagons, though we have thought well to show them as part of the plan, have not yet been built. The internal dimensions of this house are respectively as follows:—The centre portion, 212 feet 6 inches by 137 feet 6 inches. Each wing will be 112 feet 6 inches by 62 feet 6 inches. The intermediate octagons, 50 feet in diameter. The total length of the building will be 582 feet, and its superficies, 48,392 feet—about 1½ acres. The Palm House at Chatsworth contains about 15,276, that at Kew, 24,200, and the conservatory at Sion, 7,785 superficial feet. The building presents an ornamental continuous façade, having wide glazed openings and stuccoed piers, on a stone plinth two feet high. The centre roof is 60 feet high, and is constructed of wrought-iron framed arch principals, springing at 36 feet 6 inches above the floor from cast-iron standards three feet wide, which are bolted down to granite blocks, bedded in brickwork and concrete. The standards are connected together, at the springing of the principals, by two sets of cast-iron longitudinal arched girders. A gallery-floor of rolled plate-iron forms a continuous bond at this level. A portion of each standard is continued 8 feet above the gallery-floor, to support the curb and rafters of the upper roof. These rafters are of wrought-iron, 52 feet in length, with feathering rolls on each side to receive the sliding lights. There are three tiers of iron purlins, secured to the principals and rafters, and wrought-iron diagonal wind-bracing riveted to the under side of the latter, and vertical bracing on the upper portion of the principals. The upper ridge is of rolled iron, and receives the end of the rafters and an ornamental ridging of cast-iron. A bold cast-iron cornice gutter conveys the water of the upper roofs to a hollow portion of the vertical standards, whence it is conducted through underground iron pipes or tanks under the terrace.

The proposed wings will be 37 feet 9 inches high in the centre, the roofs formed by wrought-iron arched ribs springing from cast-iron columns, which serve as rain-water pipes, as in the centre house; cast-iron spandrels support the rafters on which the lights traverse. Straight instead of curvilinear rafters are necessarily adopted, to allow of the roof being uncovered during several months of the year. An apparatus for moving the sliding roof-sashes has been devised, by means of which the three upper of the four tiers of lights covering the sides of the roof of the centre house are passed one over the other, and rest on the lowest tier. The power employed is that of the wheel and endless screw, worked at the level of the gallery, and is such as will enable one man to cover or uncover each bay of five hundred feet superficial area in about five minutes. The vertical sashes throughout are hung on centres. Those on the ground floor and gallery are opened and shut by hand,

VIEW AND PLAN OF THE GREAT TEMPERATE HOUSE IN THE ROYAL GARDENS, KEW.

and the remainder, together with the lights of the lower roofs, by machinery. About 63,848 superficial feet of glass have been used. There are vaulted basement stories to receive the heating apparatus under the octagons, in which the trees and plants which require most warmth are placed. The temperature of the other compartments is only about 40° in winter. The heating is effected by hot water circulating in four cast-iron pipes placed under the filleted tables around the sides of the house throughout. The centre contains four thousand yards' run of pipe, the wings will have two thousand yards, and the octagons have seven hundred, or collectively about seven thousand yards (3½ miles). There are gravel paths and beds for ploughing trees and plants throughout, except in the octagon buildings. The water tanks contain upwards of 150,000 gallons collectively, from which the water is drawn by means of pumps placed in convenient situations in the building.

THE FRUIT GARDEN.

THE BEST HARDY FRUITS.

VERY recently Mr. D. T. Fish suggested, in the pages of the *Florist and Pomologist*, the desirability of gardeners in different parts of the country giving their opinion of the fruits most desirable to be cultivated in our gardens. This invitation has been responded to by sixteen of the most experienced gardeners in Britain, and the result has been tabulated, giving the names of all the fruits enumerated, and the number of votes for each variety. Of course, each reporter speaks from his own source of observation, and hence, though the winning fruits are indisputably excellent, it is not too much to say that many of the unsuccessful varieties are not less deserving of cultivation, though not so generally esteemed.

The most remarkable result of the selection is that, notwithstanding the wide amplification of our trade catalogues, the parade which has been made of "magnificent new varieties," and the certificates awarded to them, in no single instance does a new fruit of the last quarter of a century advance to the front position; if it does, it is the Victoria Plum, which gains thirteen votes, against twelve for Greengage, eight for Cee's Golden Drop, seven for Early Rivers, the same for Jefferson, and five for Kirke's, which are the six selected. Still, twenty-four other varieties are named, among which are several of great excellence, as Reine Claude de Bayav, Autumn Compôte, Washington, Pond's Seedling, Prince of Wales, &c., while some, looking to seasonable supply no doubt, recommend Damson, Prune Damson, and even White Bullace.

Beginning, however, at the beginning of the list, for the best two Peaches, Royal George leads with ten supporters, and Barrington follows with five; Bellegarde, Grosse Mignonne, and Noblesse occupying third place, each with three supporters. Of new kinds, Early Alfred is the only variety named, and that with one supporter only. Téton de Venus and Walburton Admirable rank in the same category, though in their season both are first-rate.

In Nectarines, Elruge occupies the place of honour, with ten votes; Downton and Violette Hative having four each for second place; Victoria (Rivers) ranks with Pitmaston Orange for the third position; while Pine-Apple (Rivers) and Rivers' Orange have each only a single supporter. Mr. Baines, I see, supports Balgowan, and I share his appreciation. As I knew it twenty years ago or more upon the peach wall at Chiswick, it was one of the finest and best nectarines I ever saw, though I have shown some of them weighing eight ounces each.

For the best two Apricots, I might almost say there is only one candidate, and that is Moorpark, with fourteen votes; Kaisha and Orange following with four each, though the latter, except for preserving, is not worth wall room.

For the best three Cherries, May Duke is first, with thirteen votes; Elton follows with six votes; and Black Tartarian holds third place, with five votes. Of course, these are all summer cherries, and though good in their way, are not, for general usefulness, to be compared with Morello and Kentish, as these, properly managed, are all-the-year-round cherries.

In Red Currants, Raby Castle holds the first place, with twelve votes; Red Dutch is second, with nine supporters; while

all the rest may be said to be nowhere. In blacks, Black Naples has fourteen supporters.

For the best four Gooseberries, Red Warrington has fourteen votes, Whitesmith nine, and Red and Yellow Champagne four votes each. Twenty-one additional kinds are named, among which, as a dessert fruit, Greengage is an excellent variety, not so well known as its suggestive name and superior flavour demand. Of the best four gooseberries for size, London is first, with seven votes; Antagonist and Thumper have equal second places; Crown Bob, Roaring Lion, and Stockwell stand third; while Green Overall and Wonderful are equal for fourth place, fifteen others being named.

In Pears, Louise Bonne of Jersey is first, with twelve votes; Marie Louise second, with eleven votes; Williams's Bon Chrétien has the third place; while Beurré Diel and Winter Nelis share fourth honours; Beurré d'Amanlis, Josephine de Malines, and Jargonelle the fifth place; and Bergamotte Esperen and Jersey Gratioli the sixth place. Twenty-seven other varieties are named, among which Doyenné du Comice and Beurré Rance are not the least meritorious. What surprises one, looking to supply, is that the last-named should only have one supporter, seeing that as a spring pear it has no rival. Thompson's and Knight's Monarch are in a similar predicament, and so are many other fine kinds. For many years in the early part of my life, Beurré Diel was found worthless; indeed, the first time I ever tasted it really good was in North Wales, on the sea-board, and I have since found it excellent in this county.

In Apples, Dumelow's Seedling, or what in the Midlands we call Normanton Wonder; and in other places, Wellington, holds the first place, with eleven votes; Blenheim Orange, the second place, with ten votes; Cox's Orange Pippin has the third place, with nine votes; Lord Suffield is fourth, with nine votes; King of the Pippins is fifth, and Cox's Pomona sixth. In addition to these, thirty-seven other kinds are named, all more or less good, and some super-excellent. What surprises us Notts folks is, that two of our favourite kinds, the Eve, or Pomme de Paradise, and Bess Pool, are altogether ignored. The Eve, as an autumn dessert apple, is scarcely inferior in flavour to the American Newton Pippin as imported, while in fruitfulness and beauty it has no superior. In our markets it will always command twenty-five per cent. more than any other kind, and when scarce, fifty per cent. The same may be said of Bess Pool for quality, but it is an uncertain bearer, and given to crack.

In Strawberries, Keens' Seedling stands pre-eminent. Dr. Hogg is second, while Sir J. Paxton, President, and Sir Charles Napier are equal for the third place. Thirteen other varieties are named but only four of them got a single vote each; that best of all strawberries, where it can be grown, the British Queen, being in that predicament.

In Raspberries, Fastolff is first, with ten votes; Red Antwerp second, with five votes; and Prince of Wales third; while for the remaining varieties scarcely a dual vote is recorded.

So far, then, as this appeal to the country is concerned, the result is decidedly conservative; our old institutions are in the main supported, and though many radical changes have been forced upon us, this test vote is not in their favour. More than ever, then, I say to fruit-growers, Look to selections, not collections, for though among the "novelties and new things" there are, undoubtedly, some sterling acquisitions, their number is few, and the difficulty of selection great.

Newark-on-Trent.

W. P. ATRES.

Mexican Bread Fruit or Chayota Plant.—Dr. C. Naphegys lately read a paper, at New York, descriptive of a plant which he said had been introduced from Mexico. It was there called the Rima or Chayota plant, and bore a fruit covered with a thorny skin, containing a juicy pulp and one seed. Besides this fruit, it produced a crop of tubers similar to potatoes on the roots, and so far as he knew, was the only plant that thus produced a double crop. He believed it would be a valuable acquisition to that country. The fruit was pleasant and nutritious when cooked, and the roots were much like potatoes when boiled, and furnished a farina or flour similar to arrowroot. It was productive bearing eighty fruits and three to five bushels of tubers on a single plant. It could be grown in New York by being started in a hotbed in the fall and protected until May, when it might be planted in the open ground. It required eighteen feet of ground for each plant.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Orchards of Seedling Trees.—As regards palms will reproduce themselves from seed without much variation, such for example, as the German Prune. I believe it is propagated throughout Germany in this way. The Greengage I have also had from seed without much variation. Apricots, too, come pretty true from seed.—J. P.

Monsters deliciousa.—As regards this noble-looking plant, and shall be glad of few hints to that end.—J. S.—[Nothing can be easier in any stove or structure in which a pretty high temperature is kept. It is best planted out in rich soil, and afterwards merely requires plenty of water and heat. It grows freely in any soil, but particularly when we desire to perfect the fruit thoroughly in this dull climate, it is certainly much better to give it the full sun, and not keep it too far from the glass.]

Orange trees in Vines.—I should like to see the good (if old) fashion of planting out orange trees against the back walls in vineeries once more revived. There is no more ornamental covering for the wall; the trees thrive and fruit well in the shade of the vine, and with very little trouble to the gardener. The flowers as well as the fruit would prove very acceptable, and many a back wall now bare would be rendered both beautiful and useful by covering it with orange trees.—H. V.

Best Dessert Pears.—Kindly give me a selection of the best dessert pears, as I am planning a fruit garden.—Enya.—Jargonelle, Louise Bonne of Jersey, Urbaniste, Flemish Beauty, Mario Louise, Williams's Bon Chrétien, Beurré d'Anjou, B. de Rance, B. Diel, B. Superfin, B. Hardys, B. Sterckmans, B. Easter, Knight's Monarch, Bloodgood, Baronne de Mello, Bergamotte Esperen, Winter Nelis, Josephine du Malmaison, Thompson's Pear, Duchesse d'Angoulême, Glou Moreau, and Fondante d'Automne.]

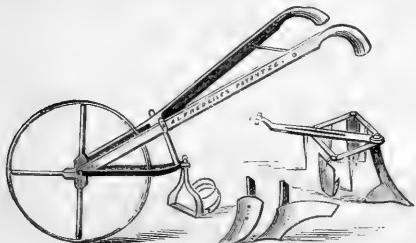

Cause of Bunches Dropping off Vines.—I beg to inclose for your inspection two bunches of vines, and will be grateful if you will tell me what is the cause before they come into complete bloom, as every one despatched will fall off. These are in pots, well established; they are in a temperature varying by day from 65° to 70°, and by night from 55° to 60°. The house is kept moderately moist; all the bunches go in the same way; some on which the berries are only just formed are gone.—J. A.—[This frequently happens also with pot vines which have been forced on an advance of the roots, or whose roots are in some loose, rich material, such as rotten manure or leaf mould.]

TOOLS, IMPLEMENTS, &c.

GILE'S PATENT HAND GARDEN PLOUGH AND GENERAL CULTIVATOR.

This is a very handy and effective little implement, especially adapted for manual operations for the cultivation of the soil on a small scale, as in gardens, nursery grounds, and market gardens, cottage gardens, or allotments, &c. It is the patented invention of Mr. Alfred Giles, Rugeley, Staffordshire.

This novel cultivating appliance has not long been introduced, and has gained repute as a labour-saving machine, being well

Hand Garden Plough and General Cultivator.

adapted for hoeing and scarifying between root-crops, drills, or ridges, in garden or field, and entirely superseding ordinary hand-hoeing. As will be seen from our engraving, it consists of a single light wheel, carrying a light and strong wrought-iron frame to which a variety of implements can be affixed, which conjointly make it a most economical, complete, and useful machine. A light but strong steel shovel is adapted for marking out rows for planting, or for loosening up the soil after the young plants are up. There is also a small steel plough, which can be used for the purpose of ridging up the rows when desired; and a weed-cutter, with rake attached, for hoeing out and exterminating weeds and generally pulverizing the ground and obtaining a good clear tilth. All these pieces are made separate, and can be easily and readily affixed or detached, by the aid of a small iron wedge. When in operation this implement can be pushed by hand through the ground, stirring the surface soil, to the depth of six inches, whether light or heavy. It is exceedingly light, strong, and neat in construction and appearance, and adapted to the purposes designed.—*Mechanics' Magazine*.

A PRUNING CHISEL.

The use of a heavy chisel in pruning has often been advocated in these columns. We give below a description of one used by Mr. J. S. Needham, West Peabody, Massachusetts. The drawing is one-fourth the real size, which is, including socket, 9½ inches long, and from the point to the shoulder, 1½ inches. Width across the point, 2½ inches; narrowest part, near the socket, 2¼ inches. The cutting edge, which is alike on both sides, is bevelled back to a distance of five-eighths of an inch from the edge. The chisel is three-eighths of an inch thick near the shoulder, and tapers gradually to a strong point. A somewhat similar tool is made in Pennsylvania, and the manufacturers would do well to place it more prominently before the public. In a note accompanying his drawing, Mr. Needham says:—

"I find that by standing upon the ground I can see much better what limbs ought to be removed to preserve the balance of the tree, as well as those that are soon to interfere and chafe each other. I could make but slow progress with a long-handled saw; and by using a common chisel a portion of the bark on the stub would be

New Pruning Chisel.

started up. This chisel, having a concave edge, cuts drawing; the outer edges entering first, operate as a wedge, leaving the dead cut at the centre, with very little friction. By having a handle four or five feet long, most of the branches of any orchard of less than twenty years of age can be reached. By placing the chisel drawing-wise, branches 1½ inch and less in diameter can be cut off by four or five blows with a common mallet. The stub is left smooth, slightly convexed in its centre, with the bark unbroken. The work has a finished look, and is done in less than one-fourth the time in which it could be done with a saw. The cost of this chisel, made to order (by a pattern), was one dollar."—*American Agriculturist*.

The Best Kind of Garden Trowel.—I have tried to get the trowel you figured and praised so highly at p. 431, but have not succeeded. Will you kindly tell me where it is to be got?—S. S. [It is manufactured by Messrs. Wm. H. & Sons, Brades Street, and Edge Town Works, Oldbury, near Birmingham. That letter is stamped upon the trowel (W. H.) and their initials, and the crown signifies that the trowel is of best quality—all solid cast steel. These trowels may be obtained of any respectable ironmonger in the United Kingdom.]

THE PROPAGATOR.

LITHOSPERMUM FRUTICOSUM.

This singularly beautiful little plant is a real gem on outside rockeries in spring and early summer, the intense blue of its flowers being quite equal to that of any of our alpine gentians. It is a compact-growing, old-fashioned, little plant, and the freedom with which it may be increased, places it within the reach of everybody. It may be propagated either by means of division, or by cuttings inserted in a warm border under a hand-light in summer, and shaded for a few days with a piece of mat or other material. The following is, however, the best and most certain mode of increasing it:—A few of the plants should be lifted and potted early in autumn, so that they may have time to get well established before the winter, and have the protection of a cold frame after the middle of November. The sashes should, however, always either be drawn completely off, or tilted up on the side opposite to the direction from which the wind blows, unless the weather is too severe to permit of such being done. Towards the end of February these plants should be looked over, cleaned, top-dressed, and introduced into the propagating pit. This sudden change induces them to make young growths rapidly, which may be taken off and inserted as ordinary cuttings. They strike root readily, when they should be potted singly into thumb pots, and again plunged in bottom heat, where they soon establish themselves, and, after they make another two inches of growth, their sashes should be cut off for a similar purpose. A week or so after being deprived of their tops they should be lifted out of the ploughing material, and, after being levelled, set for a day or two on the top of it; then they should be placed on a side shelf near the light.

Unless it is necessary to obtain a large stock of this plant, it is not advisable to take more than one cutting off each cutting; but the old plants, from three weeks after they are brought in until a sufficient quantity of young plants has been obtained, will, if properly treated, continue to yield cuttings abundantly. No flowers should be permitted to develop themselves during the season of propagation, as their

presence only hinders that work, as well as exhausts the plants. Thus treated, compact little plants may be had in about two months, and before planting them out they should be gradually but thoroughly hardened off; indeed, I do not think they can ever be safely trusted outside before May. Six or eight good plants started in this manner in February should, by the end of April, furnish at least three hundred good young plants.

W. F.

Primula japonica.—This seeds freely; a fact which many will be pleased to hear. The seeds should be sown in light soil, mixed freely with silver sand, in pans, placed in cold frames, where they should be allowed to remain until they germinate. Two years may probably elapse after sowing before the young plants appear. Several pans of this seed sown in September 1870, and treated as I have described, are only now showing signs of vegetation. The young plants are now, however, coming up nicely. The first of them appeared about the beginning of last month, and were pricked into other pans, which are kept in a little heat; since then they have made considerable progress. The seed pans from which the first lot was obtained have since then produced another supply, and others may also continue to come up in succession, until all have germinated. Hitherto many good seeds have, doubtless, been thrown away ere they came up, a circumstance that happens too frequently with other things besides this primrose. Another cause of failure is placing the seed pans in heat; they should be kept cool. After the young plants are pricked off and potted, they are sometimes benefited by a little heat, just to start them afresh; but they must afterwards be carefully hardened off.—W. F.

Stripping Cuttings of Bedding Plants.—Allow me to contribute a small item to Mr. Gardner's "Gardener" (see p. 451) on the subject of bedding plants, which I think will render it still more simple. If the small plants which he mentions are filled with sand, and sufficient soil is then poured on from a rose to just cover it, the most delicate cutting (that is not flagging), may be easily stuck in without the aid of a dibble, which is certainly a saving of time. I may also add that in propagating such things as Verbena, Ageratum, Iresines, &c., in spring, it is not at all necessary to cut to a joint, or to remove the leaves at the joints; the cuttings may be inserted just as they are taken off, provided the first joint is placed below or on a level with the surface.—A. BARDEMAN, Whitfield, Dorset.

Raising Ferns from Spores.—Can you or any of your correspondents give me a few hints about raising ferns from the spores or seeds? How am I to know when the seed is ripe for planting, and what is the best mode of effecting it? Can it be done out of doors, or must the ripe fronds be picked off and put into a pot for the winter?—P. W.—You will know when the seed is ripe by the rich brown colour of the spore cases on the back of the fronds, the lower ones being the first to ripen. When dry and placed in a paper bag, the seeds will preserve their vitality for a very long time. You can now raise as soon as they are ripe, in the open air if you choose, but your chance of success will be greater if you sprinkle the seeds on the surface of moist soil in a seed pan, in a cool pit devoted to ferns, &c., not covering them with soil, but placing a sheet of glass over the pan, and keeping it there until the seeds have germinated. The seed pan should be kept moist by standing it in a water pan.

Paramelle's Researches in Reference to Subterranean Water.—Allow me to direct attention to a modern, and yet imperfectly known, science, the application of which has considerable practical importance. I refer to the science of studying subterranean waters, the kinds of ground where they are to be found, their flowing, the physical laws that govern their abundance or scarcity, and their depth. The circumstances accompanying the circulation of water on the surface of the earth have been thoroughly studied, but few persons have surmised what becomes of the rain-water absorbed by the earth, and still fewer have tried to account for its disappearance. A Frenchman, however, named Paramelle, resting his researches on sound geological knowledge, devoted himself to the solution of this problem, and to the application of principles which he had discovered by long experience. The science is now complete, and has received the name of "hydroscopie," or subterranean hydrology. Its applications are perfectly definite, and among them we must place in the first rank the discovery of springs and selection of well-sites. The immense practical benefits it is possible to reap from such a science should be well considered, for many towns, villages, and private estates, at the present time are deprived of water, or obliged to get it from remote places at an enormous expense; but so grave a deprivation is no more irremediable. Within easy access of every village, almost of every house, and generally at a little depth below the surface of the soil, there exist subterranean streams of water. By a simple digging (indicated after a thorough survey of the place, and by the aid of those clever divining rods that have made so many dikes) one can channel out these hidden streams, and make them flow on the surface; or else, a well can be sunk on their course, and the place formerly deprived of water will become abundantly supplied with it. No science deserves more to be studied, yet it may be proposed that these are promises of theory, and that practice may considerably lessen such expectations. To this I will reply, that the applications are not to be made, that Paramelle has discovered in France over 9,500 springs, and that he has disciples, who are not less successful than he was, who continue to illustrate by facts the excellence of the method.—LEON JOURD'HUI, Twickenham.

THE ARBORETUM.

PICEA AMABILIS.

The Californian silver fir tree, of which the annexed is an illustration, is that known to arboriculturists as *Picea amabilis*. It is taken from a photograph of a view in California, in the Yosemite Valley, in which a fine specimen occupies the central position in the landscape.

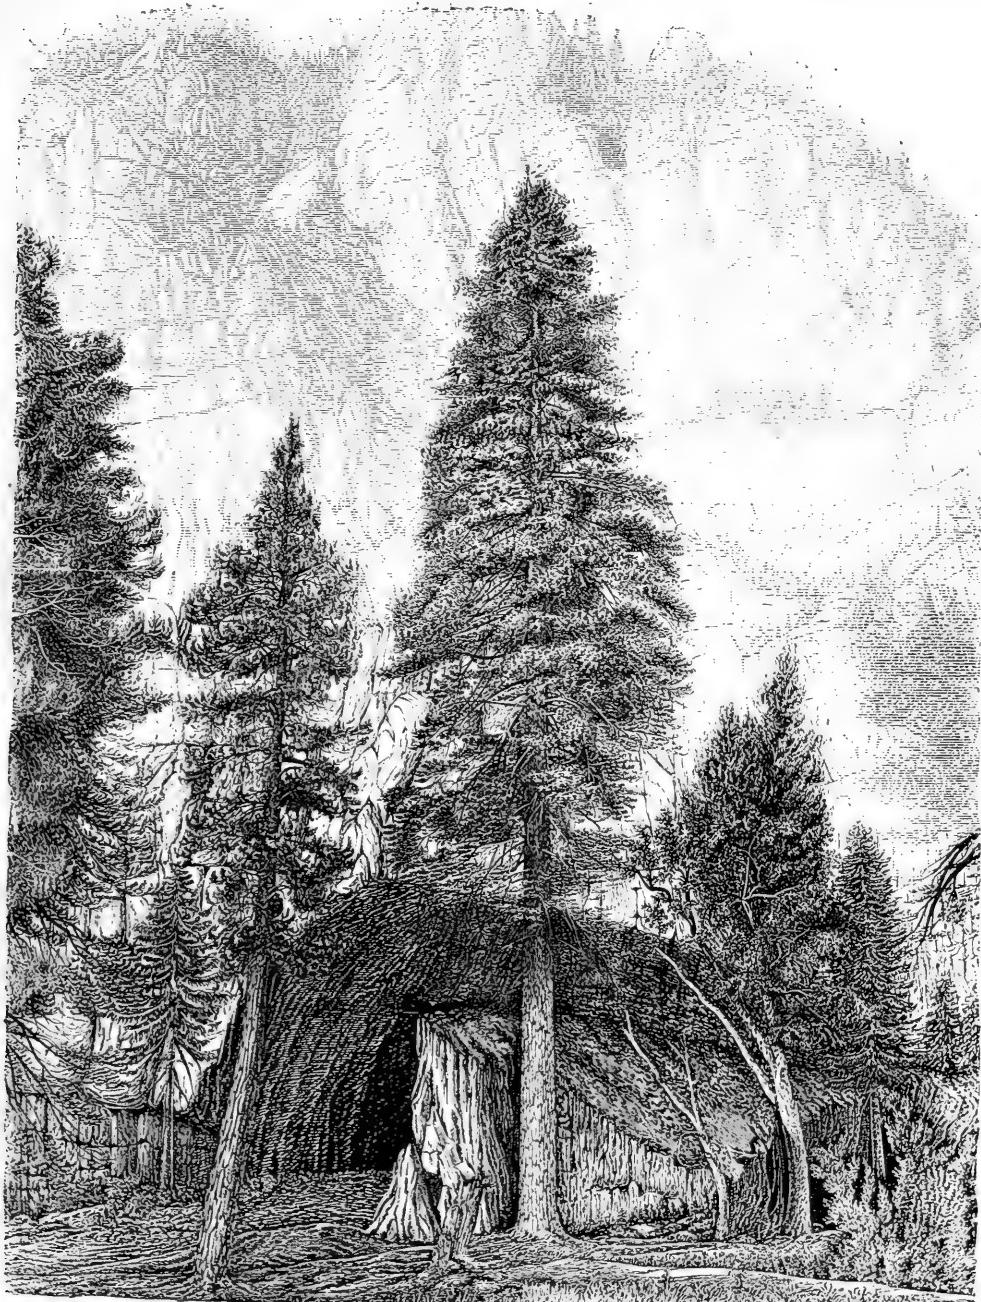

We have had to use the qualified expression of "known to arboriculturists as *Picea amabilis*," because, although generally known by that name, it is not the name by which it would be known if the laws of priority were respected. But this is just one of those cases which show how powerless all laws are against any practice to which common consent has given permission and currency; and there is justice in the disregard of law here, because it adopts the course desired by the original discoverer of the tree (David Douglas). It is surprising that there should be any confusion in the synonymy of this species, for of all the Californian flat-leaved silver firs, *P. amabilis* is the most easily recognised; and is, indeed, at once distinguishable by its foliage alone. There are three types of foliage among silver firs in California. There is the curly-leaved type, as *P. nobilis* and *magnifica*; then the flat-leaved type, in which the leaves are disposed on each side of the branchlet, with few or none along its upper side, as *P. grandis* and *Lowiana*; and, lastly, the flat-leaved type, with the leaves liberally and flatly applied to the upper surface of the branchlet as well as to its sides. This is our tree—*P. amabilis*.

It is between it and *grandis* that the confusion has arisen. *Lowiana* and *lasiocarpa* (if there be a *lasiocarpa* different from *Lowiana*) were then unknown, but Douglas sent home to the Horticultural Society specimens and seeds of two kinds, which he proposed to call respectively *grandis* and *amabilis*.

Lambert first described one of these (our tree), but he inverted Douglas's names, and described his *amabilis* under the name of *grandis*, and, most unfortunately, he either figured the foliage from a stripped branchlet, from which many of the leaves had fallen, so that it looked more like *grandis* than *amabilis*, or he mixed up the specimens, and took the cone of the one and the foliage of the other. But the description and the other details leave no doubt that *amabilis* was the tree which he meant to describe. A year later (1852) Dr. Lindley was engaged in writing the botanical part of "The Penny Cyclopaedia," and when he came to *Abies grandis*, he, having to give a description of it, referred to Douglas's specimens, which were then in his hands, and although he apparently did not know that Lambert had inverted the names, he probably observed that his description of Douglas's *grandis* was not a correct description (which of course, not being meant for it, it could hardly be); and so, taking the original specimens ticketed by Douglas himself as his guide for *grandis*, he described it from them under that name. That description, of course, does not apply to our present tree.

Next came Loudon, who took one half of his figures from Lambert's figures (which were *amabilis*), and the other half from Douglas's specimens of *grandis*, and his description entirely from Lambert. The evidence of all these circumstances will be found given at length in one of Mr. Andrew Murray's papers on the synonymy of conifers, published in the *Proceedings of the Royal Horticultural Society* in 1863. Strictly speaking, therefore, the rule of priority would reverse our present names; but amid so much misconception and blundering we apprehend that, on the whole, the common sense of arboriculturists has done wisely in sticking to the names originally proposed by Douglas himself.

The name *amabilis*, given by him to this tree, is well chosen. It is truly a lovely fir; it is the American type of *Nordmanniana*, darker and greener in the hue of its foliage, but not more lovely. Of course, we have no large trees of it in this country, and can only form an idea of what it will grow to by means of drawings or photographs taken from specimens in its native country. But we have already observed one thing with regard to these, as compared with the result in this country, wherever Californian trees have already attained some size with us, and that is that they are turning out much handsomer trees

PICEA AMABILIS IN THE YOSEMITE VALLEY.

here than the Californian photographs would lead us to expect. All the coniferous trees, especially the fir trees in North-West America, as they appear in the photographs sent home, have very much the same port; drawn-up, narrow, and confined, like a grenadier at attention. Such is the Douglas fir in California and British Columbia. But not such is its port here. There it has grown hedged in by a close growth of other trees of the same kind, and so has been drawn up. Here, where it has not been so dealt with, where it has been "trained abroad its arms to wield," it sends out immense branches on every side, like great trees thrusting themselves obliquely to heaven, from the trunk. So, no doubt, will it be with others, and so may it be with amabilis; we admire its beauty in the plate on the opposite side, but that may not be the beauty which we shall find on our lawns. We may fairly look for "another beauty and an added grace," when dealt with by our gardeners here.

GREAT MORTALITY AMONG EVERGREENS IN AMERICA.

THE winter's frost has caused wide-spread disaster. From Virginia to the Canadian shores, and from the eastern slope of the Rocky Mountains to the Atlantic, evergreens are everywhere dead or dying. Millions of dollars' worth of hardy plants, says an American paper, that have for years withstood the northern winters, now show the ravages of the zero weather of the last season. Norway spruce, pines, arborvitae, junipers, rhododendrons, dwarf and standard roses in public parks and private gardens have "put on the sere and yellow leaf," their symbols of decay. Long Island has suffered severely. In the gardens at Astoria, where immense numbers of evergreens were growing for sale, the loss is estimated at hundreds of thousands of dollars. Rows of arborvitae, containing thousands of plants, are absolutely valueless. Prospect Park and the private gardens in Brooklyn have not been spared in the general disaster, and the gardeners at the Central Park, New York, pronounce the loss in those grounds almost irreparable. At Flatbush, and in Westchester county, the loss has been very great. Some of the nurseries have lost their entire stock. In other places the effect has been peculiar. Plants of the same age and apparent health, growing in long rows, have been touched at intervals of a few feet. The first dozen in the row are dead, and the next half dozen are well and thrifty. In Brooklyn, the plants on the north and east side of the houses have suffered most. In New Jersey it has been noticed that plants which were shaded from the winter sun have escaped the worst effects of the season, and may be saved with much trouble and time. The reports from the vicinity of Boston and further east confirm the sad tidings of what was only rumour a few weeks ago, and from the great nurseries at Rochester, the Ohio Valley, and even further west the words come to us, "Our evergreens are dead." The causes assigned for this unexpected loss are various, but from among them the following may be taken as having in them most of probability: First, it is said that the warm days of February gave the plants an early start, as if the spring had really opened, and then when all were swelling with new life the weather changed again to hard winter freezing, with cold March winds. Another view is that the plants were killed very early in the winter. There was not a gradual diminution of the temperature as in former years, but the season came suddenly upon them before they were properly shielded or prepared for it. Their colour changed slightly, but not enough to cause alarm, and although the plants remained green they were dead. Only when the warm weather of the last few weeks started the other plants into general activity was the damage to the evergreens visible.

Mr. Sargent says, in reference to the effects of the severe frosts of March on the trees and shrubs at his place on the Hudson, that "it would be difficult to give with certainty the cause for the severe damage inflicted upon almost every sort of vegetation without first recapitulating the beginning of the evil two years ago, in a very severe drought, so severe as to denude many trees of their foliage in August and September; a mild and wet and somewhat protracted autumn followed, during which many trees made a late growth and had not sufficiently ripened their wood at the commencement of cold weather. This was especially true of the late-growing conifers, such as Sequoias, Cryptomerias, Cupressus of various sorts, as well as pears, which in many instances were in blossom in October. Fortunately the winter, with one or two early exceptions, was a mild one, and the injury done to the immaturely-ripened wood was comparatively unimportant. Another dry summer, that of 1871, followed, causing irregular and imperfect growth, in many cases late into the autumn. On the 20th of September there came a

sudden and severe frost, late in the evening, cutting everything in the least tender to the ground, and even browning some tender tips of the late-growing evergreens. This was followed by mild weather for several weeks. But no doubt unusual disturbance took place in the circulation of many trees at this time, so that they went into their winter quarters not well prepared to resist hard weather. Unfortunately a very unusual condition of weather came on the 4th and 5th of March in the shape of hard dry cutting winds, with the mercury only four degrees above zero—at this time the ground, entirely unprotected by snow, was frozen to the depth of from three to five feet, and of course perfectly dry, thus entirely preventing all plants, during this fearful evaporation from the excessive cold winds, from obtaining the slightest assistance in the way of moisture from the roots. For the next two days there came a surface thaw and some snow which melted soon after it fell, but the ground was so hard and the frost so deep that the water remained on the surface as on a floor, freezing at night and melting by day for a week, but totally unable to penetrate the ground. The roots of the trees were held all this time as in a dry iron vice. This coming upon plants so enfeebled by the condition of the preceding two years, caused the severe damage which seems to have extended over all the middle and eastern States. The most perplexing thing is the extraordinary irregularity of the injury. Plants and trees heretofore considered tender even in the mildest winters, are uninjured, while others perfectly hardy are killed. An old beech hedge here is completely riddled; so likewise a hemlock and Norway spruce hedge; a large *Acer campestre*, twenty-five years old, killed; so is a large deciduous cypress, twenty-five feet high; another by its side uninjured; three large *Abies Menziesii* killed, though heretofore hardy in the worst season; beds of English ivy on the ground, having the protection of the warmth of the soil, killed; immediately adjacent, on a wall, hardly touched; rhododendrons generally killed back though with some green wood—those protected by wooden houses have suffered quite as much; evergreens as well as deciduous trees, standing side by side, of equal size, age, and apparent health, one taken and the other left, and yet peach trees are not only an exception, but the amount of bloom upon them is greater this year than I have ever known for twenty-five years. *Berberis*, many killed, some only partially injured; half the wood and all flower-buds of hardy azaleas killed; lindens, hardy heaths, rhodoras, and similar plants, killed; the dwarf forms of *Abies excelsa* are all killed; while *Abies Kämpferi* is uninjured; most of the pinuses have escaped; the deodars have been killed, while Cedars of Lebanon are uninjured; cypresses and junipers are generally safe, as is also the umbrella pine; *Thujopsis borealis* and *Thuja aurea* are unharmed; among things that have wholly escaped are magnolias, honeysuckles, oaks, &c. To add to our perplexity we have not only lost our trees, but we have not learned any lesson from our misfortunes. We can only regard it as an exceptional year which, like an earthquake or deluge, may never occur again, but if it should, I do not see how we can prevent the devastation, even if we knew it was coming."

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE ELONGATED CYTISUS (*CYTISUS ELONGATUS*).

This forms a wide-spreading bush, from three to four feet high on its own roots, with many long, slender villous, twiggy shoots, which, in April and May, are completely weighed down by the numerous bright yellow flowers put forth along nearly their whole length; and when grafted standard-high on the Laburnum, none of the pendulous species are more beautiful. In winter it requires to have the branches that bloomed the previous season more or less cut out, as they often get completely exhausted; but numerous young ones are produced from the base to take their places the following season, none of which should be shortened. The leaves are trifoliate, with the leaflets obovate, and clothed beneath with closely-pressed hairs. The flowers are lateral, pea-shaped, somewhat tubular, bright yellow, and usually produced in fours on short footstalks along the shoots, pods straight, compressed, nearly black, and ripe in September.

This Cytisus is a native of Hungary, where it grows in woods. It succeeds in any good garden soil, and is easily increased by grafting, or by means of seeds. It was first introduced in 1804.

There are numerous suburban gardens with lawns too small to be cut up with clumps, yet capable of accommodating a few select small trees dotted about them, and for such a purpose nothing can be more suitable than this Cytisus grafted,

standard high, on the Laburnum; it then forms a highly ornamental object on the grass, and the surface round the stem need not be left bare. *Cytisus multiflorus* and *ruthenicus* are mere varieties of this species.

Pyrus Malus floribundus.—This will be found to be a valuable addition to spring-flowering shrubs. Seen, as I have seen it to-day (April 13th), in the sheen of a spring-day sun, it is indeed "a thing of beauty," and if not "a joy for ever," at least joy for some weeks. In the bud state the flowers are a rich blue colour, passing to carmine pink, and as the bloom expands to delicate pink and white. The foliage, which appears with the bloom, is a rich dark green. When I say that the flowers are chaste enough to be employed in bouquets or as table decorations—that the plant is perfectly hardy, suitable alike for the forcing house, or the open air, and that it may be grown as a bush, a pyramid, or a standard, I presume I have said enough to induce those interested in such plants to see it and judge for themselves.—W. WALTERS.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Umbrella Pine.—Will any of your readers oblige by telling me where I may see the largest specimen of the Umbrella Pine (*Sciadopitys verticillata*) of Japan, and, if convenient, furnish me with the name of the largest specimens?—DARTMOOR.

—In reply to "Dendrophilites" (p. 572), I may assure him that this pine is perfectly hardy in the latitude of London. I am not sure where the specimens are, but there are good ones at Coombe Wool-Nurseries.—J. S.

Noble Cedars of Lebanon.—I lately visited the long-famed Cedars at Pain's Hill, and was very much struck with their dignity and beauty; but more so by the rather uncommon form of one or two of the trees. We all know how grandly diversified in habit the Cedar of Lebanon is, but its tendency generally is to spread. This makes the tree all the more valuable, because almost every other pine rushes straight to the sky, and is symmetrical in habit. One or two of the trees at Pain's Hill, however, are like the big Californian pines in the height and straightness of their enormous trunks, while not losing that picturesqueness of outline which is so marked a feature of this Cedar.—H. V.

Euonymus japonica as a Seaside Plant.—I can endorse what is said with reference to this matter at p. 573, but about its hardiness otherwise, my experience is against it. In dry places, upon rockwork, or on very gravelly soil, it will do, but a very severe winter will even then hurt it much. In cold places I do not know of any success. However, it has been introduced into gardens in England, a severe winter destroying it. I have grown thousands of the gold, silver, and green kinds, but all faro alike, when Jack Frost pinches hard. I therefore invariably protect most of my plants in winter. I find the gold, green, and silver kinds of Alaternus about the same in hardness as the Euonymus—but by all means let them all be grown near the sea. I am fifteen miles from it, due north.—J. SCOTT, *Merriville, Soveret*.

Loranthus europaeus.—In No. 17, p. 373, of THE GARDEN, Mr. Gordon suggested that you would endeavour to introduce this singular parasite from the South of Europe into this country. It is now known that Dr. Von Marius had succeeded in growing it artificially. If Mr. Gordon will be kind enough to state the name of the work in which any account can be got of this Loranthus having been propagated artificially, he will greatly oblige an OLD FRIEND.—[Mr. Gordon, to whom your query has been submitted, says that Dr. Von Marius rearranged and defined the genus *Loranthus* in De Candolle's "Prodromus," and adds that no doubt his experiments on the propagation of the European Loranthus were made some time before the Baron Jacquin's death. His own knowledge in reference to its nature and propagation was derived, he states, from a private correspondence which he had with the late Baron Jacquin, of Vienna, several years ago, when he was endeavouring to have the parasite introduced into England, but in which he failed, owing to the great length of time the berries were in the transit, a circumstance that will not arise now in these days of quick locomotion.]

FLOWER-VERSES.

BY CHRISTINA ROSETTI.

The lily has an air,
And the snowdrop a grace,
And the sweet-pea a way,
And the hearts-ease a face;
Yet there's nothing like the rose
When she blows.

Where innocent, bright-yellow daisies are
With blades of grass between,
Each daisy stands up like a star
Out of a sky of green.
The rose with such a bonny blush;
What has the rose to blush about?
If it's the sun that makes her flush,
What's in the sun to flush about?

O Wind, where have you been,
That you blow so sweet?
Among the violets
Which blossom at your feet.
The honeysuckle waits
For Summer and for heat;
But violets in the chilly Spring
Make the wood-path sweet.

THE KITCHEN GARDEN.

THE CUCUMBER—ITS CULTIVATION.

(Continued from p. 628.)

THE CUCUMBER UPON WALLS.

THOSE who have walls facing south, south-east, or south-west, and in a tolerably sheltered situation, may grow Cucumbers very successfully by training them upon such surfaces. Of course this will be more trouble than growing the plants upon the ridge, inasmuch as the training and nailing must be regularly attended to; but in such situations we have generally found we could grow the finer kinds of frame and house Cucumbers with considerable success. If the wall is devoted entirely to this kind of cultivation it will be wise to take out a trench three feet wide, and a foot deep parallel with the wall, and close at the foot. In this make a hot-bed as previously directed for the ridge, eighteen inches to two feet deep, making the dung quite firm. When the heat has subsided place a ridge of fresh soil one foot deep and eighteen inches wide close to the wall, and then fill in the excavated soil, so as to cover the dung entirely, leaving it sloping to the ground. Upon this, at three feet apart, plant properly-prepared plants, the stronger the better, and protect them for a time by a length of oiled calico or taffeta stretched out in a slanting direction against the wall. This may be supported by stakes placed so as to protect the ridge from cold rains as well as the plants from cold. It will be wise to use this protection for the first month or six weeks, in fact until the plants are thoroughly established. The after-treatment will be much the same as that given to plants upon ridges, but the training must not be neglected, or should strong winds prevail the plants will soon be irretrievably injured, if not destroyed. We have omitted to mention that it will be wise to mulch the soil with short grass, and also to thatch it as directed for the ridge.

CUCUMBERS FOR SEED.

In the above manner the Cucumber used to be very successfully grown for seed, but of late years the seasons and the habits of the plants have been too precarious to insure satisfactory results. For seed-growing, the preparation and planting will be precisely the same as before directed, but in dealing with the fruit it will be necessary that each be carefully impregnated by hand, and even then the production of seed is by no means a certainty. Impregnation is performed in this manner:—The flowers produced by the Cucumber and similar plants are sexual, that is, the flowers produced without fruit are male, whilst those produced at the end of the fruit are female. In the centre of the male flower will be seen a small mass of stamens and anthers, the latter being the parts which contain the pollen or impregnating dust. In the centre of the female flower is the pistil or female organ, through which the pollen passes, impregnating the fruit, and seed is the result. Therefore, for the purpose of impregnation, take a male flower, and stripping off its flower proper, place it firmly upon the pistil of the female flower, and there let it remain. This operation is best performed about midday, and the flowers should be those which have opened the previous day.

Some people imagine that Cucumbers will not swell unless they are impregnated, but that is a mistake, as we have cut hundreds upon which the female flower never opened at all, and consequently there could not have been any impregnation. Besides, if impregnation was indispensable to the fruit, it would be fair to conclude the production of seed must be a necessary consequence, and yet we find thousands of Cucumbers that never produce a seed at all; in fact, it is notorious that the finest formed and most perfectly-grown fruits are the least likely to do so, while, on the contrary, deformed, thick-ended fruits, not unfrequently produce seed. Reasoning from this fact, it is not unusual for growers to tie ligatures around the fruit from which seed is desired, with the impression that such cramping of the parts may tend to the production of seed. But that is a mistake. Seed, if it is produced at all, must proceed from the original impregnation of the flower, and no after external treatment of the fruit can influence its production of seed in any way. On the contrary, however, if we wish to produce seed of extra fine

quality—in fact, to improve the race of Cucumbers—we may do so by concentrating the full energy of a strong plant upon the production of three or four finely proportioned fruit. In that way increased vigour may certainly be insured to the seed produced, and it is more than probable some improved varieties may be the result of such treatment. To that end it is necessary that the seedling plant be in vigorous health, that a sufficiently healthy foliage be kept upon it, and that it be denuded of both fruit and flowers as fast as they are produced. Thus managed, good seed may be grown upon the open wall; seed, if it can only be matured upon the plant, may be superior to that ripened under glass, inasmuch as the energy of the plant being confined to the production of seed only, the seed so produced must be more vigorous than when a quantity of fruit for use is grown at the same time.

PROPAGATION OF THE CUCUMBER.

The Cucumber is propagated by seeds, by cuttings, and by layers. The first is the most general practice, but when it is desired to perpetuate a particular variety, to increase it by cuttings or layers is the most certain way of doing so. The best way of raising plants is certainly in the dung frame or dung pit, and to that end it is necessary to form a hot bed or dung pit as directed upon a former occasion. A small one-light frame is generally sufficient for the purpose, and care must be taken that the hot-dung be perfectly sweet, and the bed of sufficient capacity to insure a fine growing temperature for a month or six weeks from the time of sowing the seed. For this purpose a mixture of dung and leaves is preferable to dung alone, for they are less likely to heat violently, and consequently they retain the necessary temperature for a longer period. The bed being formed, the dung quite sweet, and the frame fixed in its place, it will be necessary to wash the glass perfectly clean, so as to command all the light possible. Then fill the frame to half its depth with sifted leaf mould, old tan, or cinder ashes, and as soon as that has attained the proper temperature, 80° to 85°, it will be fit for use. The seed must be sown in a pot of light soil, say loam and leaf-mould in equal proportions, then place it upon the soil about an inch apart and cover it half an inch deep with soil. Plunge the pot in the bed and cover it with flat glass, partly to increase the temperature, but more to protect the seed from the depredations of mice or other vermin. In three or four days, according to the age, the seed will be up, and then it will be necessary to raise the plants to within a few inches of the glass, and to keep, night and day, a gentle circulation of air. The temperature should not fall much below 70°, and may rise to 80°, with bright light and plenty of air. In raising plants it is always desirable to keep them as short and strong as possible, and this cannot be effected except by a free exposure to light, and an equally free exposure to air. When the seed-leaves, or cotyledons, have attained their full size will be the right time to single the plants out and place them in separate pots. For this purpose some warmed compost and clean warmed pots must be provided, and one or two plants, according to the kind, must be placed in each pot, the pots being of pint or half-pint sizes. Drain each pot with a little moss and some flaky leaf soil or dung, so that it may not be necessary to remove it at the time of planting. After the plants are potted they may be plunged in the frame, watered, and kept close for a day or two, shading them also should the weather be very sunny. So soon, however, as the plants have taken root, increase the quantity of air, and keep a gentle circulation by night as well as day. The plants will require washing occasionally, but the frame and plants must be lightly sprinkled once or twice a day according to the weather, and shut closely down for an hour or two, but air must be given before leaving the plants for the night. When three weeks to a month old the plants will be fit to ridge out, but if the bed should not be ready, they may be shifted into a larger pot with advantage. Be particular that they do not receive any check, as upon that much of the future success of the plants will depend.

In propagating by cuttings it is necessary to choose pieces of short, stubby growth, and not exceeding three to four inches in length. These should be cut out from the main branch, with a heel if possible, and if the main leaf be taken with the cutting it will be none the worse. Place these in

single pots, with a pinch of sand around the base of each, plunge in the hotbed, and cover with a small hand-glass. The success of a cutting depends mainly upon its being surrounded with an atmosphere which is sufficiently charged with moisture to prevent its drooping or flagging until it has formed roots which, under favourable circumstances, will generally be in from a week to ten days, sometimes much sooner. At the same time it will be necessary to dry the condensed moisture upon the glass once a day, and in very bright weather a slight shade of tissue paper will be an advantage for a few hours in the middle of the day. When the cuttings are rooted, gradually remove the hand-glass, and expose the plants to the air of the frame, until such time as the external air may be freely admitted. The shifting of the plants into larger pots, or planting them out, must be governed by circumstances, only do not on any account allow the plants to become stunted.

Propagation by layers is not much practised, but as it may be means for the amateur to procure a few plants when he has not the means of striking by cuttings, we may describe the *modus operandi*. It consists in cutting a slight gash close to a joint on the under side of a branch, and then placing it in a pot of soil, the cut part being surrounded by sand. The layer may require to be shaded for a few days at the first, but if all goes on well it will be perfect in a fortnight. Then it may be taken off, that is severed from the parent branch, and with a week or ten days' nursing will be fit to plant out.

The value of seed plants and those prepared from cuttings—layers for the present purpose being a synonymous term—are variously estimated, but it is not too much to say that cuttings come the most quickly into fruit. This is not, however, a very great advantage, as where strong plants are required early fruiting, except to a very limited extent, should never be allowed. Plants from seed, especially from new immature seed, are generally more luxuriant than plants from cuttings, and consequently do not come so quickly into fruit. For this reason it is always advisable to sow seed which is several years old, and if you have not this you may follow the custom of old gardeners and wear the seed in your trousers' pockets some weeks before sowing. This has the effect of assisting its maturation and thorough ripening, and anything that tends to that will promote its fruit-bearing properties. The question of stopping or not stopping the plants in their young state must be governed by the purpose for which they are required. If for frame cultivation trailing upon the ground, stopping is indispensable, but even then we should not stop until the young plants had made their third if not fourth rough leaf. The longer a plant goes without stopping the stronger it will get, as it will be making roots at the time it is making leaves, and will be prepared to throw strong shoots if stopped at the third or fourth leaf, but if you stop at the first leaf then there is not sufficient force in the plant to throw out a strong branch.

It should, however, be recollected the Cucumber is not a trailing plant, though we compel it to grow in that manner. Naturally, as the tendrils upon the young shoots indicate, it is a climbing plant, and therefore should be trained upon a trellis or to stakes or wire trainers. For this purpose therefore it is not advisable to stop the plants until they have attained their utmost limit, whether that limit be five feet or twenty feet. We claim to have been the first to have made this fact known when we published our first treatise upon Cucumber culture nearly thirty years ago. Since then the practice has become so general as to have formed one of the customs of all intelligent cultivators.

(To be continued.)

A.

Damage done by Trees.—At a recent agricultural discussion at Cirencester, Mr. Snowell exhibited some swedes, showing the damage done by trees to the crops. Those which had been grown under the trees were stunted in appearance, and scarcely so large as the fist; others grown in the same field, but a few paces farther from the trees, were of the usual size. These swedes were grown in a field in which there were no trees, and only three ash-trees on the site of a small ancient wood appear. Measuring out the field from the line of these trees, a space 77 links broad by 165 long, one perch of swedes growing in the middle of the space was found to weigh 34 lb., and there were 14 lb. of tops. Stepping eight yards farther out into the field, another perch of swedes was weighed, and found to yield 196 lb., and 32½ lb. of tops—showing nearly as much weight in tops as the other in swedes. The space under the trees covered 22½ acres, and as it was considered that the trees would yield a crop of three ash trees, so that for every twelve ash trees on a farm one acre of land would only yield 5,440 lb., or 2 tons 8 cwt. and 64 lb. instead of 31,360 lb., or 14 tons weight cleaned ready for sheep feed. Consequently for every twelve trees there was a loss of 11 tons 11 cwt., without reckoning the tops, or speaking roughly, a ton to every tree.

NOTES OF THE WEEK.

— FEW seem to grow any other kind of fragrant hawthorn than our own common one and its varieties. Mr. Gordon has just brought to our office blooms of the following kinds, all deliciously scented:—*Crataegus Celsiana*, *odoratissima*, *tanacetifolia*, and *Aronia*. These are all fine distinct sorts, and merit a place in every garden.

— THE famous Rhododendron walk in Windsor Great Park, says the *Globe*, is now in full bloom.

— SPRING. ENODI, a noble white Himalayan lilac, is now in fine bloom in Victoria Park, at the Hackney Wick side. Like many other hardy shrubs it is far too little known.

— LOCUSTS, it is stated, have appeared in large numbers in Bourbon county, Kentucky, and it is feared they will do great damage to fruit and other crops.

— THE deliciously-scented Magnolia Thompsoniana is now in bloom at the Fulham Nursery, where its noble white flowers fill the air for some distance around with their delightful fragrance.

— WE are informed by Mr. Wm. Thompson, of Ipswich, that he bloomed *Aquilegia aurea* (referred to in our last week's "Notes") last year for the first time in England.

— LAWS for the protection of timber trees in the United States were called into existence forty years ago to save the then rapidly disappearing live-oaks. They are needed now, says *Hearth and Home*, to save our diminishing timber of all kinds.

— THE Edinburgh Museum has just received a collection of vegetable products of an instructive character. It is intended to illustrate the ravages of destructive insects against which agriculturists, horticulturists, and foresters, have to contend.

— DR. NAPHEGI says *Hearth and Home*, recently presented to a meeting in New York a prospectus of a botanical garden for that city, which he was endeavouring to bring into existence. The idea was warmly received, and hopes of its successful accomplishment were indulged in.

— ONE of the hardy species of Lady's Slipper (*Cypripedium pubescens*) is flowering at the Wellington Road Nurseries, St. John's Wood, planted in the open border. Two other rare plants, *Cortusa Matthioli* and *Primula luteola*, are likewise flowering in the same border.

— A good specimen of the hardy palm (*Chamaerops excelsa*) is now flowering out of doors in the Royal Botanic Gardens, Regent's Park. It is planted out on a slightly raised bank, facing south, a position in which it has stood the test of several severe winters unprotected.

— A NEW botanical journal, under the title of *Journal de Botanique*, has lately made its appearance in Paris, edited by M. G. Huberson. This will appear fortnightly, and will contain original communications, translations, extracts, and abstracts of botanical papers.

— THE very curious Californian Pitcher Plant (*Darlingtonia californica*) has lived out through the winter in Messrs. Backhouse's nursery at York, and is now healthfully pushing up the quaint buds of its pitcher leaves. That it should endure our winters we quite expected, from having found it in a region where severe frost in autumn and deep snow in winter are the rule. But it is not to be expected that our summer heat is sufficient to fairly develop the plant.

— NOTWITHSTANDING the severe frosts experienced in the neighbourhood of Glasgow in the mornings during the latter half of last month, present appearances bethoken a good fruit season in the west of Scotland. The strawberry, for the successful cultivation of which that district has long been famous, has this year been most prolific in blossoming, and as far as can be judged at present, there will be a very good crop. In the middle of the season as many as 700 pints of this fruit are forwarded to the Glasgow market daily. Apples have also blown freely, but pears are scarcely so vigorous. Currants were also well flowered, but the frost has considerably thinned them.

— PRIZES amounting to £30 are offered for the decoration of the luncheon tables at Birmingham, on the occasion of the Royal Horticultural Society's show there. There will be five tables to decorate. Epergnes, &c., will be supplied by Mr. Quilter, and placed by him so as to secure harmonious arrangement. The exhibitors will consequently be required to supply only (1) flowers; (2) plants; and (3) taste in their arrangement. The tables will be ready for the exhibitors at nine a.m. on the morning of Tuesday, June 25th, and the decorations must be completed not later than twelve o'clock. The tables will be allotted in the order of application, consequently the first five will be accepted. On receiving notification of acceptance, the applicants must, as a guarantee of good

faith, deposit the sum of £2, which will be returned immediately after the tables are ready for the judges. The latter will be empowered to withhold prizes in any cases where the decoration is considered unworthy, and their decision will be final. They will be instructed to regard taste in the arrangement as the first consideration. Length of each table, fifty feet, by three feet six inches wide. The number of epergnes or flower-stands on each table is not quite settled, but will, we believe, not be less than five. There will be room on each table for about seven plants, which must be in pots not exceeding six inches in diameter. The first prize will be £10; the second £8; the third £5; the fourth £4; and the fifth £3—in all £30.

— A LARGE number of the market garden labourers of Fulham Fields, says the *Daily News*, have struck for higher wages.

— THERE is now to be seen, says a country paper, in the vicarage garden of Baldhu, near Truro, a pear tree with more than 800 pears growing upon it, looking exceedingly well and healthy—indeed, quite a picture. There are three different sorts of pears on the tree—viz., Marie Louise, Prince Albert, and Dunmore.

— THE cold and heavy rains and chilly weather which have occurred since our last, have had a bad effect on various tender crops and flower-garden ornaments, and have seriously interfered with outdoor garden work of all kinds. Many of the hardiest subjects are, however, growing vigorously, and herbaceous plants never looked better.

— MR. STEVENS, of Trentham, has got some Lady Downe's Seedling grapes preserved in bottles of water. They were cut before Christmas. The bunches that have remained longest in perfect condition are on stems of which a small portion of the base was cut away now and then. This experiment deserves to be tried on a large scale.

— AN American paper says:—"The first executive action of Mr. Greeley as President will probably be the official transformation of the White House grounds and Congressional gardens from their present superfluous subservience to aesthetics into a potato patch and field for the cultivation of all kinds of useful and palatable 'garden sass.'"

— THE committee of the House of Lords, to whom Mr. Ayrton's Epping Forest Bill was referred, after hearing the first witness, expressed a strong opinion that the proceedings of the Corporation of London against the lords of the manors should be allowed to continue, and amended the Bill accordingly. Epping Forest, therefore, appears likely to be saved, in spite of the First Commissioner of her Majesty's Works and Public Buildings.

— ANTHERIUM HOOKERI, a somewhat rare plant of the Lily family, is at present flowering freely in several places round London. The flowers are produced in a raceme from four to six inches long, and are of a showy orange yellow colour. The plant appears to thrive in ordinary soil, but the finest specimen we have seen this season is in the clayey soil of the Regent's Park.

— WE are glad to learn that Dr. Asa Gray, of Cambridge, Massachusetts, the distinguished author of that charming little book, "How Plants Grow," and of many important works and papers on botany, has lately brought out another little book, entitled "How Plants Behave," which deals with the climbing and other habits of plants, and is as likely to prove interesting to young people as the first-mentioned work.

— THE wretched weather we have recently had has somewhat interfered with the preparations for the great exhibition at Birmingham; but the work is now being carried on in good vigourously there that we have no doubt everything will be ready in good time. Mr. Harlow, who lays down the pipes for the great boiler trial at his own expense, had commenced laying them down when we called on Wednesday, and hoped to have them ready for the first trials on Friday. The great exertions of the honorary secretary, Mr. E. W. Badger, of the Messrs. Quilter (father and son), and of all others connected with this show, bid fair to be crowned with success.

— An interesting statement was made by Mr. Fallows at the monthly meeting of the Tees Conservancy, the other day. In moving the adoption of the minutes of the Works Committee, that gentleman stated that the dredging operations had been very much impeded during 1870 and 1871. From the bed of the river, twenty-seven oak trees, of sizes varying from five feet to fourteen feet in circumference and from twenty feet to forty-five feet in length, had been taken. Those trees were on the south side of mid-channel, on a clay bottom, with about two feet of sand around them. The largest tree weighed eleven tons. In answer to Mr. Hopkins, Mr. Fowler, the engineer, said that he believed the trees had grown in pre-historic times, and had drifted down from some place in the upper reaches of the river.

— We have received from Messrs. Carter & Co. flowers of the lovely blue and white *Aquilegia glandulosus*, produced true from seeds. Though it is now many years ago since this fine Columbine was first brought permanently before the public by Messrs. Grigor, of Forres, few have yet surpassed it in beauty. When obtained true to name it is certainly one of the handsomest of all hardy border flowers.

— At a sale of Orchids which took place at Stevens's the other day some of the lots fetched the following prices, viz., a finely grown plant of *Masdevallia Lindeni*, £8. 8s.; *Odontoglossum sceptrum*, £7. 7s.; *Cattleya gigas*, £6. 15s.; a *Cattleya* from the Pacific side of the Cordillera of New Granada, with white flowers edged with purple and orange, distinct in form, £6. 6s.; C. Wagneri, £5. 5s.; *Mesophipedium sanguineum*, a fine plant set with flower-buds, £6.; other lots, of which there were in all 214, fetched from £2. 2s. to £4. 4s. per lot; the total amount realised being about £190.

— THE movement for supplying flowers to the sick, to which attention has recently been paid in this country, seems to have its counterpart across the Atlantic. With the coming of the flowers, says an American paper, the charitable ladies of New York are reorganising their "Flower Mission." The intention is to supply poor patients in the hospitals with flowers during the summer months. For this purpose a depot has been established in First Avenue, between Nineteenth and Twentieth Streets, to which the ladies ask that donations may be sent. Believing the mission of flowers is to bless and cheer, these ladies carry their fragrant gifts to the bedside of the afflicted, thus infusing pleasant thoughts and a fragrant surrounding to their otherwise dreary lives.

— THE magnificent chestnut trees in the Tuilleries garden are, says the *Temps*, dying, owing to mistaken treatment which they have received from the engineers in whose charge the trees of the French metropolis are placed. The *Temps* convicts these gentlemen of two gross heresies in forest-lore. One is the neglect of lightening the earth sufficiently above the roots. The other consists in the violent remedial measures that have been employed to restore the vigour of unhealthy trees. Trenches were made round them, and filled with fresh soil, but the most important roots were cut in the process. Works of this kind have within the last few years been undertaken on behalf of the lime trees of the Luxembourg, and the plane trees near the Madeleine, which are dying as fast as they can. The moral of this is: do not employ engineers when gardeners are wanted.

London Bird-Catchers.—I have endeavoured, says the Baroness Burdett Coutts, to induce the nightingale to build its nest in my garden at Highgate with success, and it would shortly have been a welcome visitant in the neighbouring gardens; but as soon as the poor things began to sing they were trapped. Not caring to breed nightingales for bird-fanciers, I have given up the attempt; but the other pretty denizens of the air who come for shelter and roost in my trees, are equally snared by trappers; and, owing to this circumstance, my garden will shortly be left in possession of super-abundant caterpillars and other insect life, a result which has unhappily been prevalent on the Continent, and has caused serious injury to agricultural and garden produce there. I ascertained from my gardener that these bird-trappers come mostly on Sundays, during church time; and he also told me that many of the revolting practices attributed to them are founded on fact.

Vegetation in the North of Ireland.—We learn from our Belfast correspondent that the weather in the province of Ulster, and in the north of Ireland generally, has for many months been so unsuited for outdoor garden operations that the prospects of growers are anything but promising. Incessant rain, cold winds, and occasionally severe frosts, have altogether rendered the present an exceptionally bad season. The planting of potatoes, which forms so prominent a feature in the horticultural resources of the country, was delayed fully six weeks beyond the ordinary time, and even then the sets were planted under discouraging circumstances, as it had been found impossible to prepare the ground properly for their reception. The early potatoes, however, came up vigorously, but the severe frosts towards the end of May seriously affected them, and a very indifferent yield must result. If a comparatively favourable season sets in now, the later plants will not suffer from the continued rains, as the system of ridge planting adopted in this country, admits of the soil being very perfectly drained. Fruit trees, particularly apples, currants, and gooseberries, started unusually early, and consequently the young fruit was tolerably well formed before the late frosts; they have, therefore, suffered no material injury; gooseberries are very plentiful, and most other outdoor-grown fruits promise a good yield. But the entire appearance of the gardens compares unfavourably with that of former years, as the rains have precluded the possibility of bringing them under cultivation with any approach to neatness or prospect of advantage.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)
BY OUR SPECIAL REPORTER.

PRIVATE GARDENS.

Indoor Plant Department.—Conservatory climbers require more attention at this season than at any other. Fuchsias trained on rafters are being thinned, and their borders occasionally watered with manure water. The beautiful Chianthus Dampieri is now in bloom in some places, and the greatest care is taken in watering it; some raise the soil a little around the neck of the plant, so as to prevent its getting wet; others feed with water from saucers placed under the pots. Seed-pods on Azaleas are removed as soon as they appear; the latest flowered ones are repotted if necessary, and are placed in well-shaded vineeries. Camellias, Orange Trees, &c., are still kept in warm well-shaded houses and syringed early every afternoon. Pelargoniums, as they advance in growth, are staked and brought into the conservatory. In stoves, Caladiums are now in great beauty. A little weak manure water is given them now, and then, and they are also kept well shaded and in a nice moist temperature. The first flowered Gloxinias and Achimenes are now about over, and are placed on back shelves in warm houses; water being partially withheld. Such as are now in flower, are kept near the glass, shaded from sudden outbursts of bright sunshine, and in all cases the foliage is kept dry. They are also brought into cool or intermediate houses to prolong their beauty. Gardenias are kept well watered, syringed, and shaded. Aristolochias and a few other stove creepers are apt to harbour mealy bug; occasional syrings with weak tobacco water will, however, clear them of that pest. Similar applications are also effectual in preserving the young shoots of *Diospyros*, *Medinillas*, *Cyanophyllums*, &c. Cycas, Encephalartos, and other plants of that class are frequently examined, in order to liberate and keep in proper order the young fronds, that sometimes become entangled with other plants with which they are associated. Orchids receive liberal supplies of water, but no more shading in this comparatively dull weather than is absolutely necessary, unless it be to prolong the beauty of the flowers. Calanthes, which are growing strongly, are kept on shelves near the glass. Filmy Ferns, under hand-lights, enjoy a steady temperature; they are kept in the darkest parts of the fernery, and receive extra shade. Every morning, the glasses under which they are kept are rubbed dry with a cloth, and the plants are then gently wafered through a fine rose or syringe.

Pits and Frames.—These are now nearly cleared of bedding plants, and as sufficient time has not yet been spared to refill them, Alternantheras and Coleus still under cover, are therefore allowed more room. Dracaenas, variegated Abutilons, &c., are also still retained in frames. Early-flowered Calceolarias, turned out of the conservatory, if good, are likewise placed in frames to ripen seed; if desirable to retain some of the best for next year, the flower spikes are cut off, and the plants are placed in frames in front of those kept for seed. Plants of *Amaranthus salicifolius* are repotted as they advance in growth. They are kept in cold pits rather close, and are encouraged by weak applications of manure water. Petunias, both single and double, are being trained into form, and are not allowed to bloom until they have attained the required dimensions. Japan Lilies, as they form their flower-buds, are removed from pits to larger houses; they are top-dressed with decayed cow-dung and turfy loam in equal proportions, and securely staked. Plants of *Erythrina Crista-galli*, as they make sufficient growth to require stakes, are also removed from pits to larger structures.

Flower-Garden and Shrubberies.—Coniferous trees with contending leaders have all removed but the strongest one. Roses and other small shrubs affected with green-fly or thrips, are frequently syringed. Planting out summer bedding-plants has been so vigorously proceeded with for some few days back, that in many cases it is all but finished. Some of the more tender plants, however, are not yet trusted outside, but are kept well exposed in cold frames. Delphiniums and other strong-growing herbaceous plants are timely staked and secured with strong matting or rope yarn. Herbaceous borders are frequently gone over with the hoe, mulching at the same time the best plants with leaf-mould or well-decayed manure, which is afterwards covered with a little soil to give all a neat appearance. Pyrethrums required for late flowering are cut over, and are allowed to grow afresh. Annuals for late flowering are sown in shady borders in time to be transplanted where they are to bloom. Brompton, Queen, and Emperor Stocks are sown to stand through the winter. Lawns are regularly mown once every eight or ten days; weeding and cleaning walks and borders receive punctual attention. Surfacing the walks in pleasure

grounds and in geometrical flower gardens with new clean grave is being done, and afterwards well rolled.

Indoor Fruit Department.—The earliest of the Queen Pines are now colouring, the second lot is fully swelled, and others are advancing towards these stages. Suckers are taken off, potted, and plunged in the front of the beds. Where tan or other fermenting material is used, the beds are either wholly or partially renewed as the heat begins to decline, and before the next successions are introduced. Where fungi make their appearance in the beds a little fresh air-slacked lime is mixed with the fermenting material. Inside vine borders occasionally receive thorough waterings, and to those in pots waterings of weak manure are given. A little air is kept on night and day when the grapes are colouring, and a little fire heat at the same time. To Peaches and Nectarines ripening a steady gentle heat is maintained, and air is given on every favourable opportunity. The syringe is freely used in the case of late crops; thinning and tying in the shoots also receive attention. Strawberries in full bearing occupy the top shelves on the back walls of vineries and early peach-houses; the next in succession have set their fruit, but are kept in cooler houses, and the last crop for this season's forcing are placed outside in front of walls with a north aspect, or on the sides of shady walks. French Beans producing crops in early vineries are kept near the glass, but not in close proximity to the pipes, as that would induce red spider. They are frequently syringed, plentifully watered, and top-dressed as they come into bloom. Melons ripening fruit are freely supplied with air, and have all the light possible. Plants in frames are thinned and the flowers fertilized; fruits swelling are placed on slates, pieces of wood, or tiles. Cucumbers for succession are potted off singly from the seed pots, and as the old plants become exhausted, they are replaced by young ones.

Hardy Fruit and Kitchen Garden.—Fruit trees on walls are frequently syringed by means of the garden engine, and they are kept constantly tied. Young standards have all useless wood growing about their centres and on the stems removed.

Cabbages.—Some seed of these is sown for Coleworts, and as space permits fresh plantations are made. Cauliflowers are planted out as required; where the heads come too quickly for use, one of the side leaves is broken over the flower to preserve it for a few days longer. The main crop of Brussels Sprouts is being planted out two feet apart. A few Savoys are also being planted.

Spinach.—Successional sowings are made broadcast on empty spaces, or in lines between rows of Peas. New Zealand Spinach is planted out in lines two feet apart, and fifteen inches between the plants.

Peas and Beans.—For late autumn use, a sowing of tall Marrow Peas is being made, six feet between the lines, in deeply-worked soil. Another main crop of Beans is sown as required, and advancing crops are earthed up and topped. As the last sowing of French Beans appears above ground, another sowing is made.

Celery.—Plants in frames have the sashes removed, and those in beds are never allowed to become the least dry.

Root Crops.—These are hoed and thinned as they advance in growth. The main crop of potatoes is being earthed up. A sowing of Onions is being made to succeed that sown a few weeks since, for salads.

NURSERIES.

Indoor Plant Department.—Young Palms are being shifted as they fill their pots with roots; seed of the various kinds is sown as soon as obtained. Crotons enjoy a moist temperature; they are plunged in coco-nut fibre, and are kept near the glass; where good colour is more aimed at than rapid growth, the roots are kept somewhat confined as regards pot-room. Where Sonneratia margaritacea is grown in pans, the young growths are pegged down; thus treated, they form roots freely at the joints, and are in due time separated and potted singly. They are kept in moist shady stores or in Orchid houses. Various kinds of Eranthemums and other plants of that kind receive similar treatment. Pitcher Plants are kept in moist warm houses, frequently syringed, and well supplied with water. Unless the soil is of a very porous character, Pitcher Plants soon exhibit signs of debility, therefore, as soon as such becomes visible, they must be shaken out and potted in a mixture of rough fibrous peat and chopped sphagnum. Marantas are kept in moist, warm, shady houses, and in some instances on stages over water tanks; as they fill their pots with roots they receive another small shift. Seedling Anthuriums of different kinds are potted singly into thumb pots, and the weakest are pricked out into pans. Poinsettias are shifted into four-inch pots. Rhododendrons and Azaleas in pots have their flowers removed as

soon as they begin to fade, and every encouragement is then given to the plants to induce good growth. New Zealand plants in flower are removed to the front stages of show-houses, or any other place where they can be kept cool and well aired. Where Succulents require to be increased, well-matured leaves are separated from the parent plants and are inserted in pots of light compost surfaced with silver sand. Four small pegs are stuck into the pots near the edges, and a piece of matting is tied round, so as to serve as a support to the leaves; the pots are placed on shelves in intermediate houses, or in cold frames kept rather close. Orchids in flower are removed from the house in which they were grown, to a cooler and drier atmosphere. Imported plants are spread out for a time on shelves, where they are allowed to break naturally; those that have made considerable advancement are either potted or placed on blocks, according to their requirements. Anacanthus are now growing freely, and great attention is bestowed on them in the way of shading and maintaining a steady temperature. The bell-glasses placed over them are tilted up a little throughout the day, and taken off and wiped every morning. Young Ferns as they require it are shifted into larger pots. In order to allow the young fronds more fully to develop themselves, some of the oldest ones are removed. The finer kinds of Selaginellas are being increased by means of pieces, to which rootlets are attached; they are inserted in pots or pans of light sandy soil, and are kept well watered and shaded.

Outdoor Department.—Cleaning the ground now constitutes the chief part of outdoor work. Beds of seedling Conifers are frequently gone over, and cleared of weeds. Beds occupied last year by seedling Elms, which were transplanted this spring, are producing another crop, which will be left in the beds until next spring. Elms generally keep coming up for two years after being sown. Young fruit trees receive timely attention in the way of training. Rose stocks for budding on have the young shoots shortened and regulated. Herbaceous plants are being increased by means of young shoots, which are slipped off, placed in frames, and well shaded for a time. Hollyhocks are also increased by means of young shoots inserted in cold frames. Double-flowering Rocket has their shoots layered, fixing them down with pegs, and covering slightly with soil; thus treated shoots soon spring up from every eye, and when a few inches long they are either separated and treated as cuttings, or their rooted stems are cut into as many pieces as there are joints, preserving a short piece to each cutting.

MARKET GARDENS.

NOTWITHSTANDING the unfavourableness of the weather, vegetable crops still look flourishing. Lettuces this season have been excellent, and there has been a great demand for them; they fetch about eight-pence a score. Old crops of Leeks are being cleared off the ground, the flower spikes and the points of the leaves are cut off before sending them to market. Hyacinths and other bulbous plants grown for cut flowers are now forked out of the ground and the bulbs laid on mats prior to storing them away. On the space occupied by these bulbs, lines are drawn two inches deep, in which Gherkins are sown, the seeds being placed four inches apart. In warm sheltered situations where the earlier crops of Lettuces had been raised, the ground is loosened by means of a three-pronged hand, and is cropped with Gherkins. New Zealand Spinach is planted a foot apart in shallow drills, between the rows of young Rhabarb. Fresh air-slacked lime is scattered over the plantations of French Beans and Lettuces, and slugs are this season rather troublesome.

Red Cabbages planted early in the season, in lines from three to four feet apart with intervening crops, now require all the space, and the crops are being removed. Ground occupied by early crops of Spinach has all the refuse removed to the rubbish heap, the soil turned over, and Brussels Sprouts planted in lines two feet apart each way. In rather open spaces under fruit trees, lines of Potatoes have been planted $2\frac{1}{2}$ feet apart, and are now earthed up. In the hollow lines between the potatoes, rows of Savoys and Brussels Sprouts are planted fifteen inches apart. The third Cauliflower crop, planted $2\frac{1}{2}$ feet apart, with a line of Lettuces between each row, now requires all the room it can get; the Lettuces are therefore removed for market. Seedling Cabbages, &c., are securely tied to stakes.

Spinach sown broadcast under trees, where coming up too thickly is gone over and thinned. This crop under shade seldom, however, requires any thinning or weeding. The last sown onions are being cleaned, thinning is not much resorted to in this crop, as the plants are drawn young. Lines of the same sown between Moss Roses and young newly-grafted trees are being cleaned and thinned the second time. Transplanted ones have all flower-spikes removed. Leeks grown between lines of Strawberries are removed for market, and the ground is being thoroughly cleaned and some litter placed around the Strawberry plants.

[JUNE 15, 1872.]

SOCIETIES, EXHIBITIONS, &c.

THE GREAT BIRMINGHAM EXHIBITION.

The visit of the Royal Horticultural Society to Birmingham bids fair to be a most successful one. It is to be opened, as our readers are aware, by Prince Arthur, who is a member of the Council of the Society. The official programme for the show week is now nearly complete, and will, we believe, be found to be very much as follows:—The exhibition will be opened for the public at one o'clock on Tuesday, the 23rd instant. Holders of tickets will be admitted to the ornamental gardens at the Lower Grounds before that hour, probably at eleven o'clock, but not to the show grounds, as the work of judging will be in progress.

At half-past one o'clock, the Prince will be entertained at a public luncheon which will be served in a large marquee, to be erected on the bowling-green, near the hotel, over which the Earl of Bradford, chairman of the local committee, will preside. A raised table will occupy one end of it, and there will be five others at right angles thereto. The tables and places will all be numbered, and as each ticket will correspond with one of the seats, the guests will experience no difficulty in finding the places allotted to them. The charges for the luncheon are, gentlemen, twenty-one shillings; ladies, sixteen shillings. In order to insure the tables being decorated in a suitable manner, the local committee have offered five prizes, amounting to £30, for the floral adornments of the tables. Applications for luncheon tickets, accompanied by remittances, must be sent to Mr. A. Forrest, 10, Cherry Street, Birmingham, not later than the 13th instant. As the number to be allotted is limited, early application on the part of those who desire to secure places is necessary.

It is hoped that Prince Arthur's engagements will allow his Royal Highness to visit the exhibition on Wednesday, the 26th, and present the gold medals to the recipients. At four o'clock in the afternoon on Wednesday, the Horticultural Congress will commence its sittings. It will be presided over on the first day by W. Wilson Saunders, Esq., F.R.S., and the proceedings will be commenced with an address "On Recent Progress in the Scientific Principles of Horticulture," by Professor Threlfall Dyer, F.L.S. Afterwards various papers will be read, and discussion on them will take place. There will be no charge for admission to the congress, which will be open to all visitors to the show.

On Thursday, the annual Birmingham show of roses will take place; there will also be a fresh competition in the fruit classes. In the afternoon the second and final sitting of the congress will take place, under the presidency of the Earl of Bradford. The introductory address on that occasion will be delivered by Thomas Moore, Esq., F.L.S., the subject being "The Recent Progress of Practical Horticulture." As on the former day several papers, each limited to a quarter of an hour will be read, and will be followed by discussion.

On Friday and Saturday there will be additional competitions in cut flowers and bouquets. Of course it is at present impossible to give any idea of the number or extent of the entries; all that we are able to state is that they are most numerous, as may be inferred from the fact that in one class alone they necessitate the erection of a special tent 160 feet long by 20 wide.

The department of horticultural implements, ornaments, and appliances will be very extensive and interesting. The placing by the committee of three gold medals at the disposal of the judges for horticultural buildings has had the effect of stimulating competition, and there is good reason to anticipate a display in which many descriptions of structures will find a place, and in which, moreover, some novelties will be included. A number of them are now in course of erection, and the whole must be completed, ready for inspection, by Tuesday next, the 18th instant. Garden furniture, wire-work, and decorations, for each of which a gold medal is offered, will also constitute a prominent feature. The committee undertook an arduous task when they resolved to subject the heating apparatus to practical tests upon the ground; but owing to the friendly advice and support accorded to them, the arrangements are proceeding satisfactorily. The estimated expense was, in the first instance, so considerable as to present obstacles well-nigh insurmountable to the carrying out of that portion of the programme; but through the liberality of one interesting exhibitor, who was anxious that the trials should take place, those difficulties have been surmounted. In this respect the committee will, no doubt, confer a great benefit upon the horticultural public, by whom the results will be eagerly looked for, more especially as several newly-patented inventions will be exhibited for the first time. One thousand feet of piping has been provided; and twelve boilers, capable of heating that quantity, with others of only half the capacity will be tried; while gas stoves, and other portable contrivances for effecting the same purpose will also be shown. The makers of garden machinery will muster strongly, and although garden implements will not be so plentiful as they ought to be in a district where they may be reckoned among the staple industries, they will, nevertheless, be efficiently represented. As we have before explained, the committee having no experience to guide them in the preparation of their programme, it is, necessarily of a tentative character; but we would fain hope they will succeed in the object they have in view—that of laying the foundation of a department which will hereafter bring the manufacturing skill of the country into more intimate relations with horticulture.

RAILWAY ARRANGEMENTS.

The railway companies have been most liberal in their arrangements. Excursion trains will run as under:—

The London and North-Western Railway Company from London to Birmingham, on Saturday, June 22nd, returning on Thursday, June 27th.

From all principal Northern stations in Lancashire, Cheshire, and Yorkshire, on Monday June 26th, returning on Friday, June 29th.

On Thursday, June 27th (One Shilling day), day trips from Northampton, Blisworth, Weedon, Rugby, Stamford, Market Harborough, Leicester, Nuneaton, Coventry, Loughborough, Kineton, Denby, Burton, and Lichfield.

On Friday, June 28th (One Shilling day), day trips from Liverpool, Warrington, Hesford, Crewe, Manchester, Stockport, Alderley, Chester, Beeston Castle, Shrewsbury, Wellington, Newport, Stafford, Ac.

On Saturday, June 29th (Sixpenny day), day trips as follows:—

By the Great Western Railway Company, on Thursday, June 27th (One Shilling day), from Shrewsbury, calling at principal intermediate stations to Abberbury, Moreton, Leominster, Warwick, Kingswood, and Knowle; from Stourport, Wimbley, Brierley, Oldswerton, and Hatton; from Worcester, Dursley, Kidderminster, and Stourbridge.

On Friday, June 28th (One Shilling day), from Oxford, and all intermediate stations, to Harbury inclusive.

On Saturday, June 29th (Sixpenny day), from Worcester, Droitwich, Kidderminster, and Stourbridge; from Leominster, Warwick, Kingswood, and Knowle; from Stourport, Wimbley, Claverdon, Bearley, and Hatton.

By the Midland Railway Company, on Thursday, June 27th (One Shilling day), from Derby, Nottingham, Loughborough, Toton, Ilkeston, and stations, on days to be announced.—Bath, Bristol, Stone, Gloucester, Cheltenham, Tewkesbury, Worcester, Droitwich, Bromsgrove, Evesham, Alcester, Redditch, Rotherham, Sheffield, Chesterfield, Belper, Manchester, Buxton, Bakewell, Matlock, Lincoln, Newark, Nottingham, Derby, Burton, Tamworth, Peterborough, Stamford, Oakham, Melton, Bedford, Wellington, Kettering, Market Harborough, Leicestershire, Tockley, Nuneaton.

By the North Staffordshire Railway Company:—An excursion train from the Potteries, on Thursday, June 27th.

The particulars of dates, times, and fares will be set forth by the several companies in advertisements and bills, in course of issue.

Ordinary return tickets to Birmingham, issued by either of above-named companies, on Saturday, June 22nd, and following days, will be available for returning on any day up to and including Monday, July 1st.

While, as will thus be seen, ample arrangements have been made for the accommodation of visitors, the comfort of exhibitors has also been carefully considered. The railway companies will convey all plants, &c., to and from Birmingham at a single rate for the double journey. Small packages of plants and flowers, &c., sent as parcels, will be delivered from the several railway stations to the show grounds free of charge. A breakfast will be provided for the exhibitors on the Tuesday morning. Daily, during the continuation of the show, except on the first, a hot dinner will be served, at a time to be announced, the charge for which will be moderate; the chair to be taken each day by some well-known horticulturist. A cold dinner will be provided in the assembly-room (which will be converted into a coffee-room during the show) for those who prefer it. Mr. Quilter has set apart one of his rooms for letter-writing and appointments, and the local committee will supply them with stationery and newspapers.

It now only remains to again draw attention to the arrangements as to admission. The charges for the first day will be 10s. 6d.; or by tickets purchased not later than June 22nd, 7s. 6d.; second day, 2s. 6d.; third and fourth, 1s.; last, 6d. For one guinea may be purchased for first day, and 1s. for second, which are available on either of the subsequent days. For 10s. 6d. may be purchased a pass entitling the owner to admission during the whole of the week. Fifteen 1s. tickets may be purchased for 10s. 6d.

MEETINGS FOR THE ENSUING WEEK.

WEDNESDAY, JUNE 19.

Royal Botanic Society.—Summer Exhibition (19th and 20th), 2 p.m.

Royal Horticultural Society.—Exhibition of Flowers.

Brighton Horticultural Society.—Roses, Fruits, and Pelargoniums (19th and 20th).

Horticultural Club.—Meeting in Anderson's Hotel, Fleet Street, E.C., 6 p.m.

THURSDAY, JUNE 20.

Linnean Society.—Meeting.

FRIDAY, JUNE 21.

Royal Microscopical Society.—Lecture in museum, 4 p.m.

SATURDAY, JUNE 22.

Royal Botanic Society.—Meeting for Election of New Fellows and general business, 3.45 p.m.

Crystal Palace.—Annual Exhibition of Roses.

Land in Texas.—A Texan tells this story of lost opportunities:—"Now, you see," said he, "land was cheap enough at one time in Texas. I've seen the day when I could have bought a square league of land, covered with fine grass and timber, for a pair of boots." "And why didn't you buy it?" asked his companion. " Didn't have the boots," answered the Texan.

The Weasel and the Gardener's Friend.—Of all people in the land gardeners have most reason to protect the weasels. They have not one single word of complaint against it, not even for disturbing the soil of the flower-beds. Having no game to encourage, they may safely say to it, "Come hither, little benefactor; take up thy abode amongst us. We will give shelter to thy young ones and protection to thyself, and we shall always be glad to see thee." And fortunate, indeed, are those horticultural inclosures which can boast the presence of a weasel; for whilst the weasel stands sentinel over the garden-ordinary, and of little cost are the apartments required for it. A cart-load of rough stones heaped up in some sequestered corner free from dogs, will be all that it wants for a safe retreat and a pleasant dwelling. Although the weasel generally hunts for food during the night, it is by no means indolent in the day-time, if not harassed by dogs or terrified by the report of guns. Whilst all is still around you, it may be seen coming out of a hole in the ground, with its head particularly erect at the time, and it starts and stops at intervals as though afraid to advance.—Charles Waterton.

THE SHAKER ORCHARDS AT NEW LEBANON.

A CORRESPONDENT of one of the American papers, who has recently visited the Shakers at New Lebanon, gives the following account of the management of their orchards :-

"Shaker soil and locations are," he says, "in reality, no better than the soil and locations elsewhere, especially at Mount Lebanon on the cold side of a very high mountain and pretty high up on its sides; there the winds sigh mournfully and the storms beat with fury and the surplus rains wash—sometimes in a way really vexatious to the patient and persevering cultivators of the soil. How they succeed so well when others fail in fruit-growing is a matter that may properly seek investigation. The conclusion of the whole matter is, that they value their fruit trees and take all necessary care to keep them in health and productiveness. To do this, the ground is thoroughly prepared for the orchard before the trees are set. With them, thorough drainage stands first in preparing land for any crop. Next, a thorough and deep tillage, with the application of composts of manure, lime, or ashes. The manure heaps, while in course of preparation, are enriched with soap suds and other wash from the buildings, forming tree food of excellent quality. They usually raise their own trees from the seed of choice varieties, which at a suitable age, are budded or grafted, from known and approved sorts. In short, they make themselves sure of good trees by raising them among themselves. Sometimes their supply of these trees exceeds the home demand and then he is a lucky fellow who can obtain their surplus. I lately visited one of their orchards, raised and managed as I have described, and it presented an appearance of vigorous growth. Though the crop of apples fell considerably short of last year, the harvest of pears was enormous. When I was there, late in October, they were loosening the soil around the trees and applying the top-dressing.

"Nothing of a fertilising nature is lost with the Shakers. One very fine orchard, which is on descending ground west of the buildings, has iron pipes, which convey all the wash and deposit into a huge cistern on the upper edge of the orchard. Here is deposited a rich amount of liquid fertilisers, ready for use when needed by drought or otherwise. From this cistern troughs can be laid to carry the liquid to each tree, and be distributed among all. It will be seen that fruit-growing as practised among this people requires labour and thought. And now the question comes up, *does it pay?* The answer they give, is, that it does pay, and pay well for the capital invested and labour performed. And the why it does pay is, that from growing the seed to the full-bearing tree everything is done in that thorough, careful manner which must insure success."

OBITUARY.

WE regret to announce the death of Mr. Rose, gardener to her Majesty, at Frogmore, which took place on the 5th instant, from inflammation and congestion of the lungs. Mr. Rose was gardener at Floors Castle previous to being transferred to Windsor to succeed the late Mr. Ingram. Mr. Rose was an amiable man and an accomplished gardener, and his many friends will regret that he was cut off so soon after succeeding to one of the highest prizes open to British gardeners.

WE have also to announce the death of Mr. Emmanuel Sage, late of Gopsall Hall Gardens, and who has been for some time in business for himself at the Atherton Graperies. He was an able and enthusiastic gardener, and is deeply regretted by all his brother gardeners who had the pleasure of his acquaintance. He died comparatively young, and leaves a youthful family to mourn his loss.

The death is likewise announced of the Rev. William Ellis, the well-known missionary in the South Sea Islands and in Madagascar, which took place on the 9th instant at Rose Hill, Hoddesden. He was born in 1795, and in early life became connected with the London Missionary Society, under whose auspices he went out to prosecute his labours abroad. He was fond of plants and plant culture, and his fine collection of Orchids, which were only sold at Stevens's a few days ago, was well-known to all connected with gardening. The singular Lattice-leaf plant (see p. 565) is one of his introductions from Madagascar, and he was also instrumental in introducing several fine specimens of Angraecum. He has published "A History of Madagascar," "Vindication of the South Sea Missions," "History of the London Missionary Society," and several other works. He was buried in Abney Park Cemetery yesterday.

Paper Manufacture.—The Chinese are said to have made paper, from pulp artificially prepared, at the commencement of the Christian era; and they and the Japanese are still said to be the most skilful paper-makers in the world.

COVENT GARDEN MARKET.—June 14th.

Flowers.—These consist of small, finely-blossomed Hydrangeas, Heaths of various kinds, Petunias, double and single; zonal, show, and other Pelargoniums; and compact, well-bloomed plants of herbaceous Calceolarias. There are also Gardenias in pots, Japan Lilies, five-leaved Begonias, small Dracaenas and Palms, besides many Ferns and Club-mosses. Cut Flowers comprise spikes of Acris odoratum, and many other kinds of Orchids, sprays of Stephanotis, blooms of Edelharts, and other tender plants; also Iris, Sparaxis, and other Cape bulbs, various kinds of pink Delfphiniums, double Rocket, and an abundance of Moss Roses.

Fruits.—Indoor fruits, such as Queen Pines, White and Black home-grown Grapes, Figs, Peaches, Nectarines, Strawberries, and Cherries, are plentiful. Of Cucumbers and Melons there is no scarcity. There are also several baskets of very fine Tomatoes.

Vegetables.—Home-grown Green Peas have been in the market for some weeks. These come in round hampers covered on the top with short grass, kept in its place by means of cross-pieces of stick. As soon as they come into market the baskets are for the most part opened; women are set to work to shell the peas, after which they are sifted so as to remove all small ones. There are also good examples of Globe Artichokes and New Potatoes. Cauliflowers are furnished by wagon-loads, as are also Cabbages tied round the middle with pieces of matting. Great quantities of Lettuces are exposed for sale every market day. When sold, the ties by means of which their hearts were blanched are cut off, and the roots and some of the roughest outside leaves are removed. French Beans are also plentifully supplied, and Longpod Beans have also made their appearance. Transplanted autumn-sown Onions, and also those of the same sowing pulled from the seed-bed, early ones from the February sowings, in frames, and the earliest spring outdoor sowings, are all now brought plentifully to market. Radishes are still grown, but in less quantities than they were earlier in the season. Salads, in the form of Mustard and Cress, are sold in small punnets. Turnips, some two and three inches in diameter; Carrots, both old and young; Horseradish in small bundles, the roots an inch or more in thickness; and, old heads of Beetroot, may all be had. Spinach is brought in by the hamperful and blanched. Asparagus heads are likewise abundant.

PRICES OF FRUIT.

J. B. BROWN & CO.

Offices—90, CANNON STREET, LONDON, E.C.; Netting Warehouse and Factory, 4, LAURENCE POUNTNEY PLACE (close to the Offices).

ROCKWORK in PICTURESQUE and NATURAL forms for FERNERIES, CONSERVATORIES, ALPINERIES, HEATHERIES, WATERFALLS, CLIFFS, BANKS OF STREAMS, PONDS, LAKES, CAVES for BOAT HOUSES, AVIARIES, AQUARIAS, &c., with plenty of soil in, and on the ledges, between the strata and crevices of the rock, so that all get moisture, under the protection of the rock, Alpine, or other Rock Plants, and Shrubs, to grow naturally about the Rocks. Using generally stone or other materials of the locality. Unearthed Rock broken into picturesque forms, where it is to be found.

Executed by men who have grown up at it; some of them nearly twenty years, under my instructions, JAMES PULHAM, Broxbourne, Herts. Propects for one Stamp, with list of references recommended by the principal Landscape Architects of the day.

LONDON DEPOT for ROCK or VARIOUS STONE, also Superior TERRA-COTTA GARDEN EDGING, and KERB of various Geometric plans for CONSERVATORIES and Jardinette Borders; VASES, FOUNTAINS, &c., to be seen at—
5, MARIA PLACE, NEAR LOUGHBOROUGH-ROAD STATION, BRIXTON, S.E. (Eighteen minutes' Journey from Victoria Station.)

THE ROCK PART of the SCENERY in the OAK LODGE and BERRY HILL GARDENS, which have been so commended in this Journal, was executed by JAMES PULHAM, Broxbourne and Brixton, in the years 1859 and 1864, for picturesque effect. See illustration in the number for December 30, 1871.

GREEN'S PATENT ROLLERS FOR LAWNS, DRIVES, BOWLING GREENS, CRICKET FIELDS, and GRAVEL PATHS.

Suitable for Hand or Horse Power.

Illustrated Price Lists Free on Application.
THOMAS GREEN & SON, Smithfield Iron Works, Leeds, 54 & 55, Blackfriars Road, London, S.E.

SPLENDID SILVER-SAND direct from Pits, at 9s. 6d. per Ton. Delivered on rail at Leighton Station, North-Western Railway, free at best quality PEAT for Sale.

JAMES FRASER & CO., SAND MERCHANTS, LEIGHTON BUZZARD, BEDFORDSHIRE, will be glad to forward Samples (on receipt of 1d. stamp of 1d.) of their BEWFORDSHIRE SILVER-SAND. This Sand is now acknowledged to be the best obtainable; very sharp and clear; for propagation and plant purposes nothing can surpass it.

TANNED NETTING for GARDEN PURPOSES. Protecting fruits from Birds, &c. Widths, 1, 2, 3, and 4 yards. Price one penny per square yard.—HOOPER & CO., Covent Garden, London, W.C.

TANNED GARDEN NETTING, One Penny per square yard, for Protecting Seeds, Beds, Peas, Fruit, Strawberries, &c., from Birds, Frost, Blight, &c., and as a Fence for Fowls, in 1, 2, 3, and 4-yard widths. HEXAGON TIFFANY, and other NETTING, Galvanized WIRE NETTING, PEA HURDLES, and SEED PROTECTORS, by C. WRIGHT & CO. (late 376, Strand, London), Newark-on-Trent.

NETTING for FRUIT TREES, SEED BEDS, RIPE STRAWBERRIES, &c. TANNED NETTING for protecting the above from frost, blight, birds, &c., two yards wide, 3d. per yard, or 100 yards, 20s.; four yards wide, 6d. per yard, or fifty yards, 20s. NEW TANNED NETTING, suited for any of the above purposes, for Protecting Fowls, two yards wide, 6d. per yard; four yards wide, 1s. per yard. Can be made in any quantity of EATON & DELLER, 6 and 7, Crooked Lane, London Bridge, E.C.

THOMAS'S IMPROVED PEA TRELLISES, Galvanized after Made.

6 feet wide, 3 feet high 3s. each
6 feet wide, 4 feet high 4s. each
6 feet wide, 5 feet high 5s. each

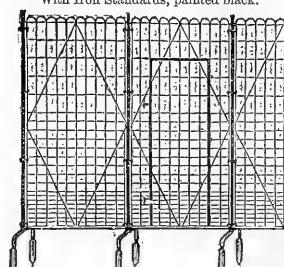

IMPROVED FRAMED STANDARDS,

For ditto, 2s., 2s., 6d., and 2s. 9d. each.

IMPROVED PEA & SEED GUARDS,

Galvanized. 3 feet long. Price 9s. per dozen.

THOMAS'S NEW POULTRY FENCING, GALVANIZED AFTER MANUFACTURE, With Iron Standards, painted black.

This ornamental fencing is easily fixed or removed. The Iron Standards are 3 feet apart; the Galvanized Wirework can be had separately, for attaching to wood uprights, at one-fourth less price.

PRICE:—6 feet high, 6s. 6d. per yard; 7 feet high, 7s. 6d. per yard.

Delivery charged 4s. extra, excepting when 12 yards are ordered, in which case a door is included, and carriage paid to all principal railway stations.

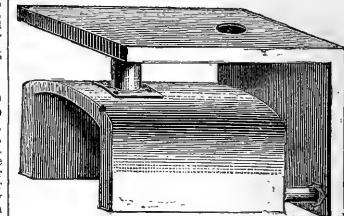

Orders for the above, value 40s., Carriage Paid to the principal Railway Stations in England.

Full Illustrated and Descriptive Catalogues of Wire Netting, Fencing, Pea Trellises, Garden Articles, Flower Stands, &c., on application.

PADDINGTON WIREWORKS,
285 and 362, EDGWELL ROAD,
LONDON, W.

JONES'S PATENT

"DOUBLE L" SADDLE BOILER.

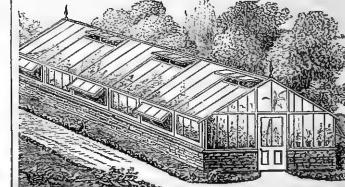

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements, viz., the water-space at the back and over top of saddle, increases the heating surface to such an extent that a PATENT DOUBLE L SADDLE BOILER will do the same work with less quantity of fuel; the cost of setting up is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron, are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Fect.	£ s. d.
20 in.	18 in.	18 in.	300	7 0 0
20 "	18 "	24 "	410	7 0 0
20 "	18 "	30 "	530	8 0 0
24 "	24 "	24 "	700	10 0 0
24 "	24 "	30 "	830	12 0 0
24 "	24 "	36 "	1,000	14 0 0
24 "	24 "	48 "	1,400	18 0 0
28 "	28 "	60 "	1,800	22 0 0
30 "	30 "	72 "	2,600	30 0 0
36 "	36 "	96 "	4,500	50 0 0
48 "	48 "	108 "	7,000	75 0 0
48 "	36 "	144 "	10,000	100 0 0

And are kept in Stock and sold only by the Inventors and Patentees, J. JONES & CO.

Price Lists of HOT-WATER PIPES and Connections, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES & SONS,

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—Shakespeare.

THE SIX OF SPADES.

CHAPTER XVII.

Mr. Chiswick on "Bedding Out."

GENTLEMEN, said Mr. Chiswick, *Aesop* does not tell us whether thirteen respectable frogs held a coroner's quest over the remains (which must have been collected and arranged with difficulty) of that ambitious sister who, foolishly essaying to represent to her family the grand proportions of the ox, induced a sudden disruption of the cuticle, or, in the vulgar parlance, *bust*. If such an inquiry was made, the frogs—our esteemed progenitors according to the Darwinian theory—may probably have enjoyed, as we do, the rich blessing of trial by jury, and they could only have anticipated the verdict which the colliers in a wild mining district pronounced more recently upon a terrible virago who had fallen down a shaft, with the assistance of her husband—to wit, that it "served her right." Although the bereaved family—the brothers and sisters, for anything we know to the contrary of the ill-fated flirt, who perished so suddenly in the bloom of her youth and in her opera hat—had pleaded with tears for a verdict of rancicide, and a big dead-on-and the ox, no honest frog could have forgotten for a moment the plain demands of duty.

And yet, my brother Spades, it has been not seldom affirmed in my hearing by several horticultural frogs, who have burst themselves, that is to say, have completely ruined their gardens by extravagant efforts to reproduce, for their neighbours' astonishment, the outlines of a certain modern ox, known to us by the name of "Bedding Out," that their dissolution was murder, and not suicide. "See," they have cried in the crisis of evisceration, in their anything but happy dispatch, "how this detestable monster has ruined our little plot, broken down our flowering shrubs, crushed our herbaceous plants, and left us nothing, in place of our sweet unfailing beauty, but a brief and scentless glare." The very men who hacked down and uprooted their Laburnums and Lilacs, and Weigelas and Pyrus, and Berberis and Ribes, with all the energy and exultation of backwoodsmen, who sentenced their old herbaceous favourites to transportation for life, and rejoiced to consign them, packed like convicts in crowded wheel-barrows, to penal settlements in the kitchen garden—I have heard them, and so have you, plaintively protesting against their own free act and deed, as though it had been done at point of bayonet, and as though every hesitation and entreaty of theirs had only been answered by an extra prod. The fact is, that in this matter of Bedding Out, a large number of our brotherhood have felt, with good reason, ashamed of themselves—ashamed of having sacrificed and slighted so much that is beautiful, from a foolish ambition, which they could never realize, to produce sensational effects, and, like naughty dogs, who deserve, but dislike, castigation, they will creep through any hole in the fence to keep out of range of the whip.

I mean, in plainer English, that the system of Bedding Out is a grand discovery, a charming ornamentation and additional grace where it can be appropriately introduced and amply provided for; where it can be well done in a suitable site, and where it comes without trespass or ejection, as an ally and not as an opponent; but that in a small garden, where it destroys, or even interrupts the natural succession of hardy plants and shrubs, it is a very sad mistake—a mistake, which, by abusing and misapplying a beautiful branch of horticulture, has brought it into disrepute.

Where shall we find, for example, a more pleasing conformity than in the tasteful bedding-out of those terrace gardens which surround so many of our great castles and mansions, and in which architecture and horticulture are combined in such graceful union; the stone walls and balustrades, and edgings of the beds, contrasting so effectively with the bright colours of leaf and flower? and this, moreover, for eight months in the year, from March to October, if the gardener be an artist, with means and with men to realise his art, and to maintain in continuous beauty that bright mosaic basement.

What, on the other hand, more dreary or wasteful than a small garden, treeless and flowerless for two-thirds of the year? A garden did I say?—a grass plot the rather, diversified by patches of bare brown earth, the work, it might be, of a school of moles who were studying geometry beneath.

I may be asked here, why assign eight months of beauty to the garden on the rich man's terrace, and only four to the garden on the poor man's lawn? The answer is, because when the garden is small, the resources, as a rule, will be small also, restricting the supply to those plants which flower during the summer months. Bedded out in May, these will attain their charms in July, and retain them probably for the period named. But where the material is unlimited and the culture skilled, the spring flowers will be gay in March; and on their removal the introduction of blooming and foliage plants, more advanced than those which are grown where glass is less abundant, will produce an immediate and effective display.

And chiefly, I would protest against the exclusive appropriation of a small garden to that which may be termed the summer system, not only because it brings with it the miserable nakedness, the long, dreary, dirty desolation, to which I have referred, but withal a result yet more deplorable. It destroys the poetry, the sentiment, the teaching, the associations, the memories, and the hopes, of which a garden should be the haunt and home. Great poets have written tender poesy upon the brightness and sweetness, the grace and the peace, of a garden, as it used to be. They rejoiced to watch, here in cool grot, or there from the sunny walk, the natural development of its beauty—from the first snowdrop in spring to the last rose of summer, so varied, so ample, and so sure. They sang, like the birds, heart-music, from its fragrant bowers; but who has sung or can sing in or concerning those treeless, shrubless, exposed and shadeless squares, to which the blackbird comes only for his worm, and flies to seek in some more favoured garden a twig on which to chant his grace? The Muse can only weep and wail, because the Muse must be aware that Flora, whom she loves, is here but decked and exhibited to catch the public eye, and behind the scenes she is starved and beaten? The Muse is aware that for a considerable portion of the year herbaceous ghosts, arboreal apparitions, and bulbous bogies, haunt this now gaudy ground. She is not to be deceived, my brother, no more than you or I when we see some silly wench on a Sunday with half a year's wages on her back, and a month's ditto on her shining hair, as full of oil as a salad, and know that to-morrow she will be a shipshod slob, indolent, morose, and grimy.

I have one more gun to discharge against this abuse of the bedding-out system, and then I will cease firing, and speak in commendation of its use. I denounced it, where it has a monopoly, as destructive of sentiment and of amiable associations. Let me tell you an incident which happened within my observance, and which condemned it in my eyes and in the eyes of one yet more nearly interested, as the desecration of an English home. Some years ago, I held the situation of under-gardener at a country place, where an old-fashioned garden, full of beautiful shrubs and plants, was suddenly sacrificed to the fashion of the day and the bad taste of the owner, cleared, levelled, laid out in an elaborate design, and dedicated to the summer system. In the following year, a sailor-son of the family, who had been at sea as a midshipman, came back from his voyage, and soon after his arrival was brought into the garden to see "the improvement." I happened to be there at work; and as the beds were very gay, and glowing with scarlet, purple, and gold, I expected to hear great admiration. Only a sigh came from his lips, and I saw in his face a sore distress. Afterwards he came to me, and confided, for we were mates in the cricket-field, and I had carried his landing-net many a time: "Frank, I couldn't have believed that they could have shaved,

and hacked, and tattooed, and daubed the dear old place like this. I loved every tree and shrub in it, and I've dreamed of them, and been looking for nests, and playing hide-and-seek among them, a thousand miles away, with nothing but salt water all around. Why, they have taken away the very fuchsia which I saw poor Mary" (his dead sister) "plant!"

And now I have only to repeat, before I speak of "Bedding Out" descriptively, that, while I denounce the system in its exclusive usurpation of the garden, I heartily admire it as an auxiliary grace and gain; nor would I restrict its application to the grand terraces and the extensive grounds, of which I have before spoken. If I may suggest to you a rule for our guidance, it is this—wherever there is a goodly supply of the best hardy shrubs and plants, and space to spare, there let us have the bedding-out system, providing always that this space shall be occupied not only in summer but in spring. No part of a flower garden should consist of brown earth during those eight months of the year in which our climate permits, and we gardeners can provide, a covering of flower and leaf.

THE GARDEN.

[JUNE 22, 1872.]

GARDEN BEAUTY IN JUNE.

HARDY HERBACEOUS PERENNIALS.

To speak of garden beauty in June is to call up a vision of roses in the days of their own special month of high festival, the time when—

"The wings of the zephyr, oppressed with perfume,
Wax faint o'er the gardens of Gul in her bloom;"—

when our English flower-beds are as rich with the hues and perfumes of roses as that "land of the East" itself, of whose groves and flowers poets have sung in their most glowing words.

The present season, however, has not been favourable to the blooming of the earlier roses, and July will probably witness the true rose festival of the year 1872. Therefore, although the bloom of the Queen of Flowers is by no means absent even from this unfavourable June—that is to say the greater portion of its first half—it will, in their partial absence, be an act of floral justice to speak of those bevyes of lovely flowers which are so often completely overshadowed by the regal splendour of the rose at this period of early summer. Let us thus try for a moment to forget the superb beauty of the rose, and turn towards some of our hardy and beautiful herbaceous plants; and first to a group of homely, old-fashioned flowers, which are none the less attractive because they are homely and old-fashioned—I mean the Aquilegia family—the columbines—those light and graceful *figurantes* of the garden pantomime, whose gay presence is always welcome. White and pink, and crimson and purple, double and single, with their quaintly-beautiful forms poised, nodding and trembling, so lightly upon their slender stems, they are the true elfin beauties of the garden. Not only in the grand flower-borders of the mansion, but equally so in the little flower-decked patch beneath the cottage window, the old-fashioned columbine is an equal favourite. The monks of the old time, who lavished upon the margins of their holy books sweet pencilings of interwoven flowers, mingled with golden spangles, lovingly adopted the columbine as one of their favourite models, though they only seem to have known the common purple kind in their monastic gardens. Long cultivation has, however, produced in that pretty flora family an endless variety both of form and colour; and besides the original species, we have the grand *Aquilegia glandulosa*, from Persia, and the exquisitely beautiful *A. cærulea*, from the Rocky Mountains of North America; a magnificent specimen of which I have just seen at Tooting, growing as hardily and lavishly as the old garden kinds. To these should be added in every collection the noble scarlet-flowered *A. Skinneri* and the beautiful *A. canadensis*.

The Larkspur tribe (*Delphiniums*), too, are now in all their glory. Towering in massive spikes of many shades of azure and purple, they at once arrest the attention as veritable aristocrats among our hardy herbaceous plants. What can surpass the splendour of Barlowi, with the metallic purple of its double blossoms, except, perhaps, the rival charms of one of its own tribe, namely, the deep, dazzling azure of Formosa? And then there is the new grand variety, Mastodon, sent out only last year by the veteran florist Van Houtte, not to mention a galaxy of Larkspur beauty which I noticed among some promising beds of seedlings raised by Mr. Parker. Before dismissing the Larkspurs, let me not forget the distinct scarlet species (*D. nudicaule*) which has flowered throughout the month of May, and is yet in full beauty and still a very attractive object.

Now is the high summer of the Pyrethrums, which, as grand and perfect flowers, are quite recent results of careful hybridisation. This genus is decidedly one of the grandest recent additions to our ornamental herbaceous plants that are perfectly hardy. It challenges to floral combat the dahlia, the anemone, the Chinese aster, and, taking all its qualities into consideration, comes off an easy victor. The great variety of colour, the exquisite regularity of the more perfect flowers, and the graceful habit of growth and neatness of foliage, establish it in a very high place among the very choicest of our hardy herbaceous plants.

The Lilies, that is to say a very large section of the family, are in all their glory in June. From the stately white lily,

GARDEN DESIGN.

WATER MARGINS.

The introduction of water in an artificial landscape is one of the most difficult problems that beset the horticultural designer. Not only is it absolutely necessary to conceal the extent—which is generally very limited—but the character of the shore, and the judicious placing, and form of the masking island, are also most important, and extremely difficult features to manage fittingly. It is in these characteristics of an artificial lake or stream that the *ars celare artem* is most imperatively called for, and most difficult to achieve. The ugly brick-work round the canal in St. James's Park reduces the aspect of that otherwise fine piece of water to that of a farmyard duck-pond; and a similar name might be applied, with still greater force, to the lake in the Regent's Park, the shores of which, with the fine opportunities they afford of varied outline, might surely have been entrusted to an artist of a higher grade than the bricklayer; and yet such has not been the case, and consequently, the effect is precisely what a French critic would call that of the *basse-cour* puddle or pond.

What a contrast does the well-known Continental example

An Artificial Lake.

of an artificial lake, with which these remarks are illustrated, offer to the sad vulgarity of the treatment to which the Regent's Park water has been subjected! In the highly successful model engraved above, we have every variety of shore represented by skilfully-managed design. At one point it is precipitous and rocky; at another, the turf sweeps down gradually to the water and loses itself in an imperceptible outline; at another, low-growing shrubs that love the water's edge bathe their lower branches in the congenial element; and an island is so placed as effectually to conceal the extent, while at the same time it forms a most pleasing object in itself; a certain interest being secured to it by an architectural monument of graceful design.

The water in the Regent's Park would lend itself with singular advantage to a similar kind of treatment of its shores, if the authorities, who mete out garden beauty so very grudgingly to us, could be persuaded that the public would really appreciate something better than they are allowed to get, in the treatment of their parks and gardens. We have, close at hand, a successful example of what might be done, within the little circle of the Botanic Garden in the Regent's Park, where, by skillful devices, hill, and plain, and wood, and meadow, and water, are each made to play their parts pleasingly and effectively, within a restricted space. NOEL HUMPHREYS.

GARDEN DESTROYERS.

THE GOOSEBERRY CATERPILLAR.

The gooseberry grub or caterpillar deprives everyone of us of many a gooseberry tart and many a pot of gooseberry jam—a delicious delicacy, by the way, when made of little rough reds; this insect is a resident amongst us, and not to be scared away by any of our little manœuvres. Some years, however, are more favourable to its increase than others. Early one spring some years ago, or, to be more precise, about the middle of April, I saw the dies were already on the wing; very busy here and there, but in some localities only exhibiting themselves singly. These flies have certainly received half-a-dozen Latin names, but of these Ribis, or *Tenthredo Ribis*, is perhaps the best.

Having long been acquainted with the perfect insect, and being well aware of the probable result of its visitation, I kept my garden in a cloud of smoke—a practice at that early season not altogether grateful to the olfactories, but decidedly beneficial to the fruit crops. Thus I preserved my gooseberries and currants, while in many of my neighbours' gardens beyond the reach of the smoke nuisance the gooseberry bushes had to pass through the valley of the shadow of death; and as for the poor gooseberries, they shrivelled

into disgusting abortions after making a futile attempt to reddens into ripeness.

The parent fly of the caterpillar is a good-looking insect, and gardeners generally consider it a visitor with which they have little or nothing to do—"a species of thrip," to which some flea powder or beetle-killer might be administered with advantage if readily procurable; but, as the fly chiefly exhibits itself when skies are cloudless and suns bright, I have often heard it spoken of with some degree of approbation, evidently from its connection with smiling weather. I have often watched these flies glancing in the sunshine, chasing each other over the currant and gooseberry leaves, then in their youngest and tenderest state, spreading out their gauzy and glossy wings, the hind wings projecting from beneath the fore wings, like those of the lappet moth, and enjoying to the top of their bent the genial influence of the short but sweet mock summer with which we are generally favoured before the arrival of those biting eastern blasts which precede and usher in the real one, and which are supposed to bring the gooseberry grub into existence. I will now describe the fly, and, on the acknowledged axiom of *place aux dames*, I begin with the lady. The wings are four, perfectly transparent and almost colourless, but in the sun very often reflect prismatic tints like those of the rainbow. They have a number of brown rays, and a dark-brown semicircular sigmoidal spot about the middle of the costal margin; the antennæ are dark brown above, but beneath they are dull orange; the thorax is yellow above, with three shining black spots, the middle one of which is indistinctly

oval, the outer one on each side being somewhat crescent-shaped; beneath it is yellow, with two large shining black spots; the body and legs are yellow; the metathorax at the tip, and the whole of the metatarsi, are brown. The male has black antennæ, and the back of the thorax is wholly black. The three black marks, generally so distinctly separated in the female, are united in the male, forming a large blotch. I have been thus minute in my description, believing that some of my readers will like to make themselves thoroughly acquainted with the species.

The life of the gooseberry grub in its perfect or winged state is but another example of implicit obedience to nature's universal law "increase and multiply." Very shortly after the due celebration of the nuptials, the female repairs to the under-side of a leaf, and, after sawing a little slit on the midrib, deposits her first egg. Next, proceeding towards the tip, she deposits a second egg, then a third, and so on to the very tip of the leaf, or at least as near the tip as she can conveniently find standing room. The midrib being thus garnished, she next takes one of the side ribs, and then another, adorning them in the same manner, until all the principal ribs are garrisoned with her eggs, ranged in the prettiest rows. After the first day the eggs begin to grow, and before the end of a week they have attained three or four times their original size.

It is seldom that more than a week elapses between the laying and the hatching of each egg—between the moment of its being glued in the groove or slit provided by its parent, and its entrance into active life; but the period is not a constant one, since it varies from four to twelve days. The grub comes out head foremost. His body is nearly transparent, but just tinged with smoke-colour, the eyes—they are not real eyes, by the way, but ocelli—the eyes so conspicuous in the egg, still being very observable; but, as the head becomes darker, losing its pellicular character and acquiring colour, these gradually disappear. The grub seems to be born with a good appetite, for immediately on emerging from the egg-shell he crawls down from the ridge of the rib, and gnaws a little round hole in the softer part of the leaf. Immediately after making his first meal, the green of the leaf communicates its colour to the body of the caterpillar, which forthwith becomes green instead of smoke-coloured, but is still so transparent that the particles he has eaten show through the skin as a green line down the middle of the back, and it is this green line which tinges all the other parts. The little grubs descend from each rib in equal numbers, right and left, leaving the shells of the eggs attached to the rib, and looking exactly like so many little empty silver purses. The depredations are now visible from above, for a number of small round holes appear simultaneously on each side of each rib, ranged in irregular rows; in each of these holes one of the tiny glutinous may be seen clasping the edge of the hole between his legs, and elevating the end of his body in the air. At this nick of time, by a little care and industry you may save a good share of your gooseberries and currants. Each leaf has some sixty-seven little grubs feeding on it. In the course of a few days, if you leave it quite alone, the leaf will have vanished entirely—disappeared all but the stalk and two or three of the ribs—and the grubs will have separated and wandered away to other leaves. Each of them, after leaving this infant-schoolroom, would devour three whole leaves before it attained its full size; therefore, if that leaf were picked and destroyed with all its inhabitants, you save two hundred and one leaves.

When full-grown, the grub is, or ought to be, well known to every gardener; but perhaps some of your readers would like a description nevertheless. The legs, as in all insects, are six in number. These are longer than the legs of moth caterpillars, and not so hard and horny, nor so pointed at the ends. It has also fourteen claspers, counting the two with which the body terminates. The claspers are generally attached to the edge of the leaf while feeding, the first pair of legs being held free, and allowed to move with each movement of the head as he takes mouthful after mouthful. When full-grown the head of the grub is quite black, and the eyes are no longer to be distinguished; the colour of the body is dull bluish green, with rather paler sides, and a yellowish space just behind the head, and another just before the tail. It is distinctly divided into twelve segments, and each segment has a number of black warts; these warts, except on the second, third, fourth, and twelfth segments, are arranged in three indistinct transverse rows, and on each side of each segment is one larger and more conspicuous wart. From each wart rises a strong but short upright black bristle, and there are several of these bristles on the head itself. The spiracles are whitish, and the thirteenth segment has a shining black plate, ending in two short and rather hooked points; the legs are ringed with black and green, but not distinctly, and the claws are brownish; the ventral claspers are pale, semi-transparent green, and the cordal-claspers yellow.

When about half an inch in length, the grub leaves off eating: a very remarkable event, for its appetito is not intermittent like that

of most other created beings, but continuous—an incessant gnawing, craving, consuming propensity. The black head now separates from the neck, and splits down the middle, and the skin of the neck also splits, thus together making an opening large enough to allow the grub to poke out a new head which has been formed within the old one: a feat—that is, the poking out—which he forthwith performs, and gazes about him, moving his head slowly and majestically from side to side, as though he were just landed in a new world; and after the head comes the body, and after the skin is completely cast it has much the appearance of an empty stocking, and the newly-emerged grub has none of the black spots which previously distinguished it. The warts and hairs are certainly present, but the warts are colourless; the head is clear as glass, and the two black eyes so conspicuous in the egg and newly-hatched grub are again visible. In about twenty minutes the black spots begin to reappear, and in four hours become as distinct, and the head as black as before the moult. When the grub has regained its colour, it again begins to eat with a will, and eats away day and night for four or five days more without stopping. It then sickens again for its last moult, and this is performed in the same way as the previous one; but this time the spots, warts, and bristles are cast with the skin, and appear no more. The grub is now of a pale delicate green colour, except the yellow patch at each end, which it still retains. It has now done with eating. When hard enough and strong enough after this last moult, it marches to the main stem of the bush, and deliberately descends it until it reaches the ground, or more rarely crawls along a hanging branch, and allows itself to drop from the extremity.

The object of gaining the earth is to burrow beneath its surface, and no sooner does the grub once feel the soil than he forces his way into it head foremost, after the fashion of a mole. As soon as he is deep enough to answer his purpose—the depth varying, by the way, from two to eight inches, according to the hardness or stiffness or lightness of the soil—he makes a little oblong cell in the earth, and therein spins or constructs a tough blackish cocoon attached all round to the walls of the cell. In this cocoon he disposes himself to await the change to a chrysalis, and soon afterwards to a fly. The chrysalis is of a yellowish white colour, and each of the limbs, as well as the body, is clothed in a separate case or skin, which is cast off when the final change takes place. The fly is furnished with strong mandibles, the only use of which seems to be to gnaw a hole in the cocoon, through which to effect its escape.

The time occupied in this round of existence is very varied. Many of the eggs that are laid in May produce grubs before the middle of the month; these go through every change and are on the wing by Midsummer Day; and eggs laid about Midsummer will go through their changes as far as the cocoon by the middle of July. The first brood thus takes a calendar month for the round of its existence, and the second brood generally remains under ground until the following April, or perhaps in some instances even until May. It is, however, clearly impossible to lay down rules and dates for events which depend almost entirely on temperature and the varied character of soil and climate.

A word as to remedies. A favourite remedy for gooseberry grub is whitewash—the effect of which is deleterious to the leaves, and certainly prejudicial to the fruit. Strewing with quicklime has a similar effect. The free use of smoking weeds and the careful picking of perforated leaves I have already alluded to; I may add that some benefit will also result from treading the ground very hard about the roots of the bushes. An observant gardener will scarcely fail to notice that where bushes stand singly at the ends of patches of potatoes, peas, or beans, they are sure to be more infested by the grub than those in a close bed. The reason for this appears to be that the soil for all our culinaries is made as light as possible. In a bed filled with gooseberry bushes, on the contrary, there is but little moving of the earth going on, and it gets trodden hard when the gooseberries are ripening, and often remains so throughout the year. This hardening of the soil prevents the grubs from burrowing when they come down from the bushes full-fed; so they go wandering about, and become a prey to the redstart, hedge-sparrow, house-sparrow, whitethroat, and robin, as food for their young, and also to toads, which are always on the look-out at night for everything that crawls. This hardening of the soil also prevents so frail and feeble a creature as the perfect fly from forcing its way upwards through the superincumbent earth, so that those on the surface and those under the surface are alike assailed by this simple circumstance—contrivance I cannot call it. I have tried numberless experiments on the grubs themselves, and have found them very easy to kill: brine, tobacco water, snuff water, even plain water, hot or cold, are perfectly efficient; but all such remedies necessitate the capture of the grub before they can be administered with effect. Freshly-ground hellebore powder is said to be a good remedy.—*Edward Newman, in "Field."*

THE GARDEN IN THE HOUSE.

VARIEGATED AMERICAN ALOE.

It may seem almost superfluous to figure so well-known a plant as *Agave americana variegata*; but its use for decorative purposes can scarcely be too much dwelt upon. For halls, staircases, and lobbies, as well as for its more frequent positions on terraces and pillars and in conservatories, it is invaluable. There are, however, many places of this description where this species would be too large and out of harmony in its proportions with adjacent plants and other "fixings." For such places, there are many smaller species of *Agave*, which are just as easily grown, and quite as ornamental. I have no intention of attempting to describe these different varieties, since those who wish for information on this point can see a large collection of them at Kew Gardens, and can purchase plants from the leading London nurserymen, though not in any quantity. One of the best collections is that of Mr. Williams, of Upper Holloway; and in the second volume of his "Stove and Greenhouse Ornamental-leaved Plants" will be found full directions for

Variegated American Aloe.

cultivation, together with descriptions of seventy varieties of American Aloes (*Agave*). The African species, belonging to the genera *Aloe*, *Apicera*, *Gasteria*, *Haworthia*, &c., are all interesting and curious. Thanks to some few amateurs, and notably to Mr. Peacock, of Hammersmith, there has lately been more attention paid to this tribe of plants than formerly.

(Continued from p. 630.)

WATERING.

From various experiments which we have made in regard to watering plants in rooms during different months, we may deduce the following nearly correct rule for the guidance of the unskilled amateur: healthy evergreens, growing in moderately large pots and in light soil, and which have been brought from the plant-house into the heated room, should, in September and October, be well watered once about every three days, and from November to April once every two days. In summer, in hot, dry weather, and in an airy, open, and well-lighted position, they should be watered daily, if they are in a condition of luxuriant growth. On the other hand, healthy evergreens, in comparatively larger pots, and in stiff loamy soil, which have

been already growing in the room for some time, should, in September and October, be watered once every seven or ten days, and from November to April once every five or seven days. In summer, in dry, hot weather, and in a light, airy position, they should be watered once every two or three days. Ivy plants in boxes, as long as the ball is not filled with roots, should be watered only once a month.

TRANSPLANTING—SOIL—MANURE.

Plants grown in pots and other vessels, and also in glazed cases, receive only a proportionately small quantity of soil to furnish food for the annual formation of fresh leaves, shoots, and flowers. The smaller the pot, and the less the quantity of nutritious matter in the soil, the sooner will the latter be exhausted by the plant, and then, unless a fresh supply of nutrient be given, a scanty and feeble growth must be the consequence. The addition of fresh nutrient may be made either by renewing the soil in transplanting or by manuring. We shall, hereupon, consider the various kinds of soil, the time and manner of transplanting, and, lastly, the different kinds of manures.

THE VARIOUS KINDS OF SOIL AND OTHER MATERIALS USED IN TRANSPLANTING.

Plants are not all alike in their requirements with respect to soil, some needing one kind and some another; therefore, in all large gardens a mixture of different kinds of soil is prepared beforehand, or else soil is brought from field or forest, where it is found in a condition naturally suitable for the particular kind of plant. Composts and mixtures of various kinds may be obtained at most of the seed warehouses, but as the amateur may not always be able to procure them in this way, we shall describe the various natural earths and materials which may be used instead, and which may be found in most fields or woods.

SAND AND MOSS.

An important ingredient in every kind of soil is sand, which is so much the better adapted for plant culture in proportion as it is pure and free from other matters. The best is generally found on the banks of rivers. When it is mixed with clay or other matters it is cleansed in the following manner:—Fill a pail or tub about one-fourth with the sand, then pour in water and stir up well with a stick; by this means the clay, &c., becomes suspended in the water, while the sand sinks to the bottom; the dirty water is then poured off, and the operation repeated until the water appears perfectly clean. Sand may be used either by itself, as for cuttings and seeds, or mixed with the soil. It affords no nutriment to the plant, but only serves to make the soil looser and more open for the admission of air. Another material which is frequently used, and which, like sand, contributes nothing to the nourishment of the plant, is moss. The freer this is from earthy matters the better. Two kinds are employed, the green and the white. The first includes all kinds of a green colour which are found in woods and other localities, the best of which are the longer sorts of *Hypnum* and *Dicranum*, because they are more easily found free from earthy matter. The white bog-moss is more generally known by the name of sphagnum. It is found in marshes, where by its luxuriant growth it soon covers the holes made by the turf-cutters. The white colour of the dead under-leaves, and its thick, turf-like habit, render it easy to be recognised. It is commonly used for covering the drainage-layer of shreds in the bottom of the pots, to prevent the soil from being carried into the shreds by the water, and so choking the drainage. It is further employed in glazed cases and double windows in the culture of orchids, *Eschynanthus*, *Bromelias*, and ferns, sometimes to envelope the kinds grown on pieces of branches, and sometimes chopped up and mixed with the soil. Used in this way, it promotes the absorption of water, and produces an equable degree of moisture.

SOILS.

Among the natural soils, meadow loam, free from lime, is that which is most commonly used in the culture of plants which do not require special composts. The best kind of this is that which is composed of loam, sand, and humus (that is, decayed vegetable matter). The more abundantly humus in a partially decayed state is mixed with the soil, the more mellow

it becomes, and the better adapted for such plants as require a supply of nitrogenous and phosphoric food.

The sand and the undecayed humus render the soil loose, so that the atmosphere can easily penetrate it. From the humus is evolved carbonic acid gas; the alkalies of the loam partially convert the humus into humic acid, or pass directly into the plants, and, as bases of salts, play an important part in all vegetable growth. Lastly, nitrogen is supplied by the humus and the loam. This soil is consequently to ordinary plants a rich source of all these matters, which as food are conveyed by water to stem, leaf, flower, and fruit. The cases in which a greater or a less supply of nitrogenous or other elements is required are noted when speaking of the individual plants.

Such a soil is mostly found in dry fields which have long been used as meadows, and which have been enriched, from time to time, by a top-dressing of manure. When, as is often the case, the soil is mixed with the red oxide of iron, this is rather advantageous than otherwise.

When it is required at once for the culture of plants in pots, the sod should be thinly pared off, and the underlying soil, to the depth of not more than three-quarters of a foot, filled with undecayed roots, taken up. Deeper than this it is seldom in a suitable state to be employed in the culture of plants, as it either, where iron exists in the ground, contains the injurious dark blue oxide, or else is not rich enough in humus. When there is a facility for storing it, it should be spread out to a depth of six inches, the sods placed over it, and so left for some time exposed to the influence of wind and weather, which will greatly improve its quality.

If the soil be too stiff, it should be mixed with humus and sand, and when it is too rich in humus, which may be easily known by its dark colour, a mixture of wood-ashes or loam which has been made friable by frost, will supply it with the necessary alkalis.

Garden soil, which is formed by the mixture, during many years, of the original soil with decayed vegetable matter and manure, should only be employed in room culture when the original soil has been a loam, and has not received too much manure. Soil taken from a kitchen garden usually contains too much nitrogen for the greater number of pot plants, and, if used, should be mixed with loam and humus.

There are, indeed, many room plants which, under the influence of strong nitrogenous food, exhibit a much more luxuriant growth and a greater abundance of bloom. But it is recommended not to give these a soil too richly manured, as it readily becomes sour, and renders the culture of the plants more difficult during the period of rest. Liquid manure, of which we shall speak further on, is to be preferred to solid manure.—*Dr. Regel.*

(To be continued.)

IVY IN THE HOUSE.

WE do not sufficiently appreciate the Ivy as an indoor ornament, perhaps because it is so common with us out of doors. The following by an American lady, "Daisy Eyebright," shows what it is capable of as an indoor ornament:—

There is no other plant that produces so pleasing an effect as a luxuriant English or Irish ivy trained over the walls of a living room, framing a door or a window; draped about brackets, statuettes, or pictures. It is the most graceful setting that can be procured, and adorns the most common surroundings, rendering a plain room lovely and attractive. Placed in a hall, it will beautify and ornament it wonderfully. Trained in festoons over a stiff, straight window frame, it changes its appearance like magic.

There is no plant which strikes root more readily, and large trailing ivies nine feet or ten feet long can be purchased in any of our nurseries. For a room, place the stems in small bottles of water and hang the vials behind a picture frame, wreathing the leaves and branches about it. A rustic frame is best adapted to this adornment, as the stems can be more readily attached to it; yet a gilt frame looks very pretty when encircled with bright glossy foliage. If the picture is large, a pot can be made of zinc, and shaped like a wedge, of such dimensions as will readily fit between the wall and the frame, and it can be caught or fastened so as to be quite concealed, while the Ivy can be gracefully trained over the frame; but one must be sure to keep it filled with water, and put two or three bits of charcoal into it to keep it sweet, while a drop of aqua

ammonia added once a week will increase the growth. If the space between the wall and picture is large enough to admit of a wedge-shaped pan of eight inches in length, and three inches or four inches at the top, it can be filled with rich soil, and the plants will grow and flourish, although no sunshine reaches the roots, and send out long tendrils that will twine lovingly about the frame. There are many ways of growing the ivy; large branches can be put into glass vases, which must have bits of charcoal and a little stimulant of aqua ammonia weekly, and they will strike tiny white roots away down into the water, and throw out delicate green leaves from the upper branches, which can be trained around the mirror, over the mantel-piece, or twined around statuettes placed upon brackets on the wall.

For hanging baskets ivy can be made very available; by filling the basket with moss, and placing five or six small bottles of water among it, with a branch of ivy in each bottle with water, charcoal, &c., a very handsome appearance can be obtained; and if pressed fern leaves, mingled with bright-hued autumn leaves, are interspersed between the ivy branches, which can be made to twine upon the chains or cords which suspend the basket, the effect is really lovely. Each evergreen, heart-shaped, bright, glossy leaf, with its rich veining and shading, becomes a beauty, and well deserves the care it will demand at your hands; for if the basket is deep, you need fill up the small bottles or vials but once a week, but be sure to use warmish water when it is given. Such a basket is easily prepared, and will be a decided ornament to every room. Ivies do not thrive well in strong, bright sunlight; they prefer a shady place—in fact, they rather shun "the garish eye of day." They will grow finely in the farthest corner from the windows. A large pot can be placed on a stand far from the window, and it will twine its flexible branches all about the wall and cornice. The stems and branches can be fastened to the wall paper and the cornices of the room by small pieces of green worsted braid, tacked around them with silvered tacks. These can be easily removed, when it is desired to transfer the ivy to the verandah or porch, in the summer, or when the semi-annual house-cleaning demands its removal.

Ivies will endure any amount of neglect and still live; yet they repay the careful cultivator by a much more rapid and vigorous growth. The soil should be prepared with reference to the growth of wood and leaf, yet not too rich, as long, lanky stems, with leaves few and far between, do not accord with our standard of beauty. A good soil is composed of one-half good loam from a garden, and one-half leaf-mould and sweepings mixed. For growing in pots, set the plants into large porous clay pots, rather than ornamental pots that are glazed, as they do not admit of evaporation from the sides, and are not as healthful for any plants, though ivies will grow better in them than either roses or geraniums.

Ivies do not like a warm, close atmosphere; they will flourish best if kept in a cool hall or upper chamber. Indeed they will bear a chilly air without injury; and even if the soil slightly freezes, they will not complain by one drooping leaf. They also like much moisture, will bear wet feet better than most plants, and also require stimulants to induce them to grow finely. Plants raised from cuttings do not make much headway until they are two years old; then they commence to shoot forth new branches, and continue to do so every year. Their life is of long duration. No one knows how old are the ivies that adorn the ruins of England's ancient castles; hundreds and hundreds of years have passed since they began to creep "o'er ruins old." The ivy will strike root from every joint, and is easily propagated by layers from an out-of-door plant, as well as from cuttings.

Nemophilas for Cutting.—The merits of these for cutting are too little known; but they are excellent in winter and in fair light a room, their flowers being very beautiful for several weeks. Few would expect this, considering their transient nature in the flower garden.—*B. BRANDON.*

Early Irish Flower Shows.—Though horticultural shows properly belong to the present century, Dublin can boast of the existence of "The Florists' Club" as early as the reign of George I. It is to the Huguenots, as a body, some of whom settled in this city after the Revocation of the Edict of Nantes, that we must ascribe the general introduction and cultivation of flowers, and it was some of their members also who founded the flower club alluded to. They held their meetings in Dorset Street—then Drumcondra Lane—at an inn called "The Rose Tavern." This tavern must not be confounded with another of the same name which stood opposite to the Castle steps, alluded to by Swift in his old verses on his own death. Of this "Rose Tavern" Swift writes in 1731:—

"Suppose me dead, and then suppose
A club assembled at the *Rose*."

The Huguenots' Florists' Club that existed in Drumcondra Lane continued till the close of the reign of George II. Premiums were adjudged to the members who produced the most beautiful specimens of flowers, and certain days were set apart for the shows and meetings.—*Dubliniensis, in "Irish Builder."*

THE GARDENS OF ENGLAND.

TRENTHAM.

THERE are at least four elements of beauty and grandeur at Trentham—the house, the garden proper, the lake, and the distant woods and shrubberies. The house is massive, highly finished, lofty, and admirably fitted into its surroundings. So much so, that a landscape artist looking on Trentham for the first time would have some difficulty in determining whether the mansion was raised as a finished back to the garden, or the garden added as a basement for the house. The first garden in order of distance from the mansion is, therefore, highly formal and architectural. Each bed has its counterpart, on the same principle as the windows on the two sides of a regular house are alike. The furnishing of similar beds are also balanced as to style, height, and colouring, the latter

plants of *Humea elegans*, and pretty standard *Heliotropes*. A great difficulty is often experienced in merging the foreground into the middle distance, and this again into the background of landscapes. This is obviated at Trentham by boldly cutting off the colour garden from the next by a noble terrace walk and sundry architectural embellishments. From the colour garden we descend to another on a lower level, that might be called the grass garden. The velvet turf dominates here, as the mansion and the mosaic of flowers rule the first. The grass is broken and lightened up at regular intervals of great distances by large masses, mostly of cooler colours, the form, size, and furnishing of the beds being in striking contrast to those in the first garden. Thus we proceed from one style into another until, at the extremity of the garden, the eye is relieved by the lake, or rests itself with delight on the grand masses of foliage that engirdle its sides and drop themselves down into its

View of Italian Garden Front at Trentham, with Terrace, Pavilion, &c.

either contrasting or agreeing, so as to produce harmony. A good deal of colour is also used, *Pelargoniums* being the favourite plants for providing it, as they go through the season without flinching. In many modern gardens green leaves are displacing bright flowers; form is looked upon as of more importance than colour, and rightly so. But in such gardens as Trentham, with a heavy architectural pile behind, and the cool shadow of the large lake and far-reaching woods and shrubberies in front, colour is not only allowable, but essential. It lightens up the whole scene with a gleam of brightness. The colour is also placed where it ought to be—nearest to the house. The latter, in fact, stands behind a rich mosaic of flowers, bounded with broad bands of gravel, both giving a warm foreground to a scene of rare beauty. Lest, however, the colour should be too brilliant, patches of green and of cool tints are thrown in with admirable effect by the use of some of the smaller foliage and succulent plants, fine placid waters. We were not fortunate enough to find the lake

full. It was meant originally to be replenished from the Trent; but of late years that river has become far too foul to be used for that purpose. The water had also been lowered to facilitate the keeping of its bottom clean. When full it must indeed be a noble sheet of water. The wood on the right-hand side is truly magnificent. Crowning a bold promontory, and stretching along the whole side of the lake, there seems no end, neither in length nor breadth, to the rich mass of fine foliage. There is green enough here to tone down the flower gardens, were they all colour. It is this failing to grasp all the features of a landscape that has led to some of our greatest mistakes in the furnishing of gardens. We try to crowd all our shades, as well as lights, into the foreground; but the background should never be lost sight of. Its character ought chiefly to determine the colouring of the foreground. This seems to have been the case here. Nor is there wood alone at Trentham. On the left, the richest masses of shrubs skirt the

Trent, which meanders along between and among them, as if ashamed to show its black, slimy face, as well it might, amid so much sweetness and beauty. This rich clothing, while beautiful in itself, shuts out the site of the noble kitchen garden and fine ranges of glass, from the flower garden. These shrubberies, thick and massive at all seasons, are now lighted up with the glory of thousands of rhododendrons, azaleas, and other blossoms, which give an amazing richness to the scenery; and nearly all the prominent corners and telling points have quite recently been replenished with superior and newer varieties, and as these fill the eye first, the character of the entire group is remodelled and elevated by the skilful disposition of higher types of beauty. First impressions are not only the most pleasing, but the most lasting, and hence the importance of thus skirting common masses of shrubs and trees with those of higher excellence. You cannot but see them, and they assist very much to bring up the whole mass to their own high level. Hereafter we shall have something to say in reference to other matters at Trentham—of Mr. Stevens's miles of glass walls and houses crowded with fruits and plants of superior merit; but for the present we must be content to note those broad features of wood and water, and colour and architecture, that give to Trentham a grandeur almost unique, and a magnificence as rare as it is satisfying.

(To be continued.)

THE FRUIT GARDEN.

RUST ON GRAPES.

I HAVE never found sulphur sufficiently vapourised by the solar rays to inflict injury upon either grapes, or tender flowers, or foliage. Even on hot-water pipes, unless pushed to almost boiling point, sulphur is mostly harmless. Still, I do not advocate its use in vineeries with the fruit in a young state; whilst on vines sulphur is always dangerous just in proportion to the degree of heat employed, and the consequent extent to which the sulphur is vapourised.

I have had painful experience that the vapour of sulphur is injurious to delicate membranes, having frequently had my eyes affected, and once seriously for more than a week, by thinning grapes in an atmosphere strongly charged with sulphur fumes. Reasoning from analogy, I should say that the vapour that was powerful enough to affect most painfully the skin of my eyeballs, was strong enough to rust that of grapes. And it did; for in this very case the grapes were badly rusted. I also agree with those who say that rubbing, or mechanical abrasion of any kind, will cause rust. Hard water will likewise produce rust, or something closely akin to it, in this way—by leaving a deposit on the berries which sticks so closely that it cannot be removed, and by bringing substances into contact with them that penetrate their delicate skins. There are likewise several other causes of rust on grapes. One of the most prevalent is the practice of steaming vineeries at work when the berries are in a young and tender state. Flues, and very hot pipes, are deluged with water, and clouds of hot steam fill the house. These are often too hot for the delicate skins of the grapes, and rust ensues. The whole practice of damping down, and even of syringing vineeries, is undergoing a change in favour of more moderate and natural means of charging the air with moisture.

Again, another cause of rust on grapes is sudden draughts, and especially through draughts. So well is this understood by grape-growers, that many prohibit front ventilation altogether until the grapes begin to colour. The grapes swell more kindly and run fewer sins in the absence of a through draught. Nothing can hardly prove a more fruitful cause of rust than a current of cold air sweeping over the delicate skins of grapes. Another cause is allowing the sun to condense the moisture on the fruit before air is given in the morning, and then suddenly giving air enough to sweep the vapour off, thus subjecting the berries to a tremendous change of condition within a few minutes, and chilling them through to the heart and well-nigh freezing their skins at the same moment. Is it any wonder that the latter become ruffled by such treatment?

Finally, any sudden and unnatural arrestment of growth, either at top or bottom, will frequently produce rust on grapes, on the almost universal law that deformities of all kinds are mostly the products of "stunts," and that arrested development is the most fruitful parent of malformation and disease.

D. T. FISH.

—Apropos of the Rev. Mr. Reynolds Hole's remarks on this subject, I beg to say that my experience leads me to believe that cold and sudden currents of air between the flowering and stoning

periods are more frequently the cause of rust than sulphur. Certain I am that the latter will cause it if the pipes are overheated; but I am still more certain that sulphur often gets the blame when our own carelessness in the giving of air is at fault. I am sorry to say that I have at this moment, on some half-dozen bushes in an early viney, proof positive of it; but to give air and avoid draughts in such a season as this has been is enough to puzzle the best man among us.—W. WILDSMITH, *Winchfield, Hants.*

—Our first house of grapes is just beginning to colour; the bunches are large and heavy, but the berries are affected with rust. Of this, sulphur is not the cause, for we never paint our pipes with it, nor employ it in any shape. Rust on grapes may arise from many causes, such as syringing with hard water, or maintaining too close a temperature, especially where vineeries are heated by means of flued furnaces; doubtless, too, an excessive use of sulphur may cause it; but I am of opinion that in my case the grapes were handled too roughly when thinned, and that they were also rubbed with the head during that operation.—EDWARD JACKSON.

THINNING HARDY FRUITS.

The thinning of out-of-door fruits is one of the most important operations within the entire range of horticulture. Yet, strange to say, it is often wholly neglected, and mostly performed in a hap-hazard, rough-and-ready way. The thinning of grapes under glass, in bunch and berry, receives due attention, and is often carried to a perfection approaching to mathematical precision; but out-of-door fruits are seldom thought of; leave plenty on, and let the strength of the tree and the character of the weather regulate between them the final crop. We'll warrant these two to thin enough off in ordinary seasons, and an extraordinary crop now and then will prove useful. Yes, but suppose the weather and the tree thin too much, what then? You cannot replace the fruit when once it has been shot off in showers, and such wholesale deprivation is often the penalty exacted for the neglect of thinning. When fruit drops, the mishap is generally laid to the weather; but a dropped crop or a wretched harvest of worthless, small, ill-flavoured fruit is but the legitimate results of allowing the weather and the trees to do the thinning between them.

By leaving an excess of fruit, the fountain of growing force is speedily dried up; the growth of all the fruit is arrested. Then great haste is made to thin; but it is too late. Late thinning is just like locking up the stable after the steed has been stolen. We want to recoup the growing force, and send it all into the fruit left. To effect this early thinning is indispensable. Thin early, and the fruit kept acquires the portion of the fruit removed. Thin late, and that goodly portion is lost. In any case the strength expended upon the fruit removed is wasted. By grasping at too much we also frequently lose all. Leave a thousand fruit on a tree that has only vital force enough to finish two hundred, and note the result; you will not gather two hundred, but more probably none. The tree will take the matter into its own hand. Finding you mercilessly avaricious, it will revenge itself. Three courses at least are open to it, and it adopts either that seemeth to it best. Either it will shoot off the whole of its fruit, or it will retain all, and furnish a wretched harvest of deformed Lilliputs; or it will develop all to tolerable perfection, and sacrifice its health, future fertility, or life in consequence.

The mode of thinning is simple enough. "Progressive" expresscs it in one word—a little at a time; and a good many times, say six in all, are needed to complete the process. At the first thinning remove all deformed, ill-placed fruit, and reduce the nestling clusters to units. At all other times remove the smallest and weakest. With stone fruits, such as peaches, nectarines, and apricots, defer the final thinning until the fruits are stoned. When a knife refuses to pass through the stones, the danger of the fruit dropping is past. Up to that time a double crop may have been left on the trees to guard against accident; for some trees shoot off a good many fruits as they are hardening their stones. An excessive crop is one great cause of this tendency; still, on some soils and situations, it happens under the best management, and it is safe practice to hold a reserve till this last season of danger from self-thinning is past. As soon as it is over complete the process; go about it with a bold heart and a skilful hand, and err, if at all, on the side of thinness. Apples and pears may receive their final thinning when they have reached a fifth of their final size. By this time all deformed, ill-favoured, maggot-infested fruit will be revealed. Having removed all such, and all under-sized, badly-placed fruit, then proceed to reduce the sound and good to reasonable and proper dimensions. No fruit trees suffer more from want of thinning than these. Alternate crops, cankers,

blight, and other frailties and diseases, are but the language of reproach for barbarous over-cropping.

The extent of fruit thinning opens up a large and difficult question. It divides itself into two parts—the fruits that ought to be thinned, and the extent to which the thinning should be carried. Where the highest quality is an object, and labour is plentiful, I would thin every fruit, from strawberries to grapes inclusive. One large fruit is always better than three small ones; it contains more eatable matter, and generally of higher and better quality. This one will have less rind, seed, or stone than the three; and for appearance, who would not rather have the one large fruit than the three lesser ones? But the question of extent may be answered in another way. How far apart would you leave peaches, nectarines, pears, and apples? As a general rule not more than ten inches, nor less than four. But it might be desirable at times to allow the fruits to touch each other, and at others to widen the interval between them to twelve, or say eighteen, inches. On young strong trees or cordons the fruit can hardly be too close together. On weak-growing trees, whether old or young, the fewer fruits you take the better. Constitution, root room, food, future intentions regarding the trees, whether designed for a permanency or merely grown for the current crop, all such considerations must influence the extent of thinning, and the weight of crop taken from the trees.

S.

DISABLED PEACH AND NECTARINE TREES.

THERE is a point which I shall be much obliged to some one of your practical gardening friends to elucidate for me. The fact is simply this. Like most of my neighbours, my wall trees have suffered dreadfully from a combination of "curl" and late frosts, and are at this moment in a most miserable plight. My peach and nectarine trees have only been planted two years, and last year they made wonderfully good wood, so that I was in hopes of training them into beautiful trees. My wall is properly coped, and I take particular pains in protecting with scrim canvas. However, about six weeks ago, although "under canvas," the leaves began to curl to a very great extent. My gardener syringed, and syringed again, with various compositions and with water. In spite of this, some of the trees have died off; and although a few of them are making their midsummer shoots, I doubt whether they will not take another season or two to recover their strength; and I also presume that these midsummer shoots will be of no good, as regards fruiting for next year. Some gardeners have suggested to me that it was the frosts of six weeks ago which did all the mischief. Now the question I most especially wish to have answered is this:—Can a peach or nectarine tree on a south wall be likely to be killed or disabled by a spring frost? I confess my own idea had always been, that (if not properly protected at the critical moment) the blossom was likely not to set and to be injured. But I never imagined that the tree itself was likely to be destroyed by spring frosts. All the young fruiting wood on my trees has been completely destroyed, the young leaves being quite covered with aphides on the inside. This is, I presume, the cause of the curl in the leaf.

Sevenoaks.

W. B. N.

I SHOULD be glad if some one could enlighten me as to the nature of some blight that has come on most of my Peach trees this season. The blossom was good, and not much injured by the late frosts and snow in April; but soon after came blight, which entirely destroyed the foliage. The trees are as bare as they would be in winter, and the branches—small and great—are studded with reddish-brown seeds, shaped like cockle-shells, and filled with a white powder adhering firmly to the bark. I am having the trees loosened from the wires, the branches thoroughly cleaned, washed with a solution of Gishurst Compound, and the walls whitewashed. I have observed the same on some Golden Elms; but Nectarines and Apricots, although growing close to the Peaches, are quite free from the evil.—K.

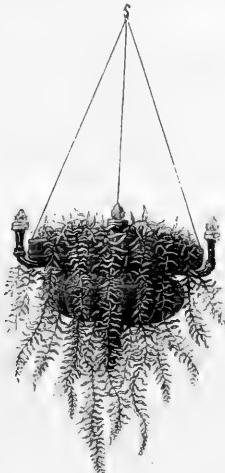

English Walnuts in California.—In the southern parts of California English walnuts are being planted, and the climate appears to be well suited to them. The first trees were planted in Los Angeles county in 1857, and commenced bearing in 1860. In 1863 nearly 10,000 pounds of walnuts were gathered, while, previous to that year upwards of 30,000 pounds were annually imported into that State alone. The flavour of the walnuts grown in California is said to be much finer than that of the imported nuts.

Cherry Grafted on the Laurel.—I have in my garden in Hampshire a cherry tree that must have been worked on a laurel some years ago; it has flowered and fruited freely for the last year or two; but not until last summer was I able to save any of the fruit, as the birds were always before me. I then, however, picked one thoroughly ripe; it was a black heart, well grown, and of excellent flavour; but the stone was soft, something like the stone of the laurel berry.

THE INDOOR GARDEN.

FERNS FOR BASKETS.

THERE are some kinds of Ferns that look better when grown in a hanging basket than in any other way. This especially applies to those which have creeping rhizomes, like the Davallias, or Hare's-foot ferns. The accompanying illustration does not do justice to probably the finest of all basket-forms, *Goniophlebium subauriculatum*; its elegant fronds, in full-grown specimens, may often be seen hanging down five or six feet long. Amongst the Maidenhair ferns are several that show off to great advantage in a basket, especially *Adiantum caudatum*, *A. assimile*, and *A. Farleyense*. The best kinds of Davallias for baskets are *bullata*, *dissecta*, and *pentaphylla*. *Nephrolepis exaltata* and *pectinata* both look well when suspended, but are not so good for a basket as *N. tuberosa*. *Platyloma flexuosa*, *Doodia lunulata*, *Asplenium flabellum*, *Pteris scaberula*, and all the species of *Drynaria* and *Nephrolepis* are excellent basket-ferns; and, although I have

Goniophlebium subauriculatum in Suspended Basket

never seen them so treated, I fancy that *Gleichenia Speluncæ*, and *hectostylus* could not fail to make fine specimens, when grown in a basket and allowed to hang over the sides in the tangled manner which they naturally assume.

W. T.

THE TREE CARNATION.

It has often surprised me that this beautiful and gratefully-scented plant is not more grown than it is. But even where it is grown its culture is frequently in such a backward condition, and the specimens so poor, that they give no idea of the beauty of the tree carnation. The first mistake made is that of layering the plants. Layering carnations is indeed one of the old customs worthy the "attention of the curious." They should be propagated from cuttings inserted any time from August to November, and in a propagating house or frame ranging in temperature from 55° to 60°, or on a gentle hot-bed under cloches or hand-lights. They will also do well if put in during winter or early spring as late as March. As soon as well rooted, pot the plants singly in small pots in sandy loam slightly enriched, and place them in a rather dry pit or frame with full exposure to the sun, or on the shelves of a cold house—in all cases near the glass.

In spring prepare a good border, bed, or quarter in a sunny position, enriched with some good loam, rotten dung, or cow-dung incorporated and intermixed, trenched, ridged, sweetened, and well pulverised by forked over in dry, frosty, and suitable weather.

In April the plants struck the previous autumn should be planted

out two feet or two feet six inches apart, for their summer growth, kept tied and staked, and cuttings taken off as previously recommended. If well done, these will be large plants by October, three feet or four feet high and through, and full of bloom buds.

When in the open air in summer they require no attention beyond cleaning the ground and staking the central shoot. It is better to pinch off the shoots and buds during summer till the end of August, when the central one may be allowed to rise.

October arrived, and the last batch of cuttings put in, take up the plants carefully with balls, and place them in pots, according to size, for a short time in a quiet, partially-shaded situation; stake and tie. Many will now be full of bloom buds, and some coming into bloom. Place them, as soon as they are a little settled in the pots, about the conservatories, greenhouses, or where you please, to flower all the winter. A few about Christmas can be placed in a little heat such as is employed at the first commencement of putting a viney, peach, or fig-house to work; two-year-old plants are the best for this early forcing. They should not be over-potted; it is better to feed the plants with well-diluted liquid manure. Seven or eight inch pots will usually suffice, but larger specimens may require larger pots. It is my rule to discard the old plants generally by turning them out in a border, where they yield flowers during the summer; thus, by a little management, one can have tree carnation blossoms at all seasons. In America, where such fine varieties as La Purité and Dégraw are grown by hundreds of thousands, the system here described is the one pursued. In the winter, the plants are placed in warm light houses, and the flowers are used in immense quantities for bouquet-making. In America, where they are thus grown in quantity, instead of potting the plants, they are often planted directly on benches, by which means as good or a better result is obtained than when they are grown in pots, and with less trouble. Q.

ANOTHER NEW HEATING MATERIAL.

TANNER's bark, tree leaves, and stable manure have hitherto been the stereotyped agents in use in gardens for supplying plants which require it with bottom-heat. The two first-named have the further advantage of affording an excellent and conveniently available medium for "plunging"—the technical term for inserting pines or other plants in pots in the heating material. When we say these were the only agents in use for supplying bottom-heat, we mean agents that produce heat by fermentation, or while undergoing the process of decomposition. Of course, the flue and the steam or hot-water pipe are available for the purpose; but these, however, are purely artificial agents. Unless in the neighbourhood of large towns, where there are tanneries, bark is not to be had. Unless in places of some extent, and pretty well wooded, tree leaves cannot be had in sufficient plenty, and in many places there is by no means a glut of stable manure for the wants of the garden.

We are glad, therefore, to direct attention to another heat-producing and useful plunging material that has recently come into use, and has been found practically in many respects superior to tan, &c. This material is the refuse or waste that accumulates during the process of dressing flax. It consists of the external coating of the stem, broken and triturated in the mill, mixed with a portion of waste fibre. Among its advantages over tan a very important one is that, where available, it comes dry from the mill, and ready for getting into the pit at once, while the former requires to undergo a drying process under cover, or at great risk in the open air, for some ten days or so before being used.

It does not appear, like tan, to be a favourite haunt for worms, which generally abound and are a great nuisance in tan pits. Neither does it seem to be so favourable to those soft fungoid growths sometimes so injurious, in their magically-rapid development, to plants plunged in tan. When spent, we should consider the flax refuse a much superior manurial agent to spent tan. When got into the pit the heat is as rapidly developed with the flax refuse as it is in tan, nay, perhaps more so, and is retained perhaps longer. We were speaking of it to an eminent pine-grower this week who has been using it, and his words were, that "for the purpose of pine-growing it is invaluable." He was equally impressed in favour of it as regards its use in melon or plant pits. In Ulster, where scutch mills abound, our gardening friends can have it very generally available. As we hope flax will, too, become a staple product of the other provinces, the day, we trust, is not distant when it will be equally available in the south as in the north. In fact, gardeners in the vicinity of Cork have already at their doors a source of supply in the magnificent flax mill recently erected just outside that city. We have heard of flax refuse being used about Dundee, and perhaps one or two other places in Scotland, but cannot vouch for

the fact. At all events, its use is little known here. It is only within the last year or so that it has been used about Dublin, and that only in one or two gardens in the vicinity of Chapelizod, where there is a large flax mill. Those who have used it are very favourably impressed with its utility. As regards the cost, we believe in the first instance it might be had for the removal; now that a demand has sprung up, a shilling or so a load is asked for it.—*Irish Farmers' Gazette.*

PUBLIC GARDENS.

THE NEW PARK AT BROOKLYN.

NOTWITHSTANDING the efforts of the rascals who combined to fleece the American people while filling important positions in the councils of their cities, there is no country where public gardens have been more nobly made. Not only are some of the American public gardens worthy to compare with any of ours, but in point of design they are far before them. Here is an example, which, if compared with the plans of any of our London parks, new or old, will be found to have very great merits indeed, and to show much thoughtful design. We had the pleasure of visiting this park in 1870, accompanied by Mr. Olmsted, of the firm of Olmsted, Vaux, & Co., of Broadway, New York, who designed it. We were much pleased with its wide lawns of green turf, its fine sheets of water, capital and extensive drives, the wide boulevards which converge towards its main entrance, and last but not least, the provision made for public meetings outside its gates. Surely, our clamour about meetings in the parks might be assuaged by providing a roomy place for public meetings, as the people of Brooklyn have done in this instance. By so doing we should save our flowers and shrubs and trees, and peacefully accommodate, if need be, a meeting of forty tub-orator power. The place of meeting is, as we have just observed, outside the main entrance of this noble park, where there is a raised stone platform for the speaker and sufficient room, and every convenience, for a vast crowd. In addition to the broader features of the park (which are sufficiently shown by the annexed illustration), the following interesting and somewhat novel features are worthy of record here:—

Besides the wide open lawns there are provided "places of congregation and rest," each adapted to the assemblage of large numbers of people. The first of these is designated the "Look-out." The circumstances which made a special arrangement for the accommodation of an assemblage at this point desirable were—first, a view is obtained here, and nowhere else in the park, of the outer harbour, the distant mountain ranges of New Jersey, and the ocean offing; second, the peculiar advantages which the elevation offers for the enjoyment in hot weather of the sea breeze; third, the interest of the local scenery; and, fourth, the bird's-eye view which will be presented of military evolutions, if the projected parade-ground should be formed south of the park.

From the "Look-out" broad walks lead across the park to the east end of the lake, where, at a point commanding the largest water view, together with a rich open meadow landscape, backed by the highest elevation of the park, pinnacled with evergreens, arrangements for open-air concerts are made. Within a distance of two hundred and twenty-five yards of an island, where musical bands are usually placed—at which distance the music of a well-appointed band can be perfectly appreciated—standing room is provided for horses and carriages in a circular space about five hundred feet in diameter, and in an oval space at a higher elevation, three hundred feet long and one hundred and seventy-five feet wide; while directly in front, at a distance varying from one hundred to five hundred feet, a space is provided, to be occupied by shaded seats, sufficient for over ten thousand people. The provision for a resting-place for vehicles is in consequence of the widely developed taste for driving which exists in every American city. It is this also that causes the formation of the admirable drives which are made near all the large cities and in the large parks.

Round the lawns, the meadows, and the slopes of the upper lake, is a display of the finest American forest trees, standing singly and in open groups, so as to admit of the amplest

the effect of which can never be overrated, to the deep crimson and scarlets of new varieties of that section of the family to which the old favourite "orange lily" belongs (say *Lilium fulgens Sappho*, for instance), there is a wonderful variety of beauty to select from, especially when the Martagonas are included, among which none surpass the grand old "Scarlet Turk's Cap." What a June garden might be contrived of lilies only!

The Dianthus tribe—our pretty pinks, and their congeners the Lychnises and Silenes, are now putting forth all their floral power. In the Lychnis family, what can be more attractive than the double varieties of *L. Viscaria*, from pale pinky lilac to deep crimson? and what new plant, however beautiful, can surpass the splendour of the grand old garden favourite, *L. chalcedonica*?—it was one of the garden glories of the olden time; its heads of flower form a mass of brilliant scarlet, which, when the sun is shining upon it, is too dazzling for the eye to rest upon. Of the distinct species and garden varieties of pinks, what shall I say, except that they are all charming, and that the Sweet William division forms as grand masses of rich colour as any flowers in cultivation?

The grand Oriental Poppy now forms gorgeous patches of black and scarlet, and well replaces the peonies, which are on the wane. Other members of the Papaver family are nearly as conspicuous; as *Papaver pilosa*, for instance, with flowers of orange-vermilion, and *P. lateritia*, with smaller flowers of similar hue. To these might be added several others of the family, not forgetting the pretty yellow one popularly known as the Welsh Poppy.

The later Irises of many kinds must be classed as among the most elegant of the floral beauties that grace the June garden with their presence—some of which are, indeed, strikingly beautiful. The division of the tribe commonly known as the Spanish Iris, with its crisply-formed flowers, quaint in form as Gothic carvings, is now just entering upon its flowering season, and will last for some time after the glories of the true broad-petaled kinds of the more graceful flower-de-luce, or fleur-de-lis, have passed away for the year. Though not nearly so elegant in form, the quaint, and at the same time dazzlingly rich mixture of colouring of the hundred varieties of Spanish Iris, render it a charming feature in a June garden.

The Allium family, notwithstanding that they are "garlics," must, from their beauty and variety, be perfume admitted, as bright-hued and attractive flowers in our June garden. The brilliant masses of profuse bloom of pure canary yellow, which *Allium Moly* puts forth so lavishly, should have a conspicuous place in every border, where they may be left to do duty, and not be gathered for the bouquet, as their somewhat too high-flavoured odour is not intended for close appreciation. The beautiful blue-flowered *A. azureum* is an extremely pretty plant; its subdued azure being of a very peculiar tone, and I noticed half a score other species in flower in that portion of the Botanic Garden at Kew devoted to the genus, several of which are well worthy of cultivation as attractive garden flowers.

The Campanulas, their colour being chiefly confined to tones of blue, with white varieties, are most of them in all their pride of bloom in June, and many of them are extremely handsome. Conspicuous among the taller kinds may be named the fine old peach-leaved kind, known as *C. persicifolia* and the clustered one *C. glomerata*, and the broad-leaved harebell *C. latifolia* and its large flowered variety, while among the dwarf ones are such gems as *C. pulchra* (which is flowering freer in the open border than I ever remember to have seen it), *C. fragilis*, and *C. gorganica*. *C. punctata*, which forms a deep cream coloured bell, is very remarkable, and there are many fine species which ought to be in cultivation and are not.

The Lupines and their near relatives the Baptisiae are nearly all June flowers. That noble herbaceous perennial, *Lupinus polyphyllus*, is none the less superb for being common in every garden, for it forms such compact masses of purple spikes of flower as no other plant, not even the Larkspur, gives the gardener the opportunity of producing. *L. arboreus*, a shrubby kind with yellow flowers, should be in every garden, while the *Baptisiae*, *australis*, and *alba*—blue and white, or *Thermopsis fabacea*, yellow—should never be absent where an

effect produced by varieties of the Lupine and its congeners is intended.

The Pea tribe from the Tangier to the common everlasting pea afford us many effective plants; and there are scores of other fine things scattered through a great variety of genera, some found in one garden some in another, but never met with collected in a single garden, however profuse in its aggregation of floral riches; and for a very good reason, namely that no single garden could offer sufficient space for a fitting display of all the flower-beauty that is in the full flush of blossom in this climate in the month of June.

I have confined myself, in the present instance, in describing my impressions of garden beauty in the present month, to the mere naming of a few of our best known hardy herbaceous plants, which, though well known, and indeed common, are in many instances much neglected, notwithstanding their beauty and the glorious effects which, when massively employed, they may be made to produce in our gardens.

In concluding I cannot help noticing the determined effort of Mr. Parker, of Tooting, to bring some of our grand herbaceous plants into greater prominence and estimation by means of pot culture. A pot of Iris, for instance, and one of Pyrethrum (among many others recently accepted), struck me as truly superb. The pot of Iris, with judges unaware of the relative rarity and value of plants, would most certainly have beaten any stove exotic, even had it been a Cattleya labiatissima.

On another occasion, should time and space permit during the busy floral month of June, I intend to notice the wonderful beauty of alpine plants in full flower on rockwork at this season; and also to say something concerning the fine flowering shrubs that have succeeded to the lavish blooming of the lilacs and laburnums of May.

NOEL HUMPHREYS.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE FORTHCOMING ANNIVERSARY DINNER.

This charity, like so many others, may be said to have three sources of regular income—subscriptions, donations, dinners. Besides these there are two others that are accidental—the special gifts once for all of the living and the legacies of the dead. Considering the objects which this charity has in view, it is not too much to add that the whole of its sources of revenue ought to be increased—doubled, trebled, or more. Few charities can have a stronger claim to public support; while it has special claims on the employers of gardeners, who are the wealthiest and the most generous class in the community. The charity is, moreover, wisely and carefully administered, while the objects of it are the unfortunate and the disabled, and not in any case the imprudent or the reckless. It can hardly be said of the recipients of this charity that they have had the opportunity of providing for themselves. The majority of gardeners spend nearly half their time at labourer's wages learning the mysteries of their ever-changing profession. It has been facetiously remarked that gardeners take out part of their income in kind—in the pleasures of their business, the beautiful sights and scenes that surround them, and exceptional healthfulness of their pursuits. To say nothing of the impossibility of feeding, clothing, and educating a family on the beauties of nature or the more polished productions of art, the list of applicants for pensions from the Gardeners' Benevolent Institution is a bitter parody on the extreme salubrity of gardening. The fact is, the sudden and extreme changes of temperature to which gardeners are exposed, lay them open to the attacks of rheumatism in all its hydra-headed cruelties of development. This disease is the natural enemy of gardeners—"pursuing them fast through every lane of life, nor missing once the track," until it strikes them down by hundreds, comparatively in their prime, premature wrecks of helplessness and suffering. The men's hearts are still in their business, their heads are as clear, their experience more valuable than ever, but their hands, their feet, their backs are set fast in worse than iron fetters. It is bad enough that such have to suffer, but the question is, Are they to be allowed to starve as well? or, are those who have adorned the higher walks of horticulture or

lighted its commoner paths with the light of a good and brave life and a pure character to be permitted to sink to what many of them dread more than lack of bread—the Union? and end their days, begun amid so much hope and beauty, on pauper's fare and on a pauper's hard, lonely, and friendless bed? No. Never; surely, while the horticulturists of Britain can prevent it. It is but little that the Gardeners' Benevolent Institution offers to its pensioners—£16 a year to men, and £12 a year to the widows of gardeners. Let us at least see to it that this little is forthcoming to all who need it. May the forthcoming be the last election at which we shall read of "second, third, and fourth applications." Did the funds permit, the committee would only be too happy to relieve every applicant that comes within the stringent rules, some of which seem designed rather to bar out than bring in the helpless and the suffering.

The Rev. Mr. Reynolds Hole is to take the chair at the dinner on Monday, the 2nd of July. Let that announcement be passed round as the summons to action among all true gardeners. We have had a gardener in the chair before—Sir Joseph Paxton; but he was more than a gardener, he was an architect, a statesman, and much more besides. Mr. Hole is a gardener from head to foot (six feet—we know not how many inches more—of horticulture), crowned with roses. He is likewise a worthy clergyman, a brilliant writer, and an admirable speaker; his prose being better than some people's poetry. Now, therefore, is the time to prove our fealty to our leader, by rallying to the support of the charity which he has been pleased to honour and serve by presiding at its anniversary dinner. If this charity is not all that it might be, it is, nevertheless, good as far as it goes, and does good work in ministering to the necessitous and distressed among us. Besides, it is the only one. We have no other means of helping our brothers and sisters in the time of need. No one knows better than Mr. Hole how many hearts will be with him whose faces will be unseen at the festive board. It is not many gardeners who can afford a guinea for a dinner and another for travelling expenses. And if they could, perhaps a donation to the charity would prove more serviceable. Most of us can do something, however little, to extend its usefulness: we can canvass for new subscribers, give an extra donation, bring its claims before employers, and make a special effort to secure life members.

NOTES OF THE WEEK.

— VISITORS to Birmingham who wish to see the gardens or country seats in the neighbourhood of that town, will find excellent aid in "The Birmingham Saturday Half-Holiday Guide."

— THE plan and view of the great temperate house at Kew which appeared in THE GARDEN last week were engraved for us from drawings kindly lent us by the architect, Mr. H. M. Burton.

— MESSRS. GRIMBLEY, HUGHES, & DEWE, of Oxford, closed their establishment to enable their employés to visit the flower show that lately took place in that town.

— M. BELHACHE reports, in the *Revue Horticole*, having found the fine *Saxifraga pyramidalis* growing freely on the thatch of a house in Normandy. It is one of the many plants we have pointed out as not only suitable for old walls, roofs, &c., but which thrive much better in such positions than in the garden proper.

— A NOVELTY in Bath, a flower sermon, is announced by the teachers of Percy Sunday Schools, as about to be preached by the Rev. R. P. Macmaster, of Bristol. Each young person attending this special service is requested to carry a bouquet or wear flowers, which request will no doubt be universally complied with.

— A FINE bush of the laurel-leaved *Cistus* (*C. laurifolius*) is now in flower in Messrs. Rollinson's nursery at Tooting. The plant is about three feet high, and is literally covered with large white flowers, many of which are nearly three inches across, causing it to appear at a distance to be a perfectly white bush. This distinct species is perfectly hardy at Tooting, plants of it having stood out for several winters uninjured, whereas plants of the common laurel planted near have often been killed. It is well worthy of a place in any shrubbery or on the rougher parts of rockwork, pleasure-ground banks, and similar places.

— MESSRS. SUTTON, we understand, will not withhold the special prize offered by them at Birmingham for the best collection of six sorts of peas in the event of its not including their new late pea "Best of All," which may not be ready in time owing to the backwardness of the season.

— A CORRESPONDENT of the *Country Gentleman* says he has preserved his garden stakes—made of pine—by boiling them for a short time in a solution of blue vitriol, and after long use they are as sound as the day they were made, while other stakes, coal-tarred, have failed.

— WE are informed that two fine specimens of the Hardy Palm (*Chamaerops excelsa*) are now flowering out of doors in the nurseries of Messrs. Backhouse & Son, York. Planted on a lawn facing the south, they have stood the test of several severe winters unprotected.

— THE Pyrenean Columbine (*Aquilegia pyrenaica*), a rare dwarf species, is now in flower at the Royal Horticultural Society's gardens at Chiswick. The plant there is scarcely six inches high, and its flowers are a deep purplish blue. It is worthy of a place in any collection of alpine plants.

— *SEEDUM NEVII*, a new and distinct North American species of stoncereop, is now in flower at the Hale Farm Nurseries, Totternham. The flowers are white, and are produced in somewhat the same manner as those of *S. pulchellum*.

— THE *Wine Trade Review's* Bordeaux correspondent writes, under date June 10th:—"Up to the present time the vines have not suffered much from the cold and rainy weather of the past month, none but the vineyards on heavy or low ground being affected. A period of warm sunshine is, however, now indispensable for the proper flowering of the vine."

— THE magnificent Rhododendron Falconeri is now in bloom in the temperate house at Kew. This, although rather a shy flowerer, appears to thrive admirably planted out in borders, along with others of its class, in this conservatory. Its blooms are of a creamy-white colour shaded with pink, and are larger than those of any other species of Rhododendron in cultivation.

— WE understand that the Marquis of Bute—from a desire to prevent modern roses from entirely supplanting the older sorts familiar to us in days gone by—has kindly offered for competition at the forthcoming West of England Rose Show two special prizes, viz., one of £3 for the best collection (twelve) of the oldest known and most attractive garden roses, and another of £2 for the best collection (twelve) of the York and Lancaster variety.

— MR. AVTON states that steps have been taken to obtain an adequate supply of fresh water for the bathing ponds in Victoria Park by means of boring, and that the necessary work will be completed within a short time. It would not be desirable to empty the lakes during the present warm weather; but when the proper season arrives they will be cleaned out.

— THE fine weather which we have experienced during these past few days has induced growers of sub-tropical plants to trust many of their treasures out of doors. Prominent amongst things put out may be named *Ficus*, *Cordylines*, green-leaved *Dracennas*, *Wigandias*, *Polytmias*, *Verbesinas*, *Senecio Petatasites*, *Cannas*, *Aralia papyrifera*, and some of the harder palms.

— THE Dowager Marchioness of Westminster lately invited the whole of the tenantry on her estates in Wilts and Dorset to a garden party at Fonthill Abbey, one of the most beautifully situated residences of her ladyship. A capital luncheon was served up in a marquee on the lawn in front of the old abbey tower—the only portion left standing of Beckford's princely mansion—for three hundred and fifty guests.

— THE London correspondent of a provincial journal tells us that never was the business of the horticulturist so flourishing as it is now. The demand for flowers is extraordinary, and the prices given for them amazing. Belgravian dinner-tables are now regular bowers of flowers and ferns. At a recent dinner in Harley Street (by no means one of the most fashionable streets in London), the flowers and dessert cost £200, the peaches alone being twelve guineas a dozen.

— THE excessive heat which has prevailed in London during the last few days has not been felt in all parts of the British Islands, as the returns to the Meteorological Department show. At two p.m. on the 18th, the shade temperature in London was 85°, while at some stations it was below 60°. The highest sun temperature noted on the 18th at the Royal Observatory, Greenwich, was 145°. A Yorkshire telegram says that a heavy thunderstorm broke over the Yorkshire Wolds on that day. A young gentleman was killed in a field near Mowthorpe; two women close by escaped. There was a perfect hurricane on the south side of the Wolds, and trees were uprooted.

In the south of Ireland the weather is still cold and wet, more like that of early April than June. The frost of the 22nd ultimo very much injured fruit crops. Scarcely any pears remain, either on walls or standards, except very early ones, such as Citron des Carmes, which have escaped. Fruit of gooseberries, which were frozen, have dropped off. Of strawberries, two-thirds are destroyed. Cherries set well, but got frozen, and are a poor crop. Apples, too, are indifferent. Altogether this is a bad fruit season. Potatoes have likewise suffered terribly in low-lying places; those in high, exposed situations are best; new potatoes will not be in for another week yet. Vegetable crops are greatly injured by slugs.

WE believe there is now flourishing in the grounds belonging to Sir John Taylor Coleridge, at Ottery St. Mary, a small plantation of trees transplanted from the Tichborne estates, and christened the Tichborne knoll, in commemoration of the great case. These trees were given to the Attorney-General for the purpose described, by the ladies of the Tichborne family, as the only expression of their appreciation of his services which he would receive. This incident proves that whatever the outside world may think as regards the Attorney-General's compensation, the family itself felt that no amount of money could adequately represent their sense of his successful devotion to their cause.—*Law Times*.

THE owners and leaseholders of land abutting on the Upper and Lower Malls at Hammersmith, where it is proposed to form an embankment on the foreshore of the river, extending from the pier of the Hammersmith Suspension Bridge to the Upper Mall, have intimated to the Fulham Vestry that they entirely concur in the proposed embankment. They say that in consideration of the great improvement likely to follow, they will be quite willing, without pledging themselves to any specific sum, to contribute a substantial and proportionate amount towards the cost of the embankment. All they stipulate for is, that any rights they may possess shall not be injuriously affected by the proposed works.

Babianas.—On Tuesday last Mr. Gumbleton brought us one of the most charming bouquets of early summer flowers we have ever seen. It consisted wholly of Babianas, a lovely race of plants, too much neglected in our gardens, although endowed with the richest and most delicate hues. Probably some difficulty in cultivating them makes them so rare in collections, but Mr. Gumbleton grows his with other hardy bulbs in his garden at Queenstown. He has kindly promised to say a few words on their culture some day in *THE GARDEN*. The following are the varieties brought to our office:—
 1. *Angustifolia*, good purple with brown spot at base of each petal.
 2. *Atrocyanea*, light lilac purple with faint spot.
 3. *Celia*, beautiful deep rose-shaded carmine.
 4. *General Scott*, white shaded lilac.
 5. *Kermesina*, good clear rose.
 6. *Rosea grandis*, fine deep purplish rose.
 7. *Pallida*, pretty clear lilac and white.
 8. *Speciosa*, large deep lilac faint-shaded white.
 9. *Lady Carey*, shaded white pink rose.
 10. *Villosa*, lilac and white.

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from p. 613.)

GROUP 3.—GRAFTING DE PRECISION.

GRAFTING *de precision*, or precise grafting, implies that the stock and scion are so accurately prepared and fitted to each other, that when they are put together they will coincide perfectly, without using any force, and without leaving any vacuum. The rigorous exactness which the operation demands, has led to the invention of special implements, such as the combined grafting-knife and the metro-greffe. Spring is the proper season for precise-grafting. It succeeds also in summer, if care is taken to select the woody part of young branches for scions, to shade them, and keep them from getting dried. Towards the end of summer, when the flow of the sap is diminishing, this method may also be employed, observing that the sap should be sufficiently active to produce immediate cohesion, but not so active as to cause an autumnal development of the buds. Experience accustoms one to perceive the moment when the sap begins to thicken, when the functions of the leaves are at an end. Under this new title of "precise-grafting," we class veneer-grafting and grafting by inlaying.

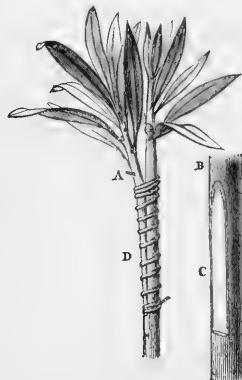

VENEER-GRAFTING.

GENERAL DIRECTIONS.—This method is principally employed in grafting a certain number of trees and evergreen shrubs, and for grafting under glass with the air excluded. Nurserymen and florists practise it in the open air or in the propagating house, in spring, rather than in autumn, especially in the case of evergreens. A stock with the sap in a condition of moderate activity and a well-ripened scion are the two first essentials. The scion may be a shoot of the current year or of the preceding one, according as the grafting takes place in the autumn or in the spring. Its length varies from two to six inches, and it must be cut with a flat splice-cut without the least unevenness, in order to fit the stock exactly. If it is evergreen, the leaves are not removed, and it is not cut from the parent-tree until immediately before it is fixed. The metro-greffe here comes into requisition; with its help a cut is made in the stock the exact size of the splice-cut on the scion. Nothing then will obstruct the union of wood and bark. The two parts are put together without cleft or insertion, by simply applying the scion to the top or the side of the stock, under the bark, or with the bark removed, employing either one scion or several. Such are the various modes of branch veneer-grafting. We shall proceed to treat of them in detail, without speaking of veneer bud-grafting, which is described in the chapter on bud-grafting, as we are now engaged with the subject of grafting with detached branches only.

ORDINARY VENEER GRAFTING.—By this method a scion is brought into contact with the first layer of alburnum in the stock. The stock is not to be headed down beforehand. In the case of an evergreen, the leaves on the part destined to receive the scion, are cut off at the stalk or in the middle; the scion also should not be cut from the parent-tree more than a day before it is used, and its leaves should not be removed. The scion having been cut with a straight, longitudinal section, its diameter is taken with the metro-greffe, which is then applied to the stock (B), and the dimensions of the section of the scion are traced with it.

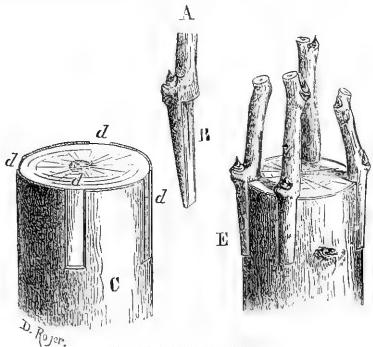

Nothing more remains to be done but to cut away the part between the two marks, to correspond exactly with the section of the scion, so that they may fit as at D. First remove the bark, and if that is not sufficient, cut the first layers of the alburnum (C). Instead of a metro-greffe, a grafting-knife or a common pruning-knife may be used. Place the scion against the stock, and with the point of the knife mark out the outline of the section, and then cut away the bark and woody layers. The scion is fitted to it from time to time until the parts are accurately adjusted. A bandage of either woollen or cotton thread, with close turns, is indispensable. Grafting wax is not always necessary. Instead of a flat section on the stock and the scion, notches or tongues may be cut, which will fit into each other. This is the English method.

VENEER CROWN-GRAFTING.—The scion is not cut with a sloping or splice cut. A notch at the top of the cut (B), such as is made in ordinary crown-grafting, will be useful to set the scion square on the stock (C). With the metro-greffe the diameter of the cut (B) is marked out at d, d, d, successively, where the scions are to be applied. As the double spatula has cutting edges, the bark will be divided; it is then removed, and the scions placed as shown at E. The application of the bandage and wax is indispensable. The bark only has been removed; the alburnum is not cut. A large tree is more easily grafted than a small one, because the latter presents a

Ordinary Veneer-grafting (*Rhododendron*).

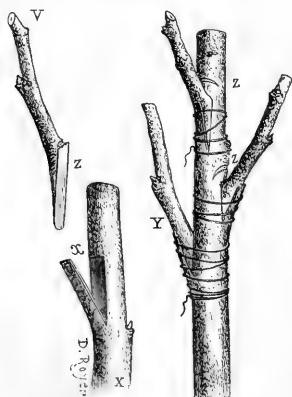

rather convex surface, and would necessitate the cutting of the alburnum in order to fit the scion in properly. With an old tree, the cortical layers of which are thick, the shifting of the scion under the bandage is to be apprehended. The way to remedy this is by leaving the cut part of the scion rather thick, or better still, by placing an intermediate substance between the back of the scion and the bandage, for instance, the strip of bark which has been removed from the stock. These strips of bark may be turned down without removing them, and afterwards brought up on the backs of the scions before the bandage is applied. The two seasons suitable for this mode of grafting are March and April, when the sap begins to flow and September and October, just before it goes to rest. The treatment after grafting is the same as that which we have

Veneer Crown-Grafting.

indicated in the case of ordinary crown-grafting. A grafter in our establishment, Louis Asselin, invented this method, but the process is so simple and reasonable that other practitioners must have tried it before him.

VENEERING WITH STRIPS.—M. Trouillet, arboriculturist at Montreuil, communicated to us this mode of grafting. It has some resemblance to "side-grafting with a simple branch." We employ them both with equal success in restoring trees which have lost their branches. The proper seasons for operating by this method are in April with a shooting bud,

Veneering with Strips.

and in August with a dormant bud. With the metro-greffe we cut the scion, on its rounded face in a duck's bill section. We measure the diameter of this, and applying the implement to the stock (x), we cut the bark with the double spatula;

then with the grafting-knife cutting across at the top of the two lines, we bend back the strip (y), fix the scion (v) in its place, and bring up the strip upon it, as shown at (y). It is then bandaged, and grafting-wax applied to the crevices. In operating on strong or much-branched trees, it is wise to cut notches (z, z) half an inch or so above the grafts. These, by arresting the flow of the sap, will divert it towards the new shoots.

TREATMENT AFTER VENEER-GRAFTING.—As the bandage is indispensable, the first care will be to prevent it becoming too tight, and it will require to be well looked after. Soon after spring-grafting, the stocks which have been side-grafted are headed down by degrees, leaving them at last a heel of four inches in length. With subjects grafted in the end of summer, the heading down of the stock is completed after winter. The heel serves for fastening up the scion in the early stages of its development. It is removed after a year's growth. If the object be to produce a lateral branch, the development of the scion is promoted by a notch (z) made over the place of its insertion, and by cutting away the branches growing above it. A stake or prop is useful to fasten the young graft to.

(To be continued.)

C. Baltet.

GARDENING IN BERLIN.

A CORRESPONDENT of a morning contemporary speaks well of the gardening of the Berliners.—Trees dot the streets with delightful irregularity. Save in the Linden, the Bellevue, and one or two other set promenades, there has been no plan observed, no order followed, in the planting of these hearty and hardy old Dryads. Sheer love of the green leaf and its rural associations has evidently prompted some house owner here and there to insert a slip of some favourite tree amongst the kidney stones fronting his house, without notifying his intention to the authorities. There is many a stout, honest tree flourishing exceedingly in what would otherwise be absolutely a stony wilderness, and the whole aspect of the town is thereby brightened up to an extraordinary extent, or to an extent that, at least, seems extraordinary to any foreigner walking through its streets to-day and recalling their appearance during the month of January. The villa gardens that flank the forest's northern side are many of them, masterpieces of horticultural art. In the absence of all evidence of taste in music, in the drama, painting, sculpture, or literature, I had given up the thoroughbred Prussians as utterly devoid of artistic discrimination or love of beauty; so I am rejoiced to find that they possess in a remarkable degree the talent of gardening, as well as a sincere partiality for flowers and appreciation of them. The Berliners are unquestionably great at gardening, and have also a natural bias in favour of flowers. An ex-American Minister observed the other day, *apropos* of the latter fact, that their inclination was doubtless the result of an instinct providentially bestowed upon them in view of the perils they run from mephitic exhalations; vegetable matter being an eager absorber of such gases as are dangerous to human health. This may or may not be the case; but it is very certain that horticulture is at a premium here, and that flower-pots and window-gardens belong to the domestic institutions of the German capital. But what they have done to render theatre-going not only possible but agreeable during the burning summer months deserves honourable mention. Their minor houses, all situated in suburbs far distant from the fashionable centre of Berlin, are with scarcely any exceptions constructed in such a manner that their lobbies communicate directly by broad staircases with large and prettily laid out gardens, in which fountains play. Every door in the auditorium, so to speak, opens into the fresh air.

These practical Berliners not only supplement their theatres with gardens, but all their other social institutions, except their churches—though, as these latter are sparsely frequented at any time of the year, and scarcely at all in summer, it is easy to account for the apparent shortcoming. No sooner has the warm weather shown a lively disposition to set in, than gardens spring up all over the town, frequently in places with which your mind, accustomed to consider them from a winter point of view, has never associated flowers or fountains, and experiences some difficulty in doing. Say you turn it to a familiar restaurant on the Russian Embassy side of the Linden, or in the Friedrichstrasse, or, in fact, anywhere about the Friedrichstadt. Where your hyperbolically educated eye is accustomed to look for a dismal flagged yard, pent in by high, frowning walls, its only ornament, perchance, a ghastly pump, you perceive a sort of excerpt from Fairyland, made up of bright glass, gay flowers, flashing, plashing water, and green shrubs.

WORKING IN THE HEAT.

THAT a tropical climate is specially trying to the health of Europeans is accepted as an axiom. Hence, better salaries are offered for similar service and higher premiums imposed on lives by insurance companies, to compensate for the extra risks to health and dangers to life. All this is received as a matter of course; and yet singularly enough scarcely any note is made of the danger of working in the heat at home. Tropical temperatures are only held to be enervating in tropical countries. The danger of working in the heat at home is, however, greater than exposure to the same temperature abroad. Sudden changes are even more disastrous than a high temperature. A whole host of diseases follow the track of great alterations from heat to cold. These, oft repeated, open up the citadel of life to most of the ills that flesh is heir to. And it is to such extreme changes that horticulturists are particularly exposed. In winter they are constantly plunging from a tropical into an arctic sea of air. It is this that makes them the natural victims of rheumatics, with its racks and thumbscrews.

The evil is by no means a small one, neither in its results nor the numbers affected by it. Every day the area covered by glass is extending, and probably one-half of it is used to furnish tropical climates. The number of workers in the heat keeps pace with this extension of glass. Hence the importance of lessening the risks. Much work must be performed in high temperatures; but by attention to the following simple suggestions the amount might be greatly lessened, to the comfort and benefit of all concerned. A good deal of the work might be done in cooler places; the temperature of the houses could be lowered when work was being done in them; the coolest part of the day chosen for hot work; and the workers so prepared for their labours as to be able to go through them with a minimum of risk. Much horticultural work is portable. All plants in pots are of this character, and the cleaning, training, and potting of these constitute a large proportion of the work done in the heat in most establishments. True, plants are generally removed to a shed for potting; and were sheds are lighted and warmed, as all garden workshops should be, there are good reasons why all cleaning, training, and staking should likewise be performed out of the house. More and better work would be done in less time. The men would be safe, and the plants could take no harm. As I have said, the temperature of the houses might often be lowered with perfect safety while work is being done in them. Take for instance the everyday operations of shutting up and syringing glass-houses early in the afternoon. The most common practice is to shut up first and syringe afterwards. The consequence is the operators are subjected to a Turkish bath. No harm whatever could come to the plants by reversing this order. Syringe first, and shut up immediately. The plants would thus have their bath, and the men escape. And so in regard to thousands of other matters. If done without creating draughts, the temperature of most plant houses may be considerably lowered while necessary works are being performed without injury to the plants; and it is high time that the health and strength of the operatives were taken into some account in our hothouse arrangements.

Again, by choosing the cool of the day for housework, there would be much less working in the heat. Take grape thinning, for example—what a melting affair it is at noon; but in the early morning, or cool of the evening, it is a real delight to the true gardener; and if it must proceed all day and every day till finished, an artificial cool or dull day can be made by thick shading and an extra amount of air. The latter expedient must not, however, be carried too far, lest the tender grapes get a chill that stunts or mars them for life. But by picking out dull days and the cool portions of hot days, drawing out the fires, &c., cool times may generally be made or found for the doing of most irremovable housework.

Finally, the last remedy I would propound as an antidote to the dangers of working in the heat, is the preparation of the worker for his work. When any of the craft are called to India how careful they are about their kit; they choose only clothes suitable for the climate; but at home who thinks of these things? the consequences are suffering through life, premature exhaustion, a pension from the Gardeners' Benevolent Institution, or a total collapse; and all this often for want of the most ordinary precaution to preserve health. There is one protection that every one may use—flannel next the skin; this is a shield of safety against the dangers of working in the heat.

Years ago I knew a young man whom no persuasion could make to wear flannel. He laughed at all coddling, and cared not how hot or cold his work might be. He thought lightly of stepping from 110° in a pine-stove to 40° on the face of an east wall. During early spring it was his habit to go from house to house syringing stripped to his trousers. One keen day in March he came forth from a cucumber house at 90°; the biting March wind struck him as with fingers of ice. His underclothing, wet with perspiration, flapped against his

back like a snow wreath, at the same moment he was suddenly transfixed as if a sharp spear had pierced his spine. He could only stand still and scream. But the first thing he asked for was flannel, and he has worn it ever since. But no season passes without a few shafts sent forth from the old enemy, lumbago. Forewarned, forearmed. Would that the rising race of gardeners would look thus at the matter. Let our sufferings suffice. Why should their lives be also blighted by thoughtless, reckless, unnecessary working in the heat? By the use of flannel and extra clothing before leaving the heat for the cold, by care on the part of the workers themselves, and the exercise of forethought and sympathy on the part of masters, the sufferings borne of working in the heat may be escaped, or reduced to the narrowest limits.

D. BURY.

THE ARBORETUM.

DESTRUCTION OF TREES IN KENSINGTON GARDENS.

THREE large trees in Kensington Gardens have just died, as it would appear, from mismanagement. They stood at the side of the road to the south of the bridge over the Serpentine. Their destruction seems to have been caused by the men employed in making or graveling the path, their collars having been completely buried under the gravel, and even the lower part of the trunks covered to a considerable depth. By such a process the destruction of a tree is, tolerably certain, though the well-known result likely to follow such an operation does not appear to have foreshadowed itself to those who so covered up the trees. The authorities appear ashamed of the affair, as men were employed during the whole of Wednesday night (June 13th) in grubbing them up and removing them by lamplight. These ornaments of the Gardens are gone, and cannot be restored; but I beg to call attention to the fact that there is a whole row of fine trees at the edge of the path which have been "tarred with the same brash," a very rough one, and they will probably share the fate of their neighbours that have perished, unless something be done immediately to save them from that process of burying alive, to which those already gone have succumbed.

We Cockneys, though we may not know so much about forestry and tree-culture as those appointed to rule over our public parks and gardens, are yet very proud of the grand forest trees that supply us with sylvan scenery almost in the heart of London; and their destruction from sheer carelessness gives needless pain to many whose country walk cannot be taken farther afield than the parks or Kensington Gardens. Great regret was felt at the death of the noble old elms that perished in consequence of their long imprisonment in the first Crystal Palace. But they died in a great cause; that of the establishment of those international exhibitions of art, and of scientific skill, which each year brings us into more friendly communion with our Continental neighbours.

The present instance in Kensington Gardens has, however, no such excuse; there are no "extenuating circumstances," and it is to be hoped that such a system of destruction may not be allowed to extend its ravages.

W. B. L.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE SCORPION SENNA (*CORONILLA EMERUS*).

This forms a very elegant loose bush, from four to six feet high, with slender and somewhat declinate shoots, which require clipping occasionally to keep the plant compact. It is a native of the middle and southern parts of Europe, is easily increased, either by seeds or by cuttings, thrives well in any good garden soil when placed in a sunny, sheltered, and rather dry situation, and was first introduced in 1596. The leaves are alternate on the young shoots, but crowded together on the other parts. They are pinnate, quite smooth, and more or less persistent, or sub-evergreen in mild seasons. The leaflets are small, inversely egg-shaped, smooth, and in three or four opposite pairs, with a terminal or odd one at the end. The flowers are pea-shaped, and produced plentifully in twos and threes, on longish, slender, axillary peduncles. They are reddish externally before opening, but bright yellow when fully expanded, and the two forms being mixed together on the plant when in flower in May and June, produce a very fine effect. The plant, however, keeps on flowering more or less until the end of September, if in a vigorous state. The legume, or pod, is rather more cylindrical than flattened, and, when

ripe, separated into one-seeded joints. The Scorpion Senna is well suited for forming small ornamental hedges, as it stands clipping well, and continues producing its flowers in succession for a considerable length of time.

THE DOWNTY SPIREA (SPIREA TOMENTOSA).

This forms a somewhat erect bush, from three to four feet high, which flowers more or less from July to October, but in greatest perfection in July and August. It is a native of Canada (on mountains), and of the north-west coast of America about the Columbia, and was first introduced in 1814. This handsome shrub thrives best in a light rich soil and fully exposed situation, and deserves a place in every collection. The leaves are of various shapes, some being ovate or elliptic, and unequally or coarsely serrated, while others are oblong-lanceolate nearly entire, or with only a few serratures towards the apex, but all are furnished with very short tomentum and light green on the upper surface, while the underside is densely coated and quite white in appearance. The flowers are small, deep red, and densely crowded together in compound terminal, oblong, blunt, erect racemes or panicles, with the stamens twice the length of the corolla. The racemes and young shoots are coated with a short dense tomentum of a reddish-brown colour; the lobes of the calyx are triangular and deflexed, with the carpels spreading in different directions. This kind is the same as *Spiraea Douglasii*.

Seaside Planting.—I have succeeded in growing the Aleppo pine (*Pinus halopeplis*) from seeds brought from the Isle of St. Marguerite, opposite Cannes, where this pine grows with its roots down to the salt water, and where it withstands the most terrific sea gales without seeming a bit the worse for them. Those who wish to plant near the sea should plant as follows: *Pinus halopeplis*, Corsican pine, *Pinus insignis*, *Pinus austriaca*, *Picea nobilis*, *Cupressus macrocarpa*.—*C. Down, Ireland.*

Double-flowered Peaches.—Peach trees with double blossoms cannot well be too highly recommended for general cultivation. The following varieties of them are now known: *Mirrored*, *double-white*, *yellow double*, *pink double*, *rose flowered* (*dianthiflora*), *scarlet flowered*, a new and very pretty striped variety, another called *versicolor*, one of Asiatic origin called *Peach of Ispahan*, and the common European double kind. We may remark that in form the last is different from the preceding ones; in fact, it resembles greatly our indigenous peaches.—*Ed. André.*

STRIKE OF THE LONDON MARKET-GARDEN LABOURERS.

WIDESPREAD dissatisfaction has broken out among the men and women who work in the market gardens round London, particularly in the south and south-western districts. They are on strike at Isleworth and some other places. These men receive on an average 15s. per week, some more some less; and the foremen, so called, get generally 20s. per week; women, of whom a great number are employed, receive from 7s. to 8s. per week in summer, and 6s. in winter. The men demand an advance of from 2s. to 3s. a week, or an average of 18s., payment for overtime, and to quit work at four p.m. on Saturdays. The women's demands are similar to those of the men, except that their wages are only to be 10s. a week. Several meetings have been held in reference to the matter, and some of the employers do not object to the terms asked; but, on the other hand, others stand out firmly against them. The effect of this strike is already beginning to be felt both by seller and consumer—the former cannot get his goods to market, while the latter has to pay more for the diminished amount that finds its way there. Considering the loss to all parties concerned, let us hope that some speedy arrangement may be arrived at which shall be alike satisfactory to masters and men.

Incendiaryism in a Market Garden.—At about two o'clock on Saturday morning an alarming fire broke out on the premises of Mr. Norris, market gardener, Sion Hill, near Brentford, doing damage to the extent of between £300 and £400. It is supposed to have been the work of an incendiary. It appears that the garden labourers and women have been on strike in the neighbourhood for higher wages, several meetings having been held, and some of the employers who decline to give the money demanded have received anonymous letters by post threatening to destroy their premises by setting fire to them. The Brentford and Isleworth engines were shortly on the spot, but the building, containing garden tools and baskets, was entirely consumed. At a meeting of the Brentford Fire Brigade on Saturday it was resolved to keep two firemen on duty during the pending strike.

THE LOWER GROUNDS, ASTON.

Our public gardens must wake up, or their laurels may be snatched from them. Of all the sluggish institutions the slowest is the botanic garden, where not supported by the Government. There is no reason why botanic gardens should not be self-supporting; no reason why they should not be attractive to all classes. But they are not so. Why? Because the character of the bodies which govern them is such as to stifle all originality and boldness of resource in the superintendent of the garden. Able and energetic humanity is rarely moulded on a plan which makes it possible to do good work and earn the toleration of all the members of a committee at the same time.

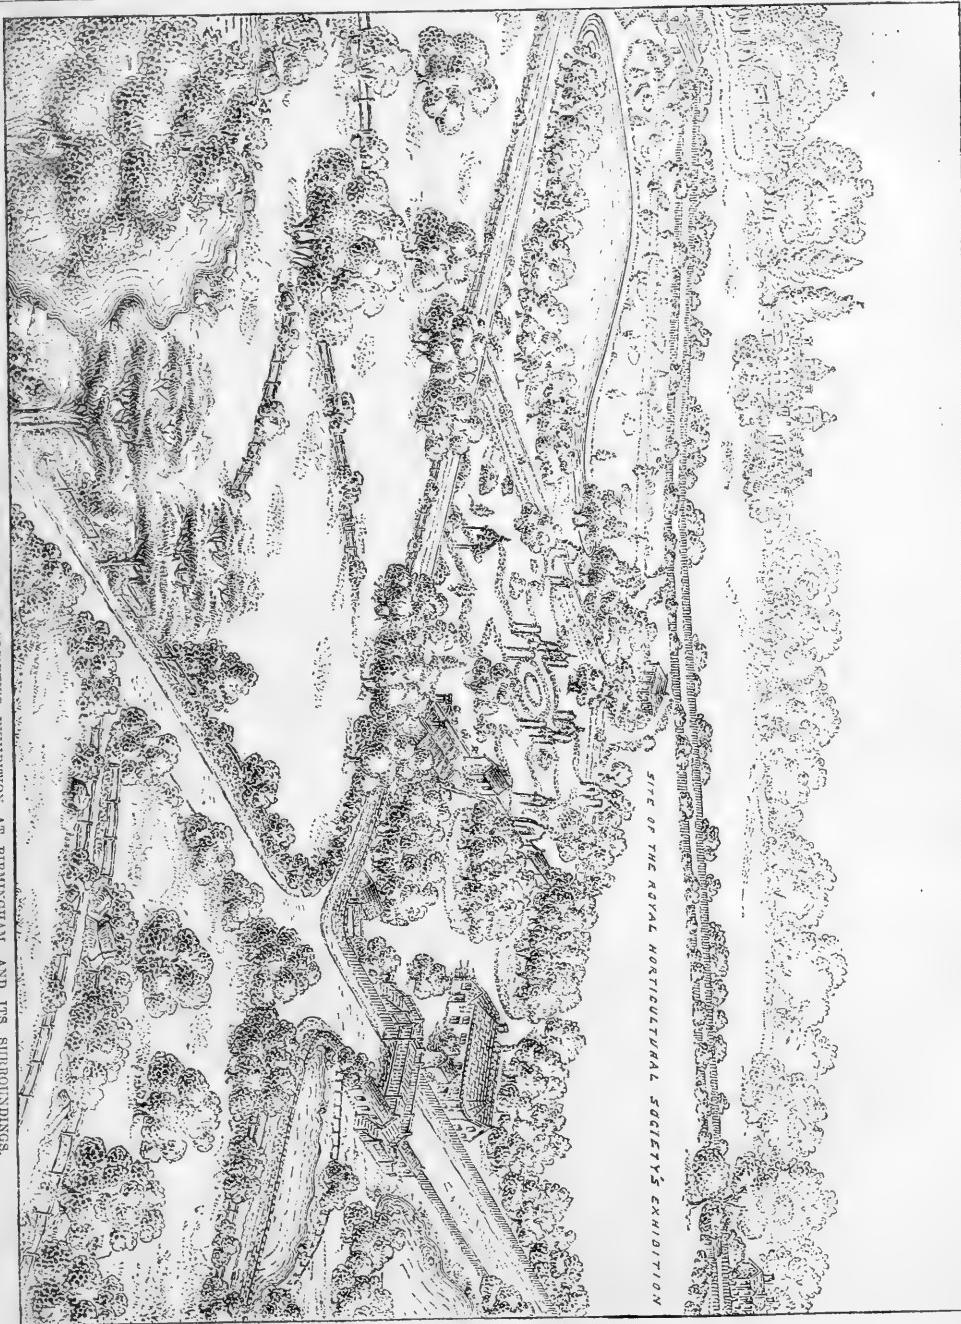

The Lower Grounds at Aston are an example of what may be done by an individual, beginning with few or no advantages, in the formation of a garden, which, to all intents and purposes, is a public one. About eight years ago the Aston Lower Ground, was, as far as gardening is concerned, a waste; now it is one of the most remarkable gardens in the country for both spring and summer plants. The owner, Mr. Quilter, who opens it to the public for payment, has gone into gardening with genuine enthusiasm, and his stock of hardy spring flowers and series of houses for the propagation of bedding plants, and his fine collection of sub-tropical plants and palms, would surprise many of those accustomed to our largest places.

These gardens are so popular with the people of Birmingham and the district that on Whit-Monday nearly 16,000 persons paid to enter them. The main attraction was the display of spring-flowering plants, which were then in all their glory. As an example of formal colour in the flower-garden, the result was most striking, and the number of plants employed enormous. The appearance of the spring flowers here on Whit-Monday bore witness to their supreme importance in our ornamental gardens. The frost of the previous Saturday was such as to blacken and destroy the young spray of hardy forest trees, while, as is well known, the icy showers of the month were most destructive. Yet the pansies, daisies, violets, forget-me-nots, and other dwarf spring-flowering subjects employed, were as rich with brilliant unsold colour as the most carefully tended exhibition plants.

It is matter for congratulation that in a garden evidently designed for the entertainment of the masses, such a step in advance should be taken. When it pays Mr. Quilter to rival the slopes of Cliveden and Belvoir with his many thousand spring flowers, and when the Black Country holiday visitors to his garden see for a few pence the "sub-tropical plants" we have hitherto considered only possible in Battersea—favoured garden of the State—it is probable we are approaching a period when public gardens of a high order will be created for and supported by the large populations of our great cities.

In a field adjoining Mr. Quilter's garden the exhibition of the Royal Horticultural Society takes place. There would be no better evidence of the character Mr. Quilter has endeavoured to impart to his grounds, than that the Society should elect to hold its exhibition in them. Here during the exhibition week, a novel combination of spring and summer flowers will be seen. Mr. Quilter, who plants spring flowers on a vast scale, quite expected to have them removed and replaced by the summer flowers. But the season being so wet and cold, several of the most important classes of spring flowers, as for example, pansies and daisies, looked as well in the early days of June as they had previously done, and Mr. Quilter determined to let them remain. The result is that at present half the garden is brilliantly embellished with hardy spring, and early summer flowering plants, while the rest is planted with summer flowers. Here and there among the pansies, &c., tufts of Cannas may be seen, braving successfully the rigours of a harsh and cold season.

The Parks in Paris.—The Bois de Boulogne is recovering its beauty now; even about the gates of the Porte Maillot and Avenue de l'Impératrice, where its appearance was so terribly marred; the brilliantly green shoots are rising rapidly, and make a pretty fringe to the wood, unequal as that green fringe is to the cool, thick shade of old trees one used to look directly into under the sun. The long terrace that slopes down from the gate built in the place of the levelled lodges. During the sun afternoon parties of children went through the green grove of infant trees, just a little taller than they, picking the seed grasses and flowers that spring up in quantities on the cleared ground, and the scene made the prettiest spring picture imaginable.

PLAN OF THE SITE OF THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION AT BIRMINGHAM, AND ITS BOUNDARIES.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)
BY OUR SPECIAL REPORTER.

PRIVATE GARDENS.

Indoor Plant Department.—In order to keep our conservatories gay with flowering plants, large hard-wooded plants in pots are moved to some sheltered place out of doors during the summer months. Some of the most effective of them are also turned out into the sub-tropical garden. The prevailing vegetation indoors now consists of Fuchsias, Pelargoniums, Salvias, late Calceolarias, Balsams, Cockscoubs, &c. Besides these, baskets ornamented with Lobelias, Tropaeolums, Ferns, Tradescantias, variegated grasses, and even Begonias, are liberally employed as objects of indoor decoration. Plants of Achimenes in pans, staked out rather broadly, are placed in shady parts of the conservatory; Gloxinias in pots are likewise now brought into this structure and are placed in positions in which their foliage can be kept dry and their flowers shaded from direct sunlight.

Pits and Frames.—Frames that have been occupied by Calceolarias and similar plants, have a few inches of the mould thrown out, and replaced by a good rich compost, in which Vegetable Marrows are planted. Chrysanthemums are now freely exposed, shifted according to their requirements, stopped, syringed, and occasionally turned, to prevent one-sidedness. A few Verbenas are still kept in pots in gentle heat, to furnish cuttings to replace such plants as become exhausted before the autumn. Hollyhocks from seed are potted singly, and set in cold frames, others are being increased from sideshoots, and placed in similar positions. Calceolarias sown in pans of light soil, have a piece of glass placed over them; they are then set on a gentle hotbed and shaded.

Flower Garden and Shrubbery.—The sudden change that has taken place in the weather has forwarded bedding-out wonderfully. All the commoner kinds of summer decorative plants have been put out, and now sub-tropical gardens occupy attention. In the case of Alternantheras, screens of canvas are put up, so as to prevent too strong sunshine from injuring them. After planting, a good soaking of water is given, and evaporation is prevented by mulching, as it were, with some dry earth. Roots of Hyacinths, Tulips, Anemones, Ranunculus, &c., are being lifted, dried, and stored, or planted in the reserve ground, and the open space that has been occupied by them is filled with summer-flowering plants. Pinks and Carnations in beds are neatly staked, and the surface of the soil kept clean and loose. Pyrethrums are also supported by single stakes. Where flowers of these are wanted in autumn, they are cut down and allowed to start afresh.

Indoor Fruit Department.—Pines receive little shading, but a free circulation of air is given, and a very humid atmosphere maintained by sprinkling the paths, walls, and beds with water. To the roots of swelling Pines a little weak manure water is given. Shutting up early saves fire heat. Unproductive plants are turned out of their pots, their balls and roots are reduced, and they are repotted into smaller pots and plunged in bottom heat with a close moist temperature. Vines relieved of their fruit are induced by every means to ripen their wood. Such as are ripening fruit are kept a little drier than ordinary, whilst such as are only swelling enjoy a humid atmosphere. Pot vines receive a little manure water. Late vines have a little fire heat when in flower.

Hardy Fruit and Kitchen Garden.—The young shoots of fruit trees on walls are being tied in, so as to get better ripened and in order that they may not obstruct light and air from the fruit. Where too many young shoots are coming up in the middle of fruit bushes they are removed. Frames are being erected amongst Strawberry plantations, which will be covered over with herring nets, to keep off birds. A good deluge of sewage or manure water is given to them, but as soon as the fruit begins to colour stimulants will be discontinued. Strawberries on warm borders exposed to the midday sun have already produced fruit. Supports are being placed amongst Gooseberry and Raspberry bushes intended to be kept for dessert, so that the nets may be placed on them at any time. The main crop of potatoes is being earthed up, and in the alleys between, Scotch Kales or Broccoli are planted, and at the same time well watered. Turnips are again sown, but where obtainable from the fields no more sowings of these are made in the garden. Carrots and Beets are being thinned. Salsify and Scorzonera are also gone over and thinned. Leeks from March sowings are being transplanted. Another sowing of onions is being made in four-foot wide beds, for drawing when young for salading. The main spring sowings are cleaned, thinned, and where sprinklings of Carrots or Lettuces were also sown with them they are removed as they become fit for use. Tomatoes are planted out against the foot of walls,

leaving little basins around their base to retain water. Early Peas are now podding freely, and later sowings promise a good succession. Mildew has not yet made its appearance, but this malady is guarded against by drawing the earth to the plants in such a manner as to retain moisture, dryness being a fruitful source of that evil. A sowing of the Auvergne Pea is being made for late autumn use, as is also the latest main crop of Beans, and advancing crops earthed up and pinched. Regular successions of French Beans and Scarlet Runners are being made, and the latter staked. A sowing of Orach and Lamb's Lettuce is being made. Successional sowings of Lettuce, Radishes, and other small salads are being put in on cool shady spots. Fresh plantations of New Zealand Spinach are being made in lines, the seedlings are thinned to a proper distance apart, say twelve inches, and the refuse used for transplanting. Asparagus cutting is given over for a season. Work in the kitchen garden consists mostly in the destruction of the weeds and loosening the surface of the soil.

NURSERIES.

Indoor Department.—Bright weather, like that with which we are now favoured, causes an extra quantity of shading to be applied to glass houses; which are much more shaded, as a rule, than those of private gardens, the main object being to produce young growth and increase the size of the plants irrespective of flowers. Plants of Cyanophyllum, Sphaerogyne, Medinilla, &c., as they fill their pots with roots get another small shift, and are kept in a damp, warm house; and they are frequently syringed, and their foliage preserved from being broken or deformed. Sanchezia nobilis is also shifted as required, and the leaves occasionally sponged, using water in which soft-soap has been dissolved. Costus elegans is not supplied very liberally with water unless growing freely. Alocasia macrorhiza and metallica are being repotted and kept in a moist, warm house; some people keep them standing in inverted pots over a water-tank. Caladiums are reported as they require it, and kept densely shaded. Young Dracennas, from pieces of the root and stem, are potted singly and kept for a time in close frames in the propagating pit.

Outdoor Department.—Outside work consists chiefly in cleaning the ground, and in watering newly-transplanted shrubs, also herbaceous plants in beds. Young fruit trees are being trained and superfluous shoots removed. Attention is also given to the displacing of suckers both from roots and stems. Fruit bushes, unless grown for training purposes on walls or as espaliers, have all central shoots displaced. From young Raspberry bushes, the weakest shoots are removed. Cuttings of Aucuba, Box, Holly, &c., inserted under hand-lights a year ago last autumn, are now being lifted, potted singly into small pots, and placed for a time in well shaded cold frames. The compost used for them is a strong yellow loam mixed with a little well-rotted manure and sand.

MARKET GARDENS.

DURING the cold damp weather which we had in May, the hardier vegetable crops grew well, but those of a more tender character, such as French Beans, Vegetable Marrows, Cucumbers, and Tomatoes, suffered considerably. French Beans have, however, now started in earnest, and are progressing admirably; as are also other crops. Asparagus, owing to the weather, has been more meagre than usual this year, but strong crowns nevertheless continue to yield good cuttings. Seeding Asparagus is coming up nicely, and is encouraged by being kept clean and frequently stirred; last year's sowings that were transplanted this spring are now strong; three-year old plantations have been yielding heads for table this spring. When an old plantation is to be broken up, it is cut from as long as marketable heads will pay for the trouble. Main crops of Brussels Sprouts have now been planted. Savoys are planted in lines between fruit bushes, and are at the same time well watered. Cabbages are planted if necessary; but most of that kind of work having been done during the damp weather, no more is done at present than is absolutely necessary, except perhaps in sheltered places, such as between lines of fruit bushes or under trees. Sprouting Broccoli, of which the principal winter supply consists, is being planted between rows of bushes. A few Lettuces are sown in a cool, shady place. Globe Artichokes are supplying heads abundantly; the ground is hoed, and in some cases a mulching of litter is applied. Ridges in course of formation for Celery are at present being cropped with Endive or Lettuce. Parsnips, Carrots, and Beet, continue to be thinned. To the last transplanted crop of Leeks a good watering is given, and the soil afterwards hoed. Tomatoes are being planted out about three feet apart. Vegetable Marrows are fully exposed throughout the day, especially such as are established. Failures are made good from reserve stock. Frame Cucumbers receive plenty of air throughout the day, and some litter is shaken over the glass to act as a shade.

PLAN OF PROSPECT PARK BROOKLYN, NEW YORK.

development of individuals, which will be further encouraged by the best attainable conditions of soil and situation. In the central portions of the park is an open grove of forest trees, in which visitors may ramble in the shade without impediment of underwood, and without danger of doing harm to anything through carelessness or any ordinary selfish impulse.

A collection, arranged in the natural way, of the choicer evergreens, both coniferous and of the class denominated in England "American plants," such as Rhododendrons, Kalmias, Azaleas, and Andromedas, is tastefully grouped on the interior slopes of the "Look-out" and the "Friends' Hill," and in the valley between them, where, from the peculiar circumstances of exposure and protection, they will be likely to thrive. The whole is well and profusely planted.

It would, however, occupy too much of our space to describe the whole of the features of this remarkable park, in which we only saw two errors. The first is the one carried out to a greater and more objectionable extent in the Central Park—the making of a number of bridges for which there was no occasion whatever. The alleged reason for these bridges is that it is desirable to keep the carriage and equestrian traffic separate. Imagine the drive in Hyde Park bridged over to allow the horsemen to cross it, instead of doing as they do at present! But this is quite a transparent piece of absurdity; the real reason, no doubt, arose from the desire to create many second and third rate architectural features in the park; for vast cities are not sufficient for the architects, they must thrust mediocres work upon us in the very place where even all the necessary structures should be partially or quite hidden. Another error here was the construction of a good deal of the plum-pudding species of rockwork, i.e., the sticking of large stones into sloping banks not otherwise objectionable. This would be wrong anywhere, but it is peculiarly so in any park lying in what is practically as much New York as Lambeth is London. Now, the Central Park contains the noblest croppings up of natural rock we have ever seen in a park—public or private; but as nothing of the kind occurred in the Brooklyn Park, it was unwise to attempt puerilities of this kind with such grand examples so close at hand; the wisest plan would have been to dispense with rockwork entirely, and to encourage the development of other distinct features.

THE FLOWER GARDEN.

ANNUALS FOR SPRING.

It is certain that those who have not raised annuals for spring flowering have not enjoyed them in their beauty. And yet it seems to be comparatively seldom done. The colours of spring flowers are, as a rule, purer and brighter than those which come later, and this is enhanced by their sombre surroundings. There is nothing in the summer or autumn garden which can give such an exquisitely pure piece of colour as crocuses of different colours scattered over the turf on a sunny day in spring; nothing so gem-like as hepaticas, or so fragrant as violets. But this has been said a thousand times. The object of this note is to induce amateurs to raise some annuals next autumn, so that they may enjoy them as they never enjoyed them before.

Nemophilas, for instance, sown in the beginning of September in rows, and thinned out, may be moved to the flower garden when the summer bedders are removed. Let each plant be quite a foot apart, and the brilliancy and duration of bloom will surprise those who have only seen spring and summer sown annuals. Mine began this year to flower in February, and are now (June 12th) at their very height—that is four months of bloom from an annual. Sweet Peas sown at the same time came into bloom last week. That exquisite annual, Leptosiphon roseus, will not do for spring flowering, but it stands the winter quite happily. Last autumn, after having bought and sowed some of it, as a new annual, I happened to see some beds of it in a garden near Edinburgh, and was much disappointed at its shabby appearance. But my autumn-sown plants are a different thing altogether. They flowered too late for the spring garden, and had to be transplanted (for the second time) when just coming into flower. They are now splendid, and the neat habit and brilliant rose colour of the plant make it, for some purposes, where neatness is required, quite the best annual we have. It is a capital thing for dotting over rockwork.

If possible, devote a part of the garden to autumn-sown annuals,

where it will not be necessary to root them up at the height of their beauty to make way for bedding plants; and, above all, keep them well thinned, and treat them generously.

SALMONICEPS.

MORINA LONGIFOLIA.

The thistle-like leaved plant cultivated in gardens under this name from its first introduction by Captain Madden some thirty years ago, is, I believe, more correctly referable to the *Morina persica*, a native of the northern mountain districts of Persia, and also extending eastwards to the Eastern Himalayas. Certainly, it is not the plant figured under that name in the "Plantes Asiaticæ Rarioræ," which is of a much more slender habit. Be this as it may, it is one of our best hardy border plants.

Unfortunately its thistle-like appearance has, in more instances than one to my knowledge, militated against its general introduction, the gardener's hoe having made a clean sweep of it as a worthless weed long before it had unfolded its beauties.

I well remember, when serving my apprenticeship, seeing it placed in the thistle section of Compositæ, and I also remember my astonishment when its blooms indicated a very different position in the natural arrangement. Never was hen more surprised at her fresh-hatched brood of ducklings, than was I at the flowers which this plant produced; for in place of the capitula of the supposed order, it sent up long spikes furnished with foliaceous bracts, every serrature of which was terminated by a long stiff mucro, and out of these protruded long tubular flowers, at first white, shading off to rose colour on the second day, and to a deep crimson on the third, thus giving a peculiar beauty in the variety of tints. These spikes have somewhat the appearance of the Acanthus family, but it is really referable to the order Dipsaceæ, and not remotely related to our Fuller's Teazle.

The following brief description of this plant when well grown will give some idea of its value as a herbaceous plant. From a mass of foliage by no means inelegant, rose some eighteen spikes of bloom, varying in height from two to three feet, each erect and capable of holding its position without the assistance of any stake; the lovely flowers—some white as snow, others rosy as peach blossom, and others again crimson as blood, drooping over the fortified battlements that each set of bracts might be said to represent—presented a *tout ensemble* no less beautiful than singular. This plant blooms in the month of July, and thrives well in any deep garden soil; showing, however, in its more vigorous growth a liking to a stiff retentive loam, in which the specimen I have alluded to has flourished for five or six years. It is very impatient of removal when once fairly established, but it seeds freely, and is readily increased in that way. To those who would secure this desirable, and by no means common, border plant, I would tender this advice—always choose a seedling in preference to an old plant; the former begins at the "beginning," the latter more frequently than otherwise begins at the "ending."

Botanic Gardens, Hull.

J. C. NIVEN.

THE CANNAS.

If there were no plants of handsome habit and graceful leaf available for the improvement of our flower gardens but these, we need not despair, for they possess almost every quality the most fastidious could desire, and present a useful and charming variety. The larger kinds make grand masses, while all may be associated intimately with flowering plants—an advantage that does not belong to some free-growing things, like the Castor-oil plant. The Canna ascends as boldly, and

spreads forth as fine a mass of leaves as these, but may be closely grouped with much smaller subjects. The general tendency of most of our flower-garden plants is to assume a flatness and dead level, so to speak; and it is the special quality possessed by the Cannas for counteracting this that makes them so valuable. Even the grandest of the other subjects preserve this tameness of upper-surface outline when grown in great quantities: not so these, the leaves of which, even when grown in dense groups, always carry the eye up pleasantly from the humbler plants, and are grand aids in effecting that harmony which is so much wanted between the important tree and shrub embellishments of our gardens and their surroundings, and the dwarf flower-bed vegetation. Another good quality of these most useful subjects is their power of withstanding the storms of autumn. They do so better than many of our hardy shrubs and herbaceous plants, so that when the last leaves have been blown from the Lime, and the Dahlia and Heliotrope have been hurt by frost, you may see them waving as gracefully and as green as the vegetation of a temperate stove. Many of the subtropical plants, used for the beauty of

A Flowering Canna.

their leaves, are so tender that they go off in autumn, or require all sorts of awkward protection at that season; but the Cannas last in good trim till the borders must be cleared. All sheltered situations, places near warm walls, and nice snugly warmed dells, are suitable positions for them. They are generally used in huge and ugly masses, but their true beauty will never be seen till we learn to place them tastefully here and there among flowering plants—just as we place sprigs of graceful fern in a bouquet. A bed or two solely devoted to them will occasionally prove very effective; but enormous meaningless masses of them, containing perhaps several hundred plants of one variety, are things to avoid and not to imitate.

As to culture and propagation, nothing can be more simple; they may be stored in winter, as readily as potatoes, under shelter in the houses, in the root-room, or, in fact, anywhere if covered up to protect them from frost. And then in spring, when we desire to propagate them, nothing is easier than pulling the roots in pieces, and potting them separately. Afterwards it is usual to bring them on in heat, and finally to harden them off previous to planting out in the middle of May; but a modification of this practice is desirable, as some kinds

are of a remarkably hardy constitution, and make a beautiful growth if put out without so much as a leaf on them. The soil for all Cannas should be deep, rich, and light.

Considering their diversity of colour and size, their graceful pointed habit and facility of propagation, we must concede to Cannas the first place; but their capability of being used by anybody who grows ordinary bedding-plants, and the fact that they may be preserved so very easily through the winter, enhance their value still more. Cannas, protected by a coating of litter, have been left out in Battersea Park through severe winters, and during the unfavourable summer of 1867 attained a height of nearly twelve feet. Where it is desired to change the arrangements as much as possible every year, it may not be any advantage to leave them in the ground, and in that case they may be taken up with the bedding-plants, and stored as simply and easily as carrots. Wherever they are grown as isolated tufts, in small groups, or in small beds, it will be best not to take them up oftener than every second or third year. These noble plants would also adorn the conservatory, which is often as devoid of any dignified vegetation as the unhappy flower gardens which are seen all over the country. Few subjects would be more effective; none more easily obtained.

Spring and Summer Bedding Combined.—I have tried to keep a few small beds in my garden continually filled, without disturbance, with a succession of hardy flowering plants. The beds are circles, five feet in diameter, and are planted with single or double anemones (only one kind and colour being allowed in each bed) and purple Clematis, Jackmani or rubella. The clematis are tied down to a wire frame, low enough to admit of the anemones flowering over and hiding them. By next month the anemones will have died down, and the clematis will cover the frame. About eight inches margin is left for an edging. In November the clematis will be cut down, and the frame removed for manuring the bed. This will, I fear, be a difficulty, as it may injure the bulbs; as yet all have done well, and though the clematis have made strong shoots, they are not visible except on close inspection among the anemone flowers.—J. H. W. T.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Mountain Catsfoot.—This pretty alpine plant (known and popular in good collections as *Antennaria dioica rosea*) is grown here and there in the cottage gardens of Warwickshire as an edging plant. As such it is among the neatest of silvery leaved plants at all times, and very pleasing when the dwarf cushions are studded with the little everlasting flowers.—W. R.

The Armenian Grape Hyacinth (*Muscari armeniacum*).—This is a very distinct and striking species, with flowers of a fine cobalt blue, marked with three small yellow dots near the mouth, and produced in dense spikes $\frac{1}{2}$ inches long. They are also slightly but agreeably fragrant. It is, as yet scarce, but will I hope one day be as much grown as any spring flower, as it certainly seems finer than any of the other Grape Hyacinths, though those are among our prettiest flowers.—E. V.

Ondinea galapagoë.—This pretty little shrubby plant has been flowering for the last six weeks round London, and is now profusely ornamented with white rose-coloured flowers. It is a capital subject for planting among dwarf rock shrubs or for the mixed border, and is not fastidious as to soil, for it thrives perfectly in the London clay.—T. S.

Crinum capense.—This fine bulbous plant, often an occupant of our stoves or hothouses, succeeds well planted in the open border in the front of a lean-to house at Messrs. Osborn's nursery at Fulham. In this position it thrives amply, and this spring it has thrown up three stout flower-stems. Doubtless it would succeed in many warm sheltered borders if planted in good sandy loam.—U.

Dianthus brachanthus.—I saw a plant under this name at Kew a few days since, which seems likely to be a first-class plant for choice rockwork. It is a diminutive species, with neat rosettes of slightly glaucous leaves, pink flowers, which are rather freely produced, and is a native of Spain. Can you or any of your readers tell me if it is obtainable in the trade?—SHEEN.

Mic in the Rock-garden.—I saw the other day in Mr. Lowndes' garden, near Broseley, many of the ornaments of a pretty series of rock-gardens much injured by mice which had many runs through them. In some cases strong kinds like Achillea aurea looked as if grazed down by cattle. It may be useful to record the fact, in gardening we do not always know the enemy that destroys our plants.—W. R.

Silvery-leaved Saxifrages.—I am much pleased with edgings and tufts of these; they look so well at all seasons. Will you kindly tell me what kinds I may try in this way with hope of success?—FLORA.—[The following six kinds are among the best.—S. Aizoon, Cotyledon, ligulata, longifolia, pectinata, and recta.]

Best Varieties of Iris.—I am very fond of these noble flowers for planting in rough places and by the grassy margins of ponds, and should be glad you would tell me the names of the best and most diverse kinds. I think these are the best under a good deal of the seeming confusion: that one seen among them and which results entirely from no wood-cutting out, kinds that have no really distinct character.—VICTORIA.—[*Iris germanica*, or its vars. *pumila*, *strenuosa*, *ochroleuca*, and *lorentina* are all good and distinct kinds.]

SUBSOIL DRAINAGE AS SANITARY WORK.

At a meeting of the Association for the Promotion of Social Science, at which a paper, "On the Haunts of Typhoid and other Fevers, in England and Wales," was read; Mr. Edwin Chadwick, who presided, said:—Subsoil drainage, which removes surplus water, and makes soils permeable for agricultural production, besides being a great agricultural, is also a primary sanitary work. By even the imperfect ditch drainage, as I deem it, of the Fen districts, ague has been so much reduced that ounces of bark are now used where pounds were employed formerly. In my report of 1842, on the sanitary condition of the labouring population, there is a chapter of testimonies on the improvement of the health of the population that has followed subsoil land drainage. As a member of the first General Board of Health, I went into the subject thoroughly, and prepared minutes of instructions from comprehensive practical information, as to the subsoil drainage of lands forming the suburbs, as well as the sizes of towns. It is a subject grievously neglected from want of knowledge by medical officers whose education in preventive medicine is imperfect, and who commonly assume that house drainage and sewage is almost the only sanitary work to be regarded. Why, here, in the metropolis, after the prevalence of easterly winds over the Kent and Essex marshes, there is more of ague than appears in returns, and at times marsh diseases of a peculiar type; and surveys and preparations were made for the agricultural drainage of those marshes as a measure necessary for the sanitary improvement of the metropolis; but that measure has hitherto been neglected. Of the drainage works carried out under the Public Health Act within the towns, one effect was the subsoil drainage of some of the sites, as denoted by the lowering of the wells. On a cursory examination, as I might show, and a report by a medical officer of the Privy Council on the results obtained by the works in those towns, it appeared that there had been a marked reduction of cases of phthisis. And it was put forth on out-door experience, that reductions of inflammations of the lungs, as well as ague and typhus, were attendant on subsoil drainage works. Indeed, I have always understood that pure air—and dry air, if possible—was the desideratum for incipient phthisis. There may be some moisture, but it is essential that it should be pure moisture, which the moisture from ill-drained and surcharged subsoils rarely is. Sir John Pringle, one of our earliest sanitarians, gave instructions to note where wells were near the surface, for he had observed that such sites were bad camping grounds. On such facts, instructions embodying the best obtainable experience in agricultural engineering were prepared for the drainage of suburban lands, for the protection of the health of the population of towns and rural districts, as well as for agricultural production. But these instructions have been ignorantly and heedlessly neglected. The necessity of subsoil land drainage for health, as well as for agricultural production, is a leading condition that requires drainage areas, and lines of watershed from the hill tops to the dividing river of the valley bottom, as areas of sanitary administration, independently of the areas for other administrative purposes. I may show the enormous waste as well as obstruction to sanitary work, created by ignorance and neglect of this one condition of the drainage areas for the metropolis. Notwithstanding all that has been said on the subject—I have it on the authority of Mr. Bailey Denton—for every acre of land in this country that has been subsoil-drained more than twelve require drainage. This is a work which public administration may, and ought, powerfully to aid. The most common obstruction to subsoil drainage is the want of outfalls. These, I have shown, may be provided for on contiguous lands by an improved road drainage, which is necessary to the maintenance of the roads themselves. The sanitary engineer—and there must be such engineers for efficient and economical sanitary work for a district—should be a scientific road engineer. This, again, leads to extended drainage areas, as efficient and economical sanitary areas, which at this time require to be considered in the pending legislation.

WATERCRESS.

THERE are many edibles, natives of our own country, hawked about the streets, of which we might be supposed to know more than we actually do. The watercress is one of them, and most of us no doubt have seen it growing where nature has placed it, in some shallow and remote stream. Many who love a ramble in the fields in search of wild flowers have halted by the side of some refreshing brook to gather the watercress; but it is not from the pleasant brooks and streams of England that our markets are wholly supplied, or the best quality of watercress is grown, for like other edible plants, it is improved by cultivation.

Watercress thrives best in springs or clear running water, where the bottom is either sandy or gravelly; and in such a situation it

will sometimes grow a foot above the surface, though its more usual height is about six inches above the water. It has, as is well known, smooth, shining, very often brownish-green leaves, composed of five or seven ovate or rather heart-shaped leaflets. The edges of the leaflets are very slightly sinuated or waved, which is a very good characteristic to distinguish them from those of the water parsnip, with which they sometimes get mixed, and which are decidedly serrated or saw-toothed.

Watercress has been introduced into North America and into some of the British Colonies. In New Zealand it forms a stem as thick as the wrist, almost choking up many of the rivers. Housewives of a few generations back gave to their children, in the spring of the year, a "health-giving" draught, which was a decoction of watercress, brooklime, scurvy grass, and oranges. It is said that the ancients ate watercress chiefly with lettuces, the stimulating properties of the former counteracting the coldness of the latter. The first attempts to cultivate watercress by artificial means in Europe appear to have been made, about the middle of the sixteenth century, by Nicholas Meissner, in the numerous streams which abound in the vicinity of Erfurt. The water and soil suiting the plants, they thrived, and their cultivation became a great pecuniary success. Cresses grown at Erfurt were, and are still, considered of superior quality, and are sent in large quantities to the markets of Berlin, a distance of about 150 miles. In the early part of the present century, the cress plantations of Erfurt were so profitable that they were let by the authorities of the city to the cultivators at the yearly rent of £2,400; and the value has since that period considerably increased. The crops have been known to realise, in one year as much as £8,000. Watercress plantations have since been established in the neighbourhood of Paris, as the demand in the French capital, in its more prosperous days, was very great, the estimated annual value of the cress sent to the Paris markets exceeding £37,000. For conveyance from the plantations, the cresses are packed in large baskets, containing many dozen bunches each, in such a way as to leave an entirely open space down the centre of the basket, which admits of a free circulation of air. The whole are then well watered before being loaded into the waggons, and they are thus delivered quite fresh at the markets.

We read of watercresses once growing in large quantities in the waters of Totthill Fields, Westminster, and even on the neighbouring banks of the Thames itself; but the first we hear of their cultivation, in anything like a regular manner, in England, was in the year 1808, at Springhead, near Gravesend, where they are still grown, and the cress there is noted for its superior quality. When the success of this plantation became known, others soon started in many parts of the country where natural and suitable springs existed. In the neighbourhood of London especially were these watercress beds formed, some of which were many acres in extent; some still exist, some have been done away with, and some new ones have in course of time been formed, the produce being nearly all consumed in London; indeed, the supply is scarcely adequate to the demand. Some of the most noted watercress plantations in the neighbourhood of the metropolis are at Uxbridge, Rickmansworth, and Waltham Abbey. Watercresses are also grown to some extent at Hackney and several other places near at hand, and at one time quantities were even brought to London from Salisbury.

Some idea may be had of the importance of this branch of trade in London alone, when we state that it is computed that between 6,000 and 8,000 bunches are daily brought into the markets, and that the sum annually realised from the sale of watercresses exceeds £10,000. Watercress is undoubtedly a wholesome plant, and an excellent anti-scorbutic; and there are but few to whom it is not agreeable in its fresh green state. It is, moreover, sometimes cooked for table in a manner similar to celery.—*Food Journal.*

A QUESTIONABLE SPIRIT.

"THE New Tea Spirit, Robur"

About the walls we see.

What Spirit, from so sober

A beverage as Tea?

And Tea with "Robur" naming

Together seems a joke

Some explanation claiming;

As "Robur" stands for oak.

If leaves could be fermented,

And were a Spirit made

Of some which are presented

For tea-leaves in the Trade;

Then Robur, in all reason,

Would be its name, right due:

Those leaves that King of Trees on,

The *Quercus Robur*, grew.

—Punch.

THE LIBRARY.

"MY GARDEN."

This is one of the most remarkable books issued on gardening for years; and not so much for what it endeavours to teach as for the immense amount of interest which it shows a garden offers to those who seek its charms intelligently. The author has little that is new to teach in our art, but assuredly we never had a better guide as to how to enjoy a garden. Every phase of gardening seems alike pleasing to him, from fern-growing to vine-growing in what he calls the "Poor Man's House." Judging by the many capital illustrations in the book, the author would appear to be a very enthusiastic and successful fern-grower. He says:—

"The land as well as the water of my fern glen, is well furnished. As we enter it we see gigantic osmundas rearing their stiff and majestic forms; enormous lily ferns gracefully showing their flowering feathery forms, with the noble broad ferns expanding

'lily of the field' expands its beautiful flowers in autumn with such effect that 'Solomon in all his glory was not arrayed like one of these.' A cranberry plantation is arranged on the slopes towards the stream, so that the mind is led from this weak horticultural share to the real glorious natural scenery of Zermatt and the high Alps, where such plants delight to grow. . . .

"I have five outdoor ferneries and one indoor fernery. As a general rule, I think it advisable that they should be arranged below the level of the ground, and in a spot capable of drainage, as a uniform moisture to the roots is thus insured. In a natural state, wherever we see ferns growing luxuriantly, there bank of earth rises above them, so that the roots derive continuous moisture from water percolating through the soil. When this condition is reversed, and the ferns grow on the top of a mound, they are apt to die from drought. Whenever a stream of water can be introduced near the ferneries, it is desirable; ferns suffer no harm, but on the contrary derive great benefit, from the roots being occasionally drenched for a few hours.

"Experience has taught me that ferns like an abundance of light, although it is necessary to screen them from cold winds. For this

Fern Dell in Mr. Smees's Garden at Beddington, Surrey.

their curved fronds to view. Every stump glistens with the golden-spored common polypody, and near every stone the triangular oak fern shows its fronds. Turning round, another view discloses alpine polypody, marsh fern, beech fern, and oak fern. *Cystopteris* grows luxuriantly. The beautiful *Asplenium Trichomanes* and *A. Adiantum nigrum* are healthy, but to the observing eye only do the *Woodsia*, the filmy ferns, and the Killarney fern appear. The grass of *Parnassus* abundantly lends its aid to decorate so lovely a spot, mosses of many kinds appear, and the Northern cloudberry and *Rubus arcticus* grace the scene with their presence. American adiantums flourish, and little tiny pond shows frog-bit, the water soldier, and other aquatic plants. On emerging from the glen we have to traverse little tiny mountaints, such as children might make as toys, but these are lit up with alpine snapdragons, the lovely gentians, primulas, and other alpine plants, with sempervivums at the apices of the stones, and many terrestrial orchids at their base. Here the

reason I always contrive that a belt of trees, or of rootwork or rockwork, shall surround my ferneries, and at the same time that the light of the sky may fall upon them from above without their being directly exposed to the fiery rays of the sun. My fern glade is placed on one bank of the Backwater, and is screened from the sun by a row of nut-bushes to the south. Here many of the larger varieties of lady ferns, interspersed with polystichums, broad ferns, mountain ferns, and scolopendriums, are grown. The royal fern flourishes near the river (the Wandle), but it is advisable to keep the crowns well above the water, as their roots like damp soil rather than wet. In the driest spots we grow polypody (*Polypodium vulgare*), and in the wettest the marsh fern (*Lastreum Thelypteris*). . . .

"My fern glen has given me so much pleasure that I strongly advise everyone who has a waste piece of land near his garden to make a fern glen. It will be a pastime in the winter evenings to design it; the construction of it—the transforming of the ideal conception of the mind into a living reality—will afford much pleasure; many a country trip in the woods will be required to furnish it; and when furnished it will afford a spot for contemplation

and enjoyment, in which the designer may fancy that the robins, warblers, and nightingales, which never fail to dwell there, are pouring forth their gratitude for the construction of such a delightful retreat. . . .

"In my five outdoor ferneries I have three distinct classes of ferns : firstly, those which remain in the ground the entire year; secondly, those which are bedded out during the summer; thirdly, those which are placed out in their pots, and taken back to the greenhouses in autumn. A very large proportion of all ferns which are grown would be benefited by exposure to the pure air of heaven during the months of June, July, August, and September."

Reeds and many other picturesque hardy plants are also used by Mr. Smeee in a very happy manner in the embellishment of his grounds, as shown in the accompanying illustration.

To turn rapidly from the aesthetic to the edible side, so to say, we find a very useful structure described by Mr. Smeee as the "Poor Man's House."

"A glass structure exists at my garden, which is really nothing more than a large frame, so constructed that the gardener can get in and walk along. We call it the 'Poor Man's House,' because it is erected so cheaply and answers so efficiently. To construct a Poor Man's House, a hole is sunk in the ground $2\frac{1}{2}$ feet wide and $2\frac{1}{2}$ feet deep, and the earth so removed is placed at the back of the house. If the water-level of the ground permitted, and drainage could be procured, the whole interior of the house might be lowered two feet more; by which device the house would be well sunk in the ground. A single glass roof is fastened over the sunk part, and ventilation is provided by a board hung upon a hinge at the back.

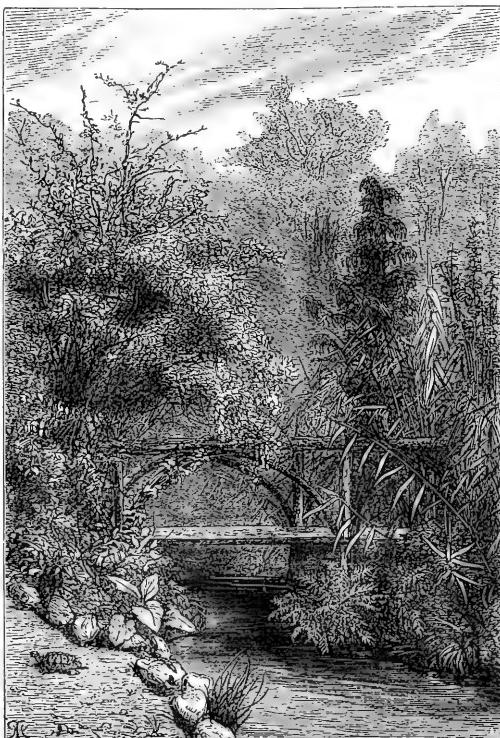

"My Poor Man's House is forty-eight feet long, and the width of the glass roof is ten feet, the door being at one end. Perhaps in future structures, where there is plenty of earth for the back, it would be desirable to increase the width to twelve feet. Vines are planted which yield abundance of the highest-flavoured grapes, lasting from July till November, when the vines are cut, and the house is filled with geraniums, azaleas, and camellias: these give lovely flowers till advancing spring produces plenty of flowers in the open air.

"The house is lighted exclusively from the roof, and thus a maximum of light is secured with a minimum of cooling surface. From the earthen walls, the air is always kept in a proper hygroscopic condition, and as a result of the whole arrangement healthy vegetation is secured with the least possible amount of artificial heat. My house has only two three-inch hot-water pipes, and many plants may be grown 'in it without any heat. No one who loves plants and likes to see them grow should be without a Poor Man's

house; for there is no method in which so much pleasure may be obtained with so small an outlay."

Mr. Smeee seems to have a truly catholic taste, as there is scarcely a class of plants that he does not grow. Our finer British orchids, for example, we do not often find well grown in our botanic gardens, but they seem quite at home in the garden at Bedington.

"Many persons speak of Orchids as eccentric plants, to be looked upon with wonder, not with admiration; yet I must confess that, in my opinion, they are, in form and colour, the loveliest of all the lovely plants which adorn the woods and fields. Of our British orchids twenty-eight species are recorded as growing in the county of Surrey alone. A few have been found in the fields near us, and more are found on the neighbouring chalk downs. All British orchids are terrestrial, and have bulbs or quasi-bulbs. First and foremost, I grow the common orchid (*Orchis mascula*), which abounds in Kent. I procure them by digging the roots from the hedgerows in February and March, before the flowers appear. Although many have flowered in the highest perfection and have seeded every year, yet I have never known them to multiply; nor can I tell how to increase them, although they grow, blossom, and seed so well in my garden. I am always anxious to have some Bee Orchids, as a group of these plants is very beautiful. They blossom with me in the very highest perfection when grown in top-spit loam. The Fly Orchid is another lovely species, but much as I love it I never cultivate many. They grow in the very highest luxuriance in my alpines, with the curious Bee Orchis. The Man Orchis is another curious flower, but not so beautiful as the last two. It is called the Man Orchis because the flower has a resemblance to a little man dangling in the air. These grow on the southern side of our chalk downs, whence I obtained my specimens. I cultivate also the Great Butterfly Orchis, the Spotted Pale Orchis, and the common Marsh Orchis. . . .

Rustic Bridge, with surrounding Reed Vegetation, in Mr. Smeee's Garden.

"For all terrestrial orchids I use a light turf loam, which appears to suit them better than any other material. There are many other South European kinds, growing in Italy and Greece as thickly as buttercups do in our fields, which doubtless, if they were imported into this country, would readily find purchasers."

Our illustrations, for which we are indebted to the publishers of "My Garden," give a fair idea of the admirable engravings scattered abundantly throughout the book, to which we shall shortly return, and which, in the meantime, we strongly recommend to all who are interested in gardening.

THE BIRMINGHAM SATURDAY HALF-HOLIDAY
GUIDE.*

We have great pleasure in welcoming this handy and well-prepared little guide to Birmingham and its neighbourhood. The district is likely to interest many horticulturists about this time, when the horticultural wealth of the country is assembled there, and they will find the pamphlet prepared by Mr. Joseph Sturge a very useful aid. It furnishes information respecting all worth seeing within a half-day's journey of Birmingham.

FLOWER FACTORIES IN BELGIUM.

WHERE do they all come from, those innumerable multitudes of plants, which we see everywhere, indoors and out, in pots, in beds, in borders, in windows, in brackets, and jardinières, not one in a thousand of which leaves a linear descendant to continue its race, in the shape of seedling, sucker, cutting, or offset? And if such be the case with plants which, like dogs, have their day—which appear in public, gladdening the universal eye, and enjoying their allotted seasonal term—what must it be with the plants which disappear—which retire into private life and are heard of no more? Not one in a million of these would ever become a *plante mère*, a parent plant. How then is their place supplied? How many ladies per cent. get their over-year's camellias to flower, or even to live? Do not countless window gardeners grow semi-aquatics in mould as dry as brickbats, while they drench tropical succulents with water? Do they not think to get geraniums through the winter in dark closets, musty cellars, freezing garrets, and dusty corners? Is any plant so hard to kill that amateurs cannot overcome its obstinacy? In large towns and cities, the waste of plants, as of infant life, must be enormous; and yet the supply never fails short. Where do they all come from?

On popping these questions to my practical friend Hortulus, who makes a considerable consumption of the article plant, he quietly answered, "I am going to Belgium next Tuesday, to fill up my vacancies. Come with me, and see." Going and seeing being one of my weaknesses, I accepted the invitation with a jump of joy. On the appointed morning, we took the branch of the Chemin de Fer du Nord which carries wayfarers into Ghent.

There not a few of the windows attract your gaze with very respectable horticultural shows. But the streets themselves are neither crooked nor straight; they are warped to the right or to the left in such gentle curves as to baffle the possessor of the most highly-developed organ of locality. You fix the points of the compass in your mind, and resolve to reach your goal with inflexible directness. This is easy enough to do in rectilinear-streeted and rectangular-cornered towns: but in Ghent, with corners like wedges cut out of a cheese, and with streets bulging this way and that, like a whalebone walking-stick under a fat man's pressure, while making for the north you find yourself tending to the west, or desiring to become a southerner, you discover that you are one of the wise men of the east. Your only guarantee for surety is a *vigilante*.

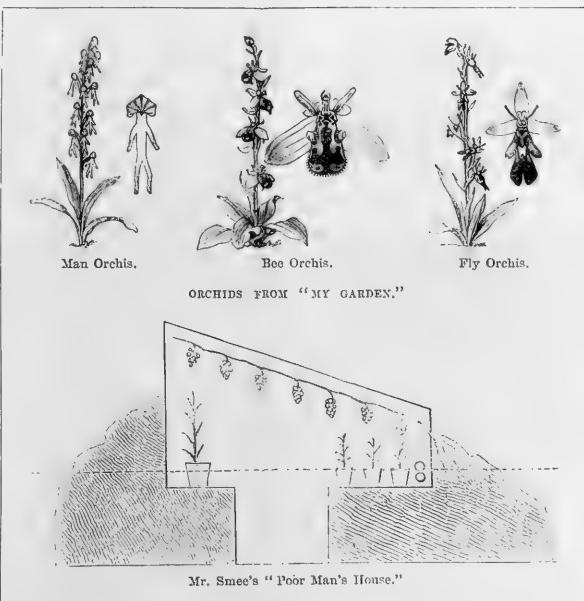

* The Birmingham Saturday Half-Holiday Guide; with a Map. Birmingham: William Walker, 21, Great Charles Street.

Hortulus, to whose guidance I have committed myself, proposes to do the little gardeners first. Of course I have only to follow my leader. In an inconspicuous lane, we enter an inconspicuous door, without name, sign or other indication of its occupant and his pursuits, and discover within a little nursery, whose specialty is azaleas and camellias. The nurseryman and his son are out, leaving the wife alone at home. Madame speaks neither French nor English, but Flemish only, which is Hebrew to us. Hortulus tries his French, in vain. I try bad German, which I have occasionally found efficacious, just as people make themselves intelligible to babies by negro talk; but in this case it proves an utter failure. Madame then rattles out her Flemish louder than before, to make me understand better, as if we were deaf; but the deafness is of the mind, and not of the ear. We are about to retire, when a hand-barrow rumbles on the stones in the lane, and stops. She seizes us by the arms to retain us, vociferously shouting "Kommen, kommen, kommen!" or some similar sound. Immediately enter the father and son, simple workmen shod with sabots. The son alone, of these three, speaks French; and the intellectual mist clears up, as as if the sun had burst through a London fog. Neither of our friends has the slightest pretensions to be master gardeners, heads of houses, or chiefs of horticultural establishments. Themselves are the only labourers they employ; consequently, they are excellently well served. They make no secret either of their management or their manipulation. As to the former, the whole surface-earth of their little plot of ground is annually thoroughly renewed with heath mould. The latter is as simple as fiddle-playing, when you are used to it. You have only to stick and fasten a little bit of this upon a little bit of the other, in such a way that it shall grow, and grow vigorously too, and the thing is done. Look! A cut or two with the knife, an opening of a cleft with a bit of blunt stick, and a binding up the wound with a ligament. That's all. If it were longer or more elaborate, how could we turn out our thousands of camellias and azaleas in the given time? There are only twelve months from the 1st of January to the 31st of December. To be sure the operation

is not everything. As bottles, after blowing, have to be annealed in heat, in ovens, so these plants, after grafting, must be *ébourfées* or stilled, under glass and in greenhouses, in an atmosphere constantly maintained in certain thermometrical and, above all, hygrometrical, conditions. But all that, like the grafting, is mere A B C, where you have been in the way of it for years.

Hortulus has long known all these details, but I have not: so he kindly gives me time to inquire. On what are the finer kinds of flowering plants grafted? Well; that depends. The common evergreen spurge-laurel, *Daphne laureola*, serves largely as a stock for the choicer and rarer species and varieties of *Daphne*. You see the seedlings in rows, established in little pots, ready to receive the slips intended to metamorphose their individuality. Young acacia plants perform a similar duty: so do those of the common laburnum. But they are not the specialty of this particular factory of flowering plants.

Cuttings of the single-flowered camellia are struck to furnish stocks for grafting the innumerable double-flowered varieties. Cuttings of the double kinds will strike not unfrequently, and with care; but they make less thrifty and handsome plants than those established

Mr. Smee's "Poor Man's House."

on the wilding stock—for such the single camellia may be assumed to be. They are also longer in becoming fit for market; which is all-important in a commercial point of view. After striking root, the camellia cuttings are potted off, to harden—such little infantile, baby-like things! Can it be possible to put a graft on such a straw-like stem as that? The question is answered by a practical affirmative. Here are some, with stems no bigger, on which a fresh graft is putting forth young leaves.

Double camellias are beautiful flowers, and the season when they come renders them so welcome; but I have a weakness for the single camellia, because years ago I saw in the royal gardens of Caserta, near Naples—may it still be continuing to flourish there—a big old bush of that species—not a tree with a stem, but a regular bush—covered with hundreds, probably thousands, of scarlet flowers. The ground around it was carpeted with red. By the way, even the fallen flowers of the single camellia render good service to bouquet-makers. They last, mounted, without fading, several days.

Indian azaleas are treated much in the same way, except that, after the graft has taken, they are planted without pots in the open ground, to be potted at the approach of autumn. The young azaleas are thus raised in rows; dutiful pupils (*élèves* they call them), who never break the ranks, nor play truant, nor disobey orders. And it is curious to see choice flowering plants considered as mere merchandise, manufactured by grafting and pricked out like cabbage plants, vegetable live-stock bred and propagated for popular consumption. Patient as little lambs do the rooted azalea cuttings wait their turn ready to receive their graft—the training which is to fit them for their future course of life.

These small special nurseries are good to visit, because they show how certain plants (which we only see in their advanced and flowering state, in shops, greenhouses, and exhibitions) are brought up from their earliest infancy. They also disclose the life-routine of a very worthy class of persons, who rarely work isolated or alone, but in small family associations or partnerships, such as father and son or sons, two or three brothers, brothers and sisters, mother and children. The month of August is the time when they expect their customers' visits, and for these they prepare during the whole previous twelvemonth. Needless to say that ready money is very acceptable, and exerts considerable influence on the terms of a bargain. For most things, the time of delivery is early autumn, when the camellia and azalea buds are well set and apparent. Speaking French, as most of them do, as a foreign language—for few visitors can answer "Yes" to their eager question, "Do you speak Flemish?"—their conversation has often a certain quaintness.

Some of these humbler horticultural establishments have their approaches and entrances so undiscernible, that you would say they intended to baffle rather than invite the intrusion of strangers. "It must be somewhere here," says Hortulus. "Last year I had difficulty in finding it, and I am not sure that I can find it now." On searching close, we discover a sort of hole-in-the-wall or open sesame trap-door, defying all but the initiated to discover and open it

"Have you got anything new this year?"

"Not much. Comme ça. Azaleas frozen in spring, comme ça. Plenty of standard laurustinus, comme ça, if you want them. Standard sweet bays, comme ça, the biggest of them gone to Russia. Never have enough of them for Russia, comme ça. Variegated-leaved plants, comme ça, the fashion; obliged to grow them comme ça, but won't last, comme ça."

"And this new-old thing?" asks Hortulus, looking at me. It was a George the Third pelargonium, a *bric-à-brac* plant, harmonising with perukes, pigtail, chintz gowns, and silk socks that will stand alone without any wearer inside to support them.

"Pelargonium tricolor, comme ça. You like it, comme ça. Have only seven plants, comme ça; must keep one, comme ça. You can take the other six, comme ça, at fifty centimes apiece, comme ça."

Another clever individual, who has been a botanical collector in his day, and knows what tropical forests are, instructs us, and at the same amuses us by pronouncing all the mute r's in his French.

"Doucement, doucément; gently over the stones. If you go so fast you won't see all the pretty things I want to show you. Here is a new fraxinelle, another species, not variety, of Dittany of Crete. I have it quite nouveauté. Like the other, the vapour around it will catch fire on a warm summer's evening. I often do it for my amusement. Those other novelties are only rubbish; they are tout bonnement, good for nothing at all. That's a nice elephant's foot (*Tamus* or *Testudinaria elephantipes*); but I am expecting some smaller and cheaper ones. You know they get them, like the zamias, by setting fire to the forests. That squat euphorbia, a green

candelabra stuck on the top of a peg-top, is at least a hundred' and fifty years old. I could let you have it for fifty francs, which makes it cost only threepence a year. But réellement I don't care to part with it, as I brought it home myself, and have taken great care of it ever since, I am fond of it, très naturellement."

Some pot or tub plants, like carriage horses, go in pairs; and the better the match, the higher the price and the greater unwillingness to separate them. Indeed, the seller will never part them; the buyer may do as he pleases, pocketing the loss and prepared for the diminished value of the divided companions. To be perfect pairs, plants must be reared as such from their earliest infancy. Like twin children, they are dressed in the same fashion, fed with the same food, washed with the same water, have their hair and nails cut on the same day and in the same degree, and are sent out of doors and put to bed at the same hour. Many pair plants have an almost indefinite term of existence—myrtles, sweet bays, cycases, dracenas, yuccas, agaves, bonaparteas, cactuses, euphorbias, tree and other ferns, laurustinus trained with a head and a stem. Consequently, the process is long, occupying years, sometimes lifetimes. The small horticulturists, with patient labour, devote daily attention to this class of nurslings, and assiduously train them in the way they should grow.

Unmatched plants belonging to this category are comparatively cheap, being sometimes to be had for half what they would fetch if paired. Their owners well know the difficulty of providing them with a mate endowed with the required compatibility of disposition. This repetition of forms in ornamental plants is called for by the architectural requirements of terraces, galleries, and greenhouses, which must have vegetable decorations, like statues and vases, alike though not exactly the same. Some positions, however, are not symmetrical, and are content with one attractive botanical specimen. Hortulus wants one *Araucaria excelsa*, to make the central figure in a group. We find a beauty in a large establishment, cheap, because single. It was either taller or shorter than the rest of its carefully coupled sisterhood; and it stood in the ranks, commanding admiration, for sale, like an unveiled beauty in an Oriental slave market. It is ours at once; entered on our list of acquisitions at the price demanded.

But there are slips between cups and lips. Next morning comes a billet-doux from the very regretful horticulteur. "Exceedingly sorry, but my brother had sold in the morning the araucaria you chose in the afternoon, without my knowing it. If you leave it to me, I will select another."

No you won't. We smell a Gantois trick. The get-off may be bosh, or it may not. Has your brother, perchance, found up for his plant an unsuspected partner on the premises? Without vouchsafing an answer, we go elsewhere. Soon after our entry, without receiving a hint, the proprietor points to a pyramidal tuft of green.

"Those are my unmatched araucarias. What am I to do with them, I don't know. I would let you have that fine fellow for five-and-twenty francs; and really it is"

"Bon! Done! We'll relieve you of that difficulty."

They say that few women marry the men they love. Few gardeners cultivate the plants they like; they are obliged to conform to horticulture de convenance, as their fair customers are compelled to make mariages de convenance. The more outspoken amongst the fraternity avow the constraint put upon their affections.

"Is it not assounant, when one really loves good plants, to be obliged to work from morning till night at producing such heaps of rubbish as this," giving the pots a contemptuous kick, "bedding-out stuff by the train-load and the milliard? One gets sick of the very sight of all these zonal, nosegays, resines, perillas, and the rest of the lot. It is for ever and ever the same balancoir, the same boutique, the same pacotille. Now and then a good new thing, or a good old thing renewed, comes in to vary our monotonous diet; but it soon either disappears, or becomes itself one of the monotones. But we must live; so we are everlasting making materials for rubans and massifs. I have a few nice things here, which I keep more for myself than the public," coaxing their leaves tenderly with the tips of his fingers; "they take at least four years to come to this; and then if I try to sell them for a franc and a half each, people scream out and call it dear. You may well call my heliotrope bushes ugly, with their crooked rough stems and their shabby straggling beds; but they have helped to make the pot boil for many a year. I sell the flowers wholesale to the bouquet-makers, and in winter they fetch remunerative prices. Ah! If I were only rich, I would still continue to be horticulteur; but then I would grow the plants that pleased me, and not be the slave of such coquetterie as this."

Another contemptuous kick at the offending bedders-out concludes the harangue. We retire, leaving the giant nurseries for inspection on another day.—*All the Year Round.*

SOCIETIES, EXHIBITIONS, &c.

ROYAL BOTANIC GARDENS, REGENT'S PARK.

(JUNE 19TH AND 20TH.)

THE near approach of the Birmingham exhibition evidently affected that which took place on this occasion, for it was very inferior to the June shows usually held in these gardens. Such plants as were shown were, however, good of their respective kinds. Amongst Orchids was a fine specimen of *Saccolabium guttatum* Hol福德ianum, with seven good flower spikes on it, and a nice plant of *Cypripedium*. Stone, one of *Stanhopea grandiflora*, and a few well-flowered examples of *Phalaenopsis grandiflora*. Stove and greenhouse plants consisted of some immense specimens, measuring as much as four feet in diameter. Amongst them were some good Allamandas, large plants of *Erica ventricosa coccinea* and Cavendishii, and a few examples of *Phoenicocoma proliferum* in good condition. Mr. Baines's *Ixora coccinea* is still in wonderful beauty; it had flower-heads fully eight or nine inches through. The same exhibitor also showed a nice plant of *Roella ciliata*. Heaths were at their best, especially E. Cavendishii, which was literally loaded with bloom. Pelargoniums formed one of the principal features of the show; amongst them were immense specimens from Mr. Ward, measuring fully four feet through, and densely bloomed. Fancy Pelargoniums were also profusely flowered. Mr. Turner's group of twenty included many of exquisite form, and purity of colour; one called Purple Gem was one of the finest dark kinds we have seen. Pompey, Imperator, and Princess Royal were in great perfection. A zonal Pelargonium from Mr. Wm. Paul, called Wellington, had very large trusses of flowers, and is apparently a fine bloomer. Some good collections of hardy herbaceous plants were exhibited both in pots and in a cut state. Where they were arranged in broad, circular, shallow baskets, some attempt was made to heighten the effect by hiding the pots with moss, and overlapping the edges of the baskets with hardy fern fronds. Of Irises, Pyrethrums, and Pansies, some fine examples were exhibited, as were likewise a few very pretty Ranunculus, Diathus, and Pinks. There was only one competitor in the class for Roses—Messrs. Paul & Son of Cheshunt, who produced fine healthy plants in pots which, considering that Roses in pots are now almost past, were very excellent. The same exhibitors contributed a large collection of cut blooms of Rosacean Peonies. A group of plants from Messrs. E. G. Henderson & Son was tastefully arranged, and consisted of some very good new and fine foliaged plants. At the back was a plant of *Encephalartos villosus* with fine broad fronds, around which were arranged several of the finer and more graceful Palms, Dracemas, Rhopalas, a plant of the curious *Amorphophalus Rivieri*, and a good specimen of the staghorn fern. Intermixed with these were a few flowering Calceolarias and *Anthurium Scherzerianum*. The front was edged with *Echeveria secunda glauca*; then a row of a silver tricolor Pelargonium, inside of which and between the graceful foliaged plants at the back were small boxes containing some fine Coleus, Petunias, the beautiful dwarf Maidenhair Thalictrum, variegated Cypress, and others. In the same collection were also some fine new Begonias, especially one called rubra superba, to which a first-class certificate was awarded; its lovely deep crimson flowers are shaded with violet, and resemble the Boliviensis type. In the nurserymen's collection were some good plants, such as a remarkably well-grown plant of *Sarracenia californica*, from Mr. B. S. Williams, the lovely rose-spotted *Bertolonia superba* and *Alocasia illustris*, from Mr. Bull; a fine group of ornamental foliage plants and stands of splendid Pansies from Messrs. Downie, Laird, and Laing, and a box of cut blooms of bulbous plants in the form of *Ixias*, *Tritonias*, *Antholyzas*, &c., from Messrs. Hooper & Co. of Covent Garden.

First-class certificates were awarded to *Rhopala granatensis*, *Pteris Applebyana*, and *Agave Regeliana*, from Mr. B. S. Williams. A first-class certificate was likewise conferred on *Rose Annie Laxton*, from Messrs. Paul & Son; to *Begonia rubra superba*, and tricolor Pelargoniums Alice Mand Mary, and Meteor, and also to *Verbena Harry George Henderson*, from Messrs. E. G. Henderson & Son. Similar awards were also given to Pelargonium Charles Dickens, from Mr. C. Turner; to P. Purple Gem, from Mr. Foster; to P. Captain Raikes, from Mr. Weatherill, Finchley; and to Petunia King of Crimsons (a good double one), from Messrs. Dixon & Co., Moorgate Street.

ROYAL HORTICULTURAL SOCIETY'S EXHIBITION AT SOUTH KENSINGTON.

(JUNE 19TH.)

THIS, like that at Regent's Park, was by no means an important show. Its chief features were two miscellaneous collections of plants exhibited by Messrs. William Rollinson & Sons and Mr. B. S. Williams. Baskets of plants arranged for effect were also good, and Pains were pretty well represented, the first-prize collection of them being furnished by Mr. B. S. Williams. It consisted of fine specimens of *Chamaecaris humilis*, *C. Fortunei*, *Thrinax elegans*, *Corypha australis*, *Phoenicophoruma Seychellarum*, *Sabal Blackiana*, *Latania*, *coronaria*, and *Calamus asperifolia*. Cut blooms of Ranunculus were likewise pretty well shown. For Fuchsias, Mr. Wright, of Lee, Kent, was awarded the first prize in the nurserymen class, with the following kinds, viz.: Starlight, Excelsior, Mrs. Marshall, Gipsy Queen, Conspicua, and Imitable. The competition in the non-variegated Pelargonium classes was not great, but the group shown by Mr. J. Cathlin, gardener to Mrs. Lermitté, of Finchley, was

in all respects good, each of them being about four feet across, and well-flowered. Among these the best plants were the following: Lord Derby, (bright scarlet), Rosa Rendalter, Virgo Marie (white), and Pioneer (salmon). For a basket of plants arranged for effect, only four competed, and among these the best was that of Mr. J. Hepper, gardener to C. O. Ledward, Esq. It contained a dark leaved Dracaena in the centre, surrounded by plants of *Caladium*, *Coleus*, *Cockscombs*, *Bambusa Fortunei variegata*, Maidenhair ferns, and variegated *Aspidistra*, the dying consisting of variegated Honeysuckle, *Dactylis*, Blue Lobelia, and variegated *Panicum*, intermixed. *Campanula dichotoma*, said to be a new annual species, was shown in good condition by Mr. Mackintosh, and Mr. Barr showed several distinct varieties of *Lilium bulbiferum*. From G. F. Wilson, Esq., Webyridge Heath, came *Lilium californicum*, with glorious crimson-tipped and spotted flowers; from Mr. Green, gardener to Wilson Saunders, Esq., a hybrid *Streptocarpus*, between Rexia and Saundersii, with lilac flowers. Mr. Denning, Grimstone Park, sent a magnificent group of Orchids, for which he received a cultural commendation, also a fine specimen of *Epidendrum nemorale*. From Mr. Wilson, gardener to W. Marshall, Esq., Enfield, came *Phaius Marshalliae*, with large pure white and yellow flowers. This received a first-class certificate. Mr. Stott, Alnwick, sent enormous stalks of Rhubarb; Messrs. Sutton, a plant of their remarkably fine new pea "Best of All," the consideration of which was adjourned to the meeting at Chiswick, where this variety is at present growing in the collection.

First-class certificates were awarded to Mr. Williams, for *Pteris Applebyana*, one of the most gracefully-crested ferns we have ever seen; to Mr. Edmonds, for golden tricolor Pelargonium Mrs. H. Little; to Mr. Welch, for golden tricolor Pelargonium Magdalæ; to Messrs. Downie, Laird, and Laing, for Pansies Mrs. Neilson, James Neilson, Lady Ross, and Miss McKen; and to Mr. Cripps, for *Cupressus Lawsoniana lutea*.

ROYAL HORTICULTURAL SOCIETY'S BIRMINGHAM SHOW.

THE following memoranda may be useful to such as intend being present at this great floral festa:—

Excursion trains will run as under:—

The London and North-Western Railway Company from London to Birmingham, on Saturday, June 22nd, returning on Thursday, June 27th.

From all principal Northern stations in Lancashire, Cheshire, and Yorkshire, on Monday June 24th, returning on Friday, June 25th.

On Thursday, June 27th (One Shilling day), day trips from Northampton, Blisworth, Weedon, Rugby, Stamford, Market Harborough, Leicestershire, Nuneaton, Coventry, Lichfield, Kidderminster, Worcester, and Lichfield.

On Friday, June 28th (One Shilling day), day trips from Liverpool, Warrington, Herford, Crewe, Manchester, Stockport, Alderley, Chester, Beeston Castle, Shrewsbury, Wellington, Newport, Stafford, &c.

On Saturday, June 29th (Sixpenny day), day trips as follows:—

By the Great Western Railway Company, on Thursday, June 27th (One Shilling day), from Shrewsbury, calling at principal intermediate stations to Albrighton, in Shropshire; Leominster, Warwick, Kingswood, and Knowle; from Worcester, Bromsgrove, Evesham, Alcester, Redditch, Droitwich, Kidderminster, and Stourbridge.

On Friday, June 28th (One Shilling day), from Oxford, and all intermediate stations, to Harbury inclusive.

On Saturday, June 29th (Sixpenny day), from Worcester, Droitwich, Kidderminster, and Stourbridge; from Leominster, Warwick, Kingswood, and Knowle, to Hereford, and thence to Gloucester, Cheltenham, Tewkesbury, Worcester, Shifield, Chesterfield, Belper, Manchester, Burton, Bakewell, Matlock, Lincoln, Newark, Nottingham, Derby, Burton, Tamworth, Peterborough, Stamford, Oakham, Melton, Bedford, Wellingborough, Kettering, Market Harborough, Leicester, Hinckley, Nuneaton.

By the North Midland Railway Company:—An excursion train from the station on Thursday, June 27th.

The particulars of dates, times, and fares, will be set forth by the several companies in advertisements and bills, in course of issue.

Ordinary return tickets to Birmingham, issued by either of above-named companies, on Saturday, June 22nd, and following days, will be available for returning on any day up to and including Monday, July 1st.

Exhibitors and others desiring private lodgings near the show ground should communicate at once with Mr. Quilter, Lower Grounds, Aston, Birmingham, enclosing stamped directed envelope for reply. Mr. Quilter keeps a register of houses in the neighbourhood where apartments can be had.

Exhibitors who require horses to convey their vans to the show grounds should at once communicate with one of the under-named according to the line they will use, stating on which day and by what train they will travel, and whether they will want one horse or more. If by the London and North-Western, to Mr. Nicholls, London and North-Western Railway, Curzon Street, Birmingham; if by the Midland, to Mr. Pearson, New Street station, Birmingham; if by Great Western, to Mr. G. W. Andrews, Snow Hill station, Birmingham. If vans as well as horses should be required it must be stated, and some idea of size given. Exhibitors who take only a few boxes with them will find it cheapest to hire vans or carts to convey them to the Lower Grounds. The fare for the former is 2s., for the latter 3s.

The local committee have arranged for many of the leading manufacturers in Birmingham and the district to be opened for inspection, free of charge, on production of an introduction from the local hon. sec., Mr. E. W. Badger, who will be on the ground all the days of the show. A complete list of these manufactories will be issued in the official catalogue.

NOTICE.

The FIRST VOLUME of THE GARDEN will be Published early in July, accompanied by an Original Portrait of the late Mr. London, a memoir of whose life, by his friend, Noel Humphreys, will be commenced in our next number.

The Name and Address of the writer are required with every communication, though not for publication, unless desired. Letters or inquiries from anonymous correspondents will not be inserted. Correspondents, in sending queries or communications of any kind, are requested to write on one side of the paper only.

All communications for the Editorial Department should be addressed to WILLIAM ROBINSON, "THE GARDEN" OFFICE, 37, Southampton Street, Covent Garden, London, W.C. All letters referring to Subscriptions, Advertisements, and other business matters, should be addressed to THE PUBLISHER, at the same Address.

Readers who may find it difficult to procure THE GARDEN regularly through the newsagents, may have the numbers sent direct from the office, at 19s. 6d. per annum, 9s. 9d. for six months, or 5s. for a quarter, payable in advance. All the back numbers may be obtained. THE GARDEN can be had in neatly covered monthly parts. On sale at Messrs. Smith & Son's bookstalls, and may be had through all booksellers. Part VI. for May, now ready, price 1s. 5d.

PROPER SEASON FOR SOWING THE FOLLOWING.

E. G. HENDERSON & SON

Offer the following in superfine strains. For Winter bloom and growth, PRIMULA, CINERARIA, and CALCEOLARIA should be sown immediately. For Spring bloom, sow throughout July.

Primula sinensis	fimbriata	alba, elegantly fringed	s. d.	
Ditto	rubra	ditto	2	6
Ditto	magnum	bonum, richest colour	2	6
Ditto	Mixed colours	...	2	6
Ditto	Filifolia rubra	beautiful	2	6
Ditto	Fern-leaved	...	2	6
Ditto	Ditto	alba ditto	2	6
Ditto	Ditto	mixed colours, do.	2	6
Cineraria, finest quality in mixed colours	...	2	6	
Calceolaria, Herbaceous, large flowered, splendid varieties	...	2	6	
Cyclamen persicum, an assortment in six varieties	...	4	0	
Ditto	Choice mixed (from thirty beautiful varieties)	is & 2 6		
Ditto	An assortment of twelve (species and varieties)	7	6	
Clove Carnations, fine strain in mixed colours	...	2	6	
Carnations, mixed colours, also in yellow ground colours	...	2	6	
Ditto	perpetual or winter-flowering, mixed colours	2	6	
Ditto	picotee section, fine mixed colours	2	6	
Humea elegans	...	6d & 1 0		
H. elegans purpurea, new	1s & 2 6		
Hollyhocks, twelve first-class varieties	...	4	0	
Ditto	Various colours mixed	1s & 2 6		
Pansies, assortment of eight bedding kinds	...	2	6	
Ditto	colours separately, 6d each			

E. G. HENDERSON & SON

Also offer established young seedling plants of PRIMULA JAPONICA, the "Queen of Primroses" one of the finest plants ever introduced to English gardens; stately in its growth, beautiful in variety of colour, and perfectly hardy. A selection of Six varieties, including distinct colours of Red, White, White mottled with Red, Mauve with red centre, rich dark Crimson, and Pink.

3s. 6d. each. In Larger Quantities, Special Prices.

Seed also supplied at 2s. 6d. per packet. Should be kept in a cold frame or pit, and will not germinate freely until twelve months after. For descriptive notes on the above see

E. G. HENDERSON & SON'S DESCRIPTIVE CATALOGUE OF SEEDS,

WELLINGTON NURSERY, ST. JOHN'S WOOD,
LONDON, N.W.

WANTED, a GARDENER, in the country, forty miles from London, to take charge of a rectory garden—flower and kitchen—which should be especially suited to a resident family, to be capable of being worked on the premises, and thoroughly trustworthy. State wages and all particulars.—Address, A. B. C., Post-office, Baldock.

GARDENER (HEAD).—Age 27; married; thoroughly understands the management of vines, peaches, nectarines, cucumbers, melons, &c.; also thoroughly understands flower and kitchen gardening; competent to undertake all the duties of head gardener; three years ten months' good character.—Address, D. H., Coval Terrace, Chelmsford, Essex.

UNDER ROYAL PATRONAGE.

THE ROYAL POTTERY, WESTON-SUPER-MARE.

JOHN MATTHEWS (late C. PHILLIPS), Manufacturer of Terra-Cotta Vases, Fountains, Italian Baskets, Rustic Floral Arboreta, Statuary, Garden Foss (from two to thirty inches in length), Glazed and Unglazed, and Glass Frost, and no become Green, Edging Tiles, &c., &c. See Specimens at the Royal Horticultural Society's Show. Price List Free. Book of Drawings, 6d. each.

Vases during winter.

WORKS AT Nos. 360 to 375, BOSTON ROAD, NEAR

THE REGENT'S PARK.

Price One Shilling.

A CATALOGUE OF CULTIVATED HARDY PERENNIALS, BULBS, ANNUALS, &c., including also all British plants. Prepared for the purpose of facilitating exchanges, &c., and enumerating nearly 10,000 hardy exotic and British plants. Post free from "The Garden" Office.

GARDEN

"This is an art

Which does mend nature : change it rather : but
THE ART ITSELF IS NATURE."—Shakespeare.

NOTICE.

The FIRST VOLUME of THE GARDEN will be Published early in July, and will contain an Original Portrait of the late Mr. Loudon, a memoir of whose life, by his friend, Noel Humphreys, is commenced in the present number.

RECOLLECTIONS OF JOHN CLAUDIUS LOUDON.

BY NOEL HUMPHREYS.

The name and works of John Claudius Loudon are destined to mark an epoch in the annals of British horticulture, as one in which a new and more vigorous life was breathed into it. No single mind and hand ever tugged so laboriously and successfully at the chariot of progress in that important section of human art as those of the man whose career forms the subject of this too imperfect memoir. The hearty toil in the cause which he made the main and almost sole business of his life was uncasing. To him, however, neither the mental or bodily wear and tear of such unceasing labour formed any real trial or trouble. He thoroughly enjoyed both; and, as Goethe said of the motions of the stars, "without haste, and without rest" ("ohne hast, ohne rast"), he steadfastly pursued the noble task he had set himself, in spite of all opposing difficulties, to the very last. Unlike most of his northern countrymen he did not possess the sinewy frame of the hardy sons of Scotland. His muscular development was comparatively feeble, and one arm was, at an early period of his career, irretrievably crippled by an unfortunate accident. But the mind was a vigorous one, and remained so to the last. He died, so to say, in harness, and almost in the act of dictating matter to his amanuensis. His death, in fact, took place standing on his feet, for when a sudden change was seen to take place in his countenance, and he was laid upon a couch, it was seen that life was already extinct, and that he had, in fact, died standing.

I had not the privilege of knowing Mr. Loudon till the later part of his career, but after his marriage (with a family connection of my mother's) I saw him very constantly, and was thus enabled to form a just estimate of one of the most high-minded and generally capable men I ever knew. His keen intellect was entirely unshackled by prejudices of any kind, and his liberalism had consequently the true ring of the bright pure metal of advanced thought. But his truly humane, charitable, and kindly disposition made him ever tolerant of the opinions of others less advanced than himself; for however harshly or inverterately obsolete dogmas were urged in his presence, he never retorted in a similar strain, and was always open to conviction when matter was adduced which he had not before appreciated at its just value.

I have gathered the following facts connected with his early career partly from his own recollections, which he often communicated to me in long after-dinner talks (in which he was always a charming interlocutor), and partly from the short memoir which his late widow drew up and printed for private circulation shortly after his death.

John Claudius Loudon was born on the 8th of April 1783, at Cambuslang, Lanarkshire, at the residence of his mother's only sister, whose son, Dr. Claudius Buchanan, is well known in connection with his earnest endeavours to convert and instruct the Hindoos. John Claudius, the subject of the present memoir, was the eldest of a numerous family. His father, a successful farmer, resided at Kerse Hall, near Gogar, a few miles from Edinburgh. He was a man of superior

natural intelligence and considerable information; and perceiving the unmistakable aptitude of his son John for acquiring knowledge, determined that he should have every possible advantage in his education. One great deficiency, however, existed—John Claudius took no delight in the acquirement of languages. To Latin and Greek he had an insuperable aversion; and even the study of the modern tongues was exceedingly irksome to him. This was a great discouragement to his parents; but his father, being very anxious that he should at all events know French well, had a master over from Edinburgh for the express purpose of teaching him that language; but the result was extremely unsuccessful. The recalcitrant pupil deeply regretted in after life his obstinate opposition to such studies during his early years; and in speaking to me on the subject, remarked, on more than one occasion, that he thought it was his impatient greed for abstract knowledge which made him so averse to spending his time in the study of any dialect in which such knowledge happened to have been originally given to the world. He used to say it was his idea, as a boy, that "all the best works of all time and all countries had been well translated into the English tongue, and that he then felt that while labouring to acquire even an imperfect knowledge of the language of a single country, he could, and did, absorb the cream and substance of the literature of many."

In addition to his deeply-indulged passion for general reading, a natural taste for landscape gardening began to show itself at a very early period, and he occupied most of his leisure in planning miniature walks and beds in a small piece of ground which his father had given to him for a garden. So keen was his early enthusiasm to obtain seeds, out of the usual routine, to sow in it, that he made many childish sacrifices in order to gratify his anxious wishes in that direction. On one occasion, when a jar of tamarinds arrived from an uncle in the West Indies, he gave the other children the whole of his share of the fruit, on condition that he should have *all* the seeds. He was very fond of telling the story of the tamarind seeds in his after life, and sometimes with a sly and humorous object in view. I recollect that on a special occasion, after one of the pleasant dinners in Porchester Terrace, on a particular day, when a small specimen plate of a fine new cherry was the chief attraction of the dessert, that Mr. Loudon introduced the subject of his early enthusiasm for gardening, by telling the tamarind story. Mr. Repton, the son (or nephew) of the well-known landscape gardener, was present, who immediately boasted of quite a kindred enthusiasm in the same cause; upon which Mr. Loudon laughingly *cornered* him, as the Americans have it, by demanding the four delicious cherries on Mr. Repton's plate, promising him faithfully that he should have the stones to plant in his garden. His little sallies of this kind were always highly relished, as my genial old friend did not generally go in for the part of "funny man," and was no friend to practical joking of any kind.

While yet a youth in point of years, he was sent to reside with an uncle in Edinburgh, in order that he might be made to attend regularly the classes at the public school, and possibly be induced by the force of emulation to attend to those studies which had hitherto repelled him, especially the acquirement of languages. The desired effect was to some extent produced. He overcame his prejudice against the utility of Latin, in which he soon made good progress, as well as in arithmetic and drawing. He also regularly attended lectures on botany and chemistry, making copious notes, illustrated by spirited pen-and-ink sketches, which were still in existence at the time I knew him. He was induced to study French at the same period, that is to say, when he was about fourteen, by a little occurrence which I have often heard him describe. His uncle, being an amateur of fine prints, was one day showing a remarkable engraving to a friend, and the title being in French, he called upon his nephew to translate it for them. This he was unable to do; and the boyish mortification which he felt on that occasion, the bitterness of which he never forgot, as he used to tell, made him determine to use every effort to acquire the French language. After that resolution he did so; in a comparatively short time paying his master himself

out of money which he received for a translation from the French made for a periodical. In order to keep up his practice in the newly-acquired tongue, he resolved to keep his journal (which he commenced at thirteen and continued regularly for thirty years) in that language. He also studied Italian with some success at the same period. But although he thus got over his earlier feeling with regard to "the loss of time" incurred in learning languages, the studies he took most delight in, were the acquisition of a fine handwriting and the drawing of landscape. So great was the proficiency he acquired in the first named of these studies, that his master, Mr. Paton, whose daughter became so famous as a singer, prophesied, in a complimentary letter to his father, that Master John would become one of the best caligraphers and, at the same time, most rapid writers of the day. He was, however, not destined to produce the greater portion of his voluminous works by the manual use of his own pen; for, in consequence of the accident to his arm, and the crippling effects of rheumatism at a comparatively early age, he was ever afterwards compelled to employ an amanuensis.

Landscape drawing was, above all others, his favourite pursuit; and when his father, after some opposition, consented to his wish of being brought up as a landscape gardener, he found himself fully competent to take the situation of draughtsman and assistant to Mr. John Mawer, at Easter Dalry, near Edinburgh. While in his employ young Loudon acquired a good deal of useful knowledge of gardening generally, particularly of the management of hothouses, on which subject he afterwards wrote a special work. He subsequently resided for a time with Mr. Dickson, who was a well-known planner (as landscape gardeners were then called in Scotland), and who had an extensive nursery in Leith Walk, where his pupil acquired an excellent and extensive knowledge of plants. During his stay with Mr. Dickson, with whose family he boarded, he pursued his studies with a degree of diligence and determination seldom equalled. He sat up studying and writing two entire nights in each week, keeping himself awake with green tea; a habit he continued for several years. The extent of information which he then stored up for future use was enormous, and fully accounts for his being able in his after career to join with distinction in the discussion of a vast range of scientific subjects, often to the considerable astonishment of his hearers, who did not expect to find in a modest young landscape gardener, such a fund of knowledge and anecdote upon nearly every subject likely to arise in general conversation. Let ambitious young horticulturists who may despise the patient and persevering labour by which he acquired the fund of information which eventually made him famous, be convinced that, however great their talents may be, there is no short cut to such a career of usefulness, and such lasting fame, as was achieved by the laborious industry which distinguished the youth of John Claudius Loudon.

While with Mr. Dickson he continued to attend botanical classes and lectures on chemistry, while he commenced at the same time a serious study of the principles of agriculture under Dr. Carpenter, Professor of Agriculture in the University of Edinburgh, who always considered him his most promising pupil.

In 1803 he first arrived in London, and on the day after his arrival, as recorded in his carefully-kept journal, he called on Mr. Sowerby, of Mead Place, Lambeth, where he was, as expressed in a passage in his journal, "exceedingly delighted with the classification and arrangement of the mineralogical specimens." These appear to have made a strong impression upon him, and to have gratified him the more especially as being in accordance with his own instinctive love of order, the effects of which he had never before seen so well exemplified as in the collection of specimens which he had thus the opportunity of examining. He afterwards devised a similar plan for use in his own books, but much more complete in many respects, and which he first made some use of, several years afterwards, in his celebrated "Encyclopaedia of Gardening."

He brought from Scotland a number of useful, and indeed important, letters of introduction, with which the keen-sighted prudence of his Scottish father had furnished him. These were principally to noblemen and gentlemen of landed property, many of them being from Dr. Carpenter; but there was one,

more important than all the rest, which at once opened up to him the *entrée* of the most distinguished literary and scientific circles of London: it was to Sir Joseph Banks, who at once appreciated the acquirements and energy of the young Scotchman, and introduced him to many of the eminent men of the age. The effect produced on the mind of the ambitious young student by the society and conversation of some of those eminent scientific men was at once most sudden and striking, as evidenced by the brief passages in his journal, in which he records his first impressions of the scientific world of London. From Sir Joseph Banks, the great naturalist; from Laurence, the daring young surgeon-anatomist; from the large-minded Jeremy Bentham, the theoretic politician, who was destined to furnish drafts of free constitutions to so many new States, as in rapid succession they shook off the withering coil and cumbersome trammels of old-world despotisms, young Loudon greedily imbibed those enlarged political and social sentiments which all who knew him intimately so much admired; and in his case they were ever tempered by a benevolence and general softness of manner and feeling which endowed his conversation, even when expressing his advocacy of the most sweeping and thorough-going progress, with an indefinable charm that seduced even the opponents of his theories; though many of them, no doubt, deemed them wildly extravagant.

But while plunging into the fascinating vortex of scientific society, he was, at the same time, like a prudent Scotsman, taking care of the "main chance"; and soon became, by his assiduity and conspicuous knowledge, very extensively and lucrative employed in landscape gardening, though he was then only in his one-and-twentieth year. He thoroughly enjoyed this full swing of a profession which he had adopted entirely from his own strong predilection. But yet there were drawbacks to his enjoyment, which, as a young man, full of youthful enthusiasm, he had not foreseen. His plans were always greatly admired, but often deemed either too costly or too impracticable, or involving changes and innovations of a too sweeping character; and it thus frequently became necessary to give in to narrow or ignorant views of this kind, to the utter destruction, perhaps, of some of the best points of a largely-conceived and well-digested plan. But what was much more difficult to bear patiently was, that in very many cases, the great completing features of his designs, which he had not been allowed to carry into effect, were afterwards executed by others; who thus obtained the credit of his design, and utterly ignored their indebtedness to the original contriver. When such encroachments upon the répute which was justly his due, occurred, he was frequently urged to assert his prior claim; but he always answered, in that truly liberal spirit which distinguished him throughout his whole career, that the person who actually made an invention useful, either to a private individual or to the public, had more merit, and deserved more praise, than the original inventor who had never carried it out.

(To be continued.)

THE ROSES OF PUTEAUX.

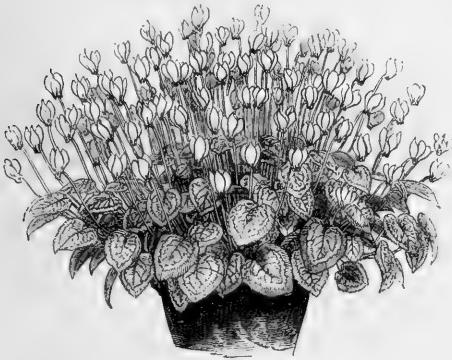

It is from the vast fields of rose trees at Puteaux that the perfumers of Paris obtain the necessary supply of roses. Little by little these fields have diminished, and at last to such an extent, that those interested in obtaining the flowers deemed it time to inquire the cause. The result of this inquiry is, that the cultivation of roses at Puteaux threatens to be abandoned, for three reasons. In the first place because the land is sold for building villas with gardens; secondly, because the roses are no longer sufficiently remunerative; thirdly, because the severe frosts of last winter destroyed the greater part of the plantations. A representative of the Paris perfumers asked the cultivators to name the price which would remunerate them for the cultivation of the roses; they replied, "If we receive one hundred francs (four pounds sterling) per hundred kilos., we will replant our fields." The conditions were accepted by the perfumers, and these rose fields are to bloom again as of old. At Adrianoport, the rose fields extend over some 12,000 or 14,000 acres. The season for picking the roses is from the latter part of April to the beginning of June, and at sunrise the plains look like a vast garden full of life and fragrance, with hundreds of Bulgarian boys and girls gathering the blooms into baskets and sacks. These rose fields generally produce abundant crops, and constitute the most important source of wealth in the district.

THE INDOOR GARDEN.

CULTURE OF CYCLAMENS.

BY H. LITTLE, CAMBRIDGE VILLA, TWICKENHAM.

The article which you published (see p. 501) describing Mr. Wiggins's method of cultivating Cyclamens is an admirable one, and I cannot, I fear, add much to it; still, as you have done me the honour of having a representation made of one of my plants, I must have a few words to say on the subject. My aim is to produce flowers of rich and distinct colours, with good shape and substance, good foliage, and especially plants with a good habit. I cross only my very choicest varieties on the above principles, and recommend not more than three or four blooms for seed on each plant, and for this reason, each bloom when crossed will produce, putting aside accident, a pod containing from thirty to sixty or more seeds; and as each pod grows, if well attended to, to the size of a large hazel-nut, I am sure that if too many pods are produced by a bulb, it will either die or give scarcely any bloom the following season. I cross each bloom carefully, if I want colour, with two blooms of separate plants of the best colour and shape I can find, and so with each, for I find you can vary the flower very much; and I hope to see Cyclamens produced with striped and edged petals, or with spotted flowers. The seed ripens in July and

Cyclamen persicum, grown by Mr. Little.

August. I sow in September in pots in a light fibrous soil, with a little leaf mould and sharp sand, well drained. When the seedlings are fit to handle, I prick out about ten or twelve in a forty-eight-sized pot, in similar soil. When large enough, I pot singly in small sixty-sized pots, and repot when these are full of roots. For the last potting prior to blooming, I use stiffer soil—some leaf mould, sand, and some well-decayed manure (be careful to see there are no grubs or worms in this, and give plenty of drainage).

While growing during the summer, the foliage must be kept very clean and well-sprayed. When in bloom do without fire-heat as much as possible, giving air on all occasions when free from frost or rain. I cannot too strongly insist on the absolute necessity of keeping the plants in all their stages of growth and bloom free from green fly or red spider. Stop them at once, and do not leave off till all traces of them are removed; for if allowed to gain head, the beauty of the plant will be completely spoilt. The bloom will become crippled, and the foliage shrivelled and unhealthy.

I can scarcely praise the value of Cyclamens too much; for whilst growing, and previous to blooming, they are splendid foliage plants; and in this stage, as well as when in bloom, they are admirable for table decoration. They commence blooming in September and October, and continue, if not forced in heat, until April and May. They could be

exhibited in December; but in February and March I think they could be shown in perfection, the colours being then true and fresh, and the foliage firm and good. Later on, the sun affects them, and softens both foliage and flower. I like to see them without sticks, ties, or supports of any kind; nothing can be more graceful when well grown and of good habit.

The bulbs should be carefully watered and well ripened after blooming, as I think next season's display depends on this. They should not be shaken out or repotted, I consider, until they break, when they should be carefully cleared of decayed stalks, and potted into smaller pots than those in which they last bloomed, shifting them into larger ones as they require it.

WINTER FLOWERS.

It may seem somewhat anomalous to write about winter flowers in June, but now is the time to push on vigorously young stock of such soft-wooded plants as Begonias, Justicias, Gesneras, Eranthemums, Thysanocanthus rutitanus, Centradenia, Libonias, Poinsettias, and other plants of that kind. Low close pits are just the places for bringing on rapidly young plants for autumn and winter flowering; the great thing being to get the growth made and ripened before short days come upon us. Cuttings of most of the things I have named struck in March, will make nice flowering plants in one season in six and eight inch pots. After flowering the best plan is to reserve two or three plants of each kind (according to the amount of stock required) to produce cuttings, and to throw the remainder away; except, of course, Gesneras, which are bulbous-rooted. Young plants, if the growth has been well ripened, will flower more profusely than old ones, and, what is perhaps of equal importance, they will last longer in a low temperature. Amongst Begonias for winter flowering, insignis and fuchsoides are two of the most useful for the conservatory. I admit that neither of them are new; but plants of insignis especially do well in a cool house if moderately near the glass. I have grown them by the hundreds from cuttings in early spring; and potted on into six-inch pots they make elegant dinner-table plants; or if a large vase has to be filled, four or five young plants of it well furnished with branches will do it beautifully, and will remain in good condition for a considerable time. Begonia Weltonensis for summer and autumn blooming deserves to be largely grown.

Thysanocanthus rutitanus is one of the most elegant plants for winter decoration with which I am acquainted. It may be grown, too, so as to have nice blooming plants from cuttings in one season; and its long wreaths of brilliant crimson flowers hanging gracefully down in all directions in winter for months at a time have a very telling effect. It is one of the easiest of plants to grow and propagate; it is subject to no disease, and insects seldom attack it. It may, in fact, be grown with as much ease and certainty of flowering as a Tom Thumb geranium. Turfy loam, with a dash of leaf-mould in it, suits it perfectly. Justicia speciosa is another most useful plant, of which good-sized bushes may be grown in one season. It blooms very profusely in winter. Hebeclinium ianthinum is also a grand winter and early spring flowering plant for a cool stove or intermediate house, to be moved when in bloom to the conservatory. Under liberal treatment it may be grown quickly into a large specimen, and its large clusters of Ageratum-like flowers, which remain in perfection for a long time, are very effective. It does best in peat and loam, enriched, for the last shift, with a little two-year-old manure and a sprinkling of silver sand. Libonia floribunda blooms in January, just before Hyacinths and other Dutch bulbs come in full force; but to induce it to flower freely, the growth must be made early, and afterwards well ripened by exposure to the air.

Manettia bicolor is not so common in stoves as it was twenty years ago. It is a very pretty creeping plant, of slender habit, well adapted for basket-work or for covering low screens. It is easily cultivated; in peat and loam, with silver sand, it does admirably. It should be grown rapidly in early summer, and afterwards, if possible, placed near the glass to ripen its growth; if treated thus, it will be completely covered in winter with its very pretty crimson and yellow flowers. Long pieces of it are very pretty for mixing with flowers and foliage in tall glasses for the drawing-room.

This list might be much extended, and where flowers are in large demand in winter, many old-fashioned stove-flowering plants that have been discarded for the more fashionable foliaged plants, might be grown in the way indicated in large numbers, either for the conservatory or for drawing-room stands.

E. HOBDAY.

NOTES OF THE WEEK.

— It may interest some to know that a list of localities of plants growing in Hertfordshire has just been published by the Rev. R. H. Webb. It shows a considerable increase in the way of discoveries of localities of now plants.

— VINE MILDEW, it is stated, has ruined a fourth part of this season's grapes in the colony of Victoria. The mischief has been effected by the true Oidium Tuckeri, which is thought to have been imported on vine cuttings brought from France or Spain.

— At Mr. Bunney's sale of Orchids the other day £14. 10s. was paid for what is called Bunney's variety of *Saccolabium guttatum giganteum*. The plant is described as having nineteen leaves on it and one "break." The total amount of the sale, which consisted of 590 lots, was between £500 and £600.

— SEVERAL hundreds of market-garden labourers at Fulham, and other south-western districts, are still on strike, although acres of strawberries are said to be rotting on the ground for want of gathering. Fresh hands are, however, being gradually introduced, and placards are freely posted warning workmen in the disaffected districts against intimidation or violence.

— SEVERAL plants, not commonly grown against walls, are now flowering on the boundary wall of the herbaceous department at Kew. Among them may be named *Solanum jasminoides*, a free and very showy blooming plant; the shrubby scarlet-berry bearing *S. pseudo-capicium*; and *Habrothamnus corymbosus*. The last, which is usually kept under glass, has lived planted out here throughout several winters.

— THE *Pharmaceutical Journal* learns from Ceylon that, in consequence of the higher price realised in the home market for the bark of *Cinchona officinalis* over that of *C. succirubra*, considerably more attention is now being given to the cultivation of the former species. A single firm in the island, whose exportation of *C. officinalis* realised in England as much as 3s. 3d. per pound for unassorted bark, has applied to the Government plantations for as many as 350,000 plants.

— A FLOWER SHOW was held the other evening in the grounds of Mr. E. W. Winterbotham, Bank House, Strand. The exhibitors were confined to the children attending Bedford Street Sunday schools, and prizes of small amounts were offered for various classes of window plants, wild flowers, &c. There was a considerable and really meritorious collection, capitally arranged in a shady avenue, and it attracted to the spot a large number of friends and other visitors. A band of music added to the gaiety of the scene.

— FRANCE south and west, down to the shores of the Mediterranean, may almost be called one vast vineyard. For several years the vine in these districts has been affected with mildew (Oidium). A remedy for this, however, was found, and the evil has been partially removed. Now, however, a new blight of a much more fatal character, the phylloxera, has made its appearance in Bas Languedoc, and is causing very great alarm amongst the cultivators and proprietors of vineyards. In one district, the Comtat, the vine has already almost disappeared.

— A CORRESPONDENT at Ismidt writes to the *Levant Times* as follows:—"Almost all our silk-worms have died, just when they were about to yield the cocoons. For thirteen years in succession this industry has proved a failure, and the inhabitants are now almost ruined." Several localities in Greece have been ravaged by locusts. A correspondent at Amphissa states that they have done great damage to the vines, and have even made a raid on the town. Letters from Samos report that the vines and fruit trees in that island have been considerably damaged by a tempestuous wind which lasted several days.

— THERE is one point, says the *Pall Mall Gazette*, in connection with the present appearance of Leicester Square which hardly receives the attention which it deserves. We speak of the beauty of the parks with their borders full of flowers arranged with mathematical precision, and we exclaim against the hideous disorder of Leicester Square, forgetting that there is beauty in its wildness. Were Leicester Square turned into a garden to-morrow, it would lose much of the charm which it now possesses in the eye of an artist. A few forest trees, rocks, and wild ferns, with a waterfall might improve it; but it would be a great mistake to destroy its character by turning it into what is now by courtesy called a garden. Never, perhaps, in its whole career, did the statue appear to such advantage as now in the hour of its ruin. We have succeeded in "banishing every appearance of art" from the square, we have only now to expunge all "traces of the footsteps of man," and we shall at last have one sight in London which, in the matter of true taste, leaves nothing to be desired.

— VICTORIA, says the *Argus*, has now growing 9,672,341 vines, and South Australia, 6,049,343. For New South Wales there are no returns. South Australia has 5,820 acres of vineyard; Victoria, 5,446, and New South Wales, only 3,906. Again, notwithstanding the falling off in the growth of the vine in South Australia, that colony makes \$95,795 gallons of wine in the year, while Victoria only makes 629,219 gallons, and New South Wales, 460,321 gallons. But Victoria sells a large quantity of her grapes for table use, instead of converting them into wine, and New South Wales does the same to some extent.

— THUNDERSTORMS, accompanied by deluges of rain, are reported to have occurred lately in all parts of the country, and in some instances great damage has been done. On the evening of the 25th instant, a large elm tree, growing at the back of the gardens at Bisbrook Hall, Rutlandshire, was struck by lightning, the electric fluid passing from one of the top branches down the trunk, to within a foot of the ground, tearing off a strip of bark three or four inches wide, some of the fragments being scattered twenty yards from the tree. At Birmingham, the Royal Horticultural Society's show ground has been a sheet of water, and hundreds of gardens in various places have been injured. What a hard time the tender bedding plants are enduring this year. The longest day past, and some only just planted out! The recent hail storms have been very severe on old-fashioned greenhouses glazed with thin glass. One that we have seen at Edgbaston had 300 panes broken by hail; and at Harworth, hailstones of a prodigious size fell, breaking down trees, smashing glass, and washing turnips and potatoes in many instances out of the ground.

— EFFECT OF GAS ON TREES.—A Frankfort journal records the result of some experiments that have been made at Berlin to ascertain the effect which gas has on trees the roots of which are exposed to its influence. Three trees were chosen for this purpose—two limes and a maple tree. The gas was conveyed in subterraneous tubes to within three or four feet of each tree, and was dispersed into the soil by holes furnished with brass gratings, in order to obviate the obstruction of the pipes. At the end of two months the roots were uncovered, when all the small fibres were found to be dead. The bark of the strongest roots was rotten, and even the body part changed. After two months and ten days, the gas was cut off, to see if the trees would recover. The maple showed no signs of life, but one of the limes again became covered with leaves, although bearing unmistakable appearances of ill-health. The poisoning manifested itself much more rapidly in that part of the earth which had remained compact, than in that which had been loosened. These experiments, followed up during a year, leave no doubt as to the danger to which trees are subjected when exposed to the infiltrations of gas a short distance from their roots.

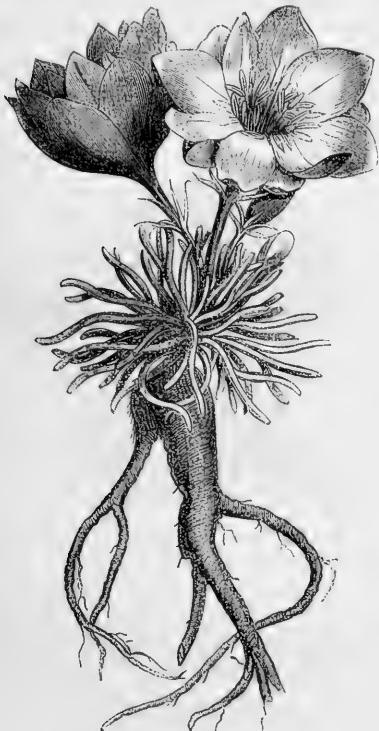

— HAMPSTEAD HEATH.—When this became public property, it was wisely resolved that, with the exception of putting down certain nuisances which had been permitted to flourish there when this spot was popularly regarded as No Man's Land, the heath should remain in that wild condition which in the eyes of sensible persons is its chief charm. It appears, however, that a much greater change than might be expected from this declaration of principles has come over the spirit of that beautiful suburban retreat. The old freedom is gone; the passion for rules and regulations has set in; and now the Cockney attracted thither in quest of the picturesque takes his pleasure under the stern eye of a beadle, ever ready to pounce upon him for some trifling breach of the new bye-laws of the local authorities. Thus it happened that a well known authoress was the other day seized and maltreated because she had gathered there a few ferns. The beadle in this case it is true has been fined by a magistrate, but this was clearly explained to be only because he had used a little excess of roughness in the execution of his duty. Such facts are enough to disturb the spirits of Leigh Hunt, John Keats, and all the other poets and essayists who have celebrated the old charms of the Vale of Health. No doubt the beadle is an inevitable result of the new condition of things at Hampstead; and rules and regulations cannot be avoided. It is to be hoped however, that the authorities will revise their laws on the principle of permitting the utmost amount of freedom which is compatible with decency and the comfort of the public. The heath is not exactly a pleasure garden; nor are its plants and wild flowers in the same category with the flower beds of Hyde Park and Kensington Gardens. Gathering ferns in a comparatively wild place is in itself a harmless, and may be an instructive, amusement; and it is hard to believe that any appreciable diminution of the beauty of the heath could result from it. The highly impudent functionary who illustrated the unfortunate authoress, should at least be directed to hold his hand until fern-gatherers have been proved to be a serious nuisance.—*Graphic*.

THE FLOWER GARDEN.

SPATLUM.

(*LEWISIA REDIVIVA*.)

This plant was discovered on Lewis and Clark's expedition, and was named by Pursh in honour of its discoverer. The specific name "rediviva" (lives again) was given on account of its remarkable vitality. The herbarium specimens brought home by Lewis were planted in a garden in Philadelphia, where they grew for a year, and some specimens collected by Douglas were planted in London, and grew, but for a short time only. Our engraving shows the plant of about the natural size, though the root grows much larger than we have represented it. The narrow, succulent leaves grow in clusters, from the centre of which the flower-stalks arise; these each bear a single

Spatium (*Lewisia rediviva*).

rose-coloured flower, which, like the Portulacas, to which it is closely related, remains open only during sunshine. The leaves die away soon after the flowers open, and the above-ground career of the plant occupies but a few weeks. The root, which is large for the size of the plant, is interesting as affording an important article of food to the Oregon Indians, who call it "Spatium," or "Spat'lum." It is also known to the French Canadians as "Racine amere," or bitter root. The root is covered with a dark-coloured bark, but the interior is white and consists largely of starch. The roots are boiled and used by the Indians as food, and though bitter, are very nutritious. It is said that three ounces of the dried roots will be sufficient provision for a man undergoing great fatigue. We do not know the exact range of the plant. Our specimen came from

Montana. It has been found in Colorado, and is abundant in Oregon.

[The preceding description, from our excellent American contemporary the *Agriculturist*, refers to one of the handsomest and most interesting rock-plants ever introduced. It is now in a few of our collections, and will, we hope, soon be easily obtained.]

THE BEST PÆONIES.

In examining a collection of Herbaceous and Tree Pæonies lately, we have decided that (although all are ornamental) there are in reality but a few worthy of cultivation. Of these the following is a list:

Tree Pæonies: Bijou de Chusan, Carolina, Colonel Malcolm, Comte de Flandres, Donckelarii, Elizabeth, fragrans, maxima plena, Lamberntiana, La Ville de Saint Denis, Louise Monchelet, Madame Stuart Lov, Osiris, Ranierii, Jules Pirlot, Rinzi, Rosa Mundii, Triomphe de Vandermalin, Vandermaeli, Van Houttei, and Zeobia. This list of twenty plants is chosen from one hundred and fifty varieties at least.

As for the Herbaceous Pæonies, the best are: *Anemoneflora*, *Aurea ligulata*, *Anemoneflora rosea*, *Etoile du Phétion*, *La Brillante*, *Nobile*, *pourpre*, and *striata elegans*, to which, without spoiling the others, may be added the common officinal Pæony, with reddish-purple flowers.

Among varieties of *Paeonia edulis* or *fragrans*, those which appeared to us the most beautiful are: *Abel Carrière*, *Alba sulphurea*, *Ambroise Verschaffelti*, *Boule de Neige*, *Buyckii candidissima*, *Doctor Caillot*, *Duc de Cazex*, *Duchesse de Nemours*, *Etendard du Grand Homme*, *festa maxima*, *Jupiter*, *grandiflora nivea plena*, *Madam Lemoinier*, *Madame Jules Caillot*, *Mathilde*, *Modeste Guérin*, *Papaveriflora*, *Prince Pierre Troubetzky*, *sulphurea*, *Triomphe de l'Exposition de Lille*, and *Washington*.

In this series, where all are beautiful, we have only mentioned "the flower of the basket," and such as all lovers of good plants ought to possess. As to those who are making a collection rather than a selection, they can increase them tenfold without falling into mediocrity.—*M. Carrière in "Revue Horticole."*

YELLOW WALLFLOWERS.

WE have, somehow or the other, come to regard the dark Wallflower as the one to be cultivated, to the almost entire exclusion of the yellow self-flowered varieties. Probably the dark varieties have come to be cultivated on account of there being a wealth of spring-flowering plants bearing yellow flowers, such as *Alyssum saxatile*, *Cheiranthus Marshallii*, *Doronicum caucasicum*, &c.; and also because many acres of dark Wallflowers are yearly grown round London for the supply of flowers to the London markets. I should think bunches of a good self-yellow would sell as well as the dark one. Efforts have been made from time to time to improve the yellow Wallflowers as cultivated. About ten years ago a very fine variety was raised by a Mr. Graham, at Cranford, near Hounslow, by means of careful seeding and persistent selection through many generations. The aim Mr. Graham set before himself was to produce a yellow Wallflower in which the colour should be pure, the flowers large, and the form good. This he did eventually attain; but I never heard of its being distributed. The best strain which I saw last spring was that known as the Tom Thumb, a kind which was considerable taller in growth than the strain known as the Belvoir Dwarf Yellow, but of a pure golden hue, and the flowers were of excellent form. Both this and the Belvoir strain can be used with excellent effect for the decoration of the flower garden in spring. One should see the dwarf yellow wallflowers as used at Belvoir Castle, in order to appreciate fully their useful floral service. I have always found a light, open, moderately rich soil to suit the wallflower best. In a stiff soil it often makes a strong tap root, but few side roots, and when excessive wet comes, the tap root will frequently rot. In a light free soil the roots branch in all directions, the plants thus get a good hold of the soil, and do much better in consequence. At Belvoir Castle so great a tendency is there on the part of the wallflowers to throw down this tap root, instead of making side roots, that Mr. Ingram finds it necessary to construct temporary brick pits in which to grow them during the summer. A line of bricks is placed at the bottom of a trench sideways and on their flat side, with lines along each side of them, so forming a kind of drain or trough; these are filled with soil, and the wallflowers transferred to them from the seed beds. The bricks at the bottom prevent them from throwing down a tap root; they therefore form branching rootlets, and stand much better when transferred to the flower beds in the autumn.

R. D.

THE SUNFLOWER.

BY T. S. JERROLD.

Of late years the cultivation of the Sunflower, together with a number of other old favourites, seems to have been much neglected; and yet it is a most valuable plant, and one that would well repay much more extensive cultivation. Of the Sunflower there are several kinds that are generally known—*Helianthus annus* (annual Sunflower), *H. multiflorus* (perennial Sunflower), *H. tuberosus* (tuberous-rooted Sunflower, or Jerusalem Artichoke). I have directed my attention more particularly to the first-named of these three, viz., *Helianthus annus*, which I have grown for the last four seasons with such success that I have brought my plants and flowers to a gigantic size. In Mexico the Sunflower attains a height of twenty feet, bearing flowers a foot or more in diameter. My plants have exceeded this in every particular, except in height, twelve feet being the maximum; the flowers I have grown are forty-eight inches in circumference, the leaves two feet long and almost as broad, the stems six thick and strong that they hold up without extraneous support the enormous heads of seed. It may not be generally known that in Germany, France, and Italy, Sunflower cultivation is believed to be effectual in removing the sources of fever. We have read of a landowner in Holland who planted, on the low banks of the Scheldt, three or four plots of Sunflowers, a few yards from his houses, with such effect that for ten years there has not been a case of miasmatic fever among the tenants of his property, although the disease continues to prevail in the neighbourhood. Two years ago the village near which I resided was visited with a severe epidemic of scarlet and typhus fever; I had at the time a large garden, and had had in it, the previous summer, a number of Sunflower plants distributed about; and the following season, when the fever had reached its height, I had a much greater number in cultivation all round my house. I did not think it at the time in connection with the cultivation of the Sunflower, but it is a singular fact, and almost confirmatory of the evidence of the cultivation of this plant being a preventive of fever, that my family enjoyed perfect immunity from disease, although in the houses and cottages around, whole families were stricken down, many cases proving fatal. It is a well known fact that the Sunflower feeds largely by its leaves, and absorbs a vast quantity of impure gases. The fibre of the stem can be employed in the manufacture of paper; from the seed a very fine oil, considered second only to olive oil, is extracted; and its use as a fattener of poultry is too widely known to need comment.

As an adjunct to the shrubbery, the Sunflower is most suitable, although it is now seldom seen. Cobbett says it is fit for nothing but to be seen from a great distance, "when the sight may endure it." We can not only endure the sight in an extensive shrubbery, but I think it appears very handsome in such a situation, its foliage when well grown being quite in keeping with its striking flower. The Sunflower is supposed to have derived its name from the idea that it always turned towards the sun, and Moore has no doubt tended to confirm this belief, when he says,—

"The heart that has truly loved, never forgets,
But as truly loves on to the close,
As the Sunflower turns to his god, when he sets,
The same look which he gave when he rose."

From continual observation of this plant, I cannot quite agree with those who deny that the Sunflower turns towards the sun, nor yet agree altogether with the poet in the constancy of the sun's attraction for the flower; for I have observed that when young the flowers have a tendency to follow the course of the sun, but as they grow larger and heavier this tendency ceases. For my own part I should rather believe the plant takes its name from the form and colour of the flower, more especially as it is also a native of Peru, in which country the sun was worshipped by the natives, and the representations of their deity bear a great resemblance to the flower in question.

Viola lutea.—Much has been said in praise of the improved varieties of this pretty little British flower, and no doubt they are most valuable as bedding plants, but I maintain that the true genuine article is quite able to hold its own against all its improved and hybridised offspring. A year or two ago I brought a wild plant home with me from the mountains of Derbyshire, and deposited it in a sunny corner of my rockwork. For the last six weeks it has been one golden mass, about the size of the top of a bandbox, the leaves being completely hidden by the flowers. It has been the admiration of all my visitors.—H. HARPER CREWE, *The Rectory, Drayton-Beauchamp, Tring.*

Matiolla incana.—If anyone wishes to have a most lovely purple bed towards the end of spring, I should recommend him to grow this plant, one of the gems of our British flora. I brought it from Ventnor, where it grows profusely on the cliffs, some twelve years ago, and generally have a bed of it in the garden. I sow it about the middle of July. It is advisable not to get the plants too forward, as both rain and frost in winter are apt to rot the crowns. It is very tidy in its growth, and most densely bright in its inflorescence. There is a fine white variety not infrequent at Ventnor, which I have lost and should be glad to recover.—H. HARPER CREWE, *The Rectory, Drayton-Beauchamp, Tring.*

THE BROAD-LEAVED SEA LAVENDER.

(STACIE LATIFOLIA.)

AN admirable representation of the above is given herewith. It belongs to a very distinct section of the Statices, to which, by some authors, the generic title of "Taxanthera" is given, presenting as it does, besides structural peculiarities of a well-defined character, a general appearance sufficiently distinctive—but possibly few will dispute the point with me when I say that we have such a number of names to store away in the recesses of the gardener's cranium, it will be quite needless to add to them where it can be avoided—so let it hold its old title of Statice.

A native of the wild salt steppes of Siberia, it was introduced into this country some eighty years or more ago, and is not infrequently met with in old-fashioned gardens. If I am not much mistaken, it will ere long take its true and valuable position in our modern gardens as well. Description is almost unnecessary, so perfectly has your artist given the effect of one of these tufts. Substitute for the stencilling of the mass of flowers as here presented, a soft lavender-mauve colour, and a lively green to the massive foliage below, and you have the plant before you. I ought to add, the height would be about two feet. So interlaced are the panicles of bloom one with another that, though individually weak, they mutually give

The Broad-leaved Sea Lavender (*Statice latifolia*).

strength and support one to the other. Blooming through the months of August and September, it should find a place in all gardens. But their estimate is not only to be reckoned by their appearance in the flower border, they are also most valuable additions to the bouquet or the epergne. So small are the individual flowers and delicate in their tint of colour, that, by a little careful manipulation and distribution amidst, and slightly above, the larger flowers that form the bouquet, they add a charm in either case that is all the more appreciated, in that the eye can scarcely detect the source whence it springs from. If plucked before being fully matured they will retain their colour for months, and have a pretty effect associated with Feather grass as a pendant round the sides, in a vase or other ornamental stand on the chimney-piece.

This section of the Statices rarely matures seeds in this country at least, and must therefore be increased by division of the root-stock in the spring-time, just after growth has commenced, and the operation must be performed with care and judgment, else there is a liability to lose the entire plant. There are many other species in cultivation varying slightly in habit, two of which are so distinct in the intense blue colour of their flowers, that I would just name them in passing as *Statice Tormentilla* and *S. Besseriana*; in each case the enhanced beauty of colour is more than counterbalanced by the straggling habit of the flower stems, owing to their length and weakness.

JAS. C. NIVEN, *Hull Botanical Gardens.*

Bocconia japonica.—Your recent reference to *Bocconia cordata* induces me to call attention to the superior claims of this species, which, though doubtless but a slight variety, botanically speaking, of the older plant, is for garden purposes distinct enough. And yet, when actual definition is attempted, it is difficult to point out any other distinctions than the greater robustness and far more rapid growth of the *B. japonica*. The foliage, besides its larger size, is I think more glaucous, or at least its glaucous tint is more uniform. With me this plant attains a height of upwards of seven feet, the stems at the base being as thick as the wrist. *B. cordata* in the same soil does not reach nearly the same size, and is far less effective, though of the same age. I believe the *B. japonica* has several aliases, two of which are *B. yedoensis* and *B. cordata* superba.—WM. THOMPSON, Ipswich.

Planting Aster.—The only way of planting these successfully for exhibition is that mentioned by "Amateur" (see p. 633). I saw some the other day planted in a similar way. Each of the beds contained four rows about eight or nine inches apart, and though only planted some ten or twelve days from this date, they were looking so exceedingly well that one looking at them from a distance might easily have mistaken them for rows of lettuces. The advantage which this mode of planting has over all others is, that after the holes have been filled with water it is allowed to settle down into a thick mud. The plants are then inserted in the holes and pressed firmly with the hand; no additional watering is then necessary, while if the plants are put in as the holes are made, after-watering is necessary; and if not carefully done the plants get dashed to the ground, often never to rise again so as to reach perfection. The plan described above is certainly an expensive operation; but what is worth doing at all, is worth doing well. Aster grown here in this way last year carried off several leading prizes at our horticulture exhibitions.—G. D., Cambridgeshire.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Echnothera bistorta Veitchii.—This is a capital plant for old walls or buildings, if sown in autumn in conjunction with the lovely bright and cheerful little pale plant *Eruca sativa*. On the north side of a stone wall in the kitchen gardens at Braham Hall, Camb., I have seen this latter growing and blooming profusely, split as it were all over the wall and border.—J. CHATRE, Cambridge.

Tulipa oculus-solis (*var. persica*).—In Mr. Green's garden at Ravensbourne Park, I lately saw a fine clump of this beautiful Tulip, which struck me as being much superior to many of the double varieties we now cultivate. Its habit is bold and striking; its flowers brilliant scarlet with a dark-blue eye. Planted in the margin of a shrubbery or amongst herbaceous plants, it has a fine effect. In my opinion it should occupy a conspicuous place in every garden.

The Many-stemmed Sandwort.—This resembles the pretty little *Arenaria laevigata*, but is likely to become as popular in consequence of its habit of creeping over and adorning moist rocks without soil. It has, however, larger flowers elevated above the foliage, and its leaves are more ovate and ciliate. It well deserves a place in collections of alpine flowers. It has been recently re-introduced by Mr. Maw, of Bentham Hall.—J. C. NIVEN, Botanic Gardens, Hull.

Annuals.—The following six annuals are most desirable in every garden:—*Eschscholtzia aurantiaca*, orange; *Silene viscaria*, crimson; *Leptosiphon roseus*, rose; *Viscaria vicia*, white with a darter; *Coldenia heterophylla*, purple; and *Viola cornuta*, blue. I have just sown these, which will give a succession of bloom from May to the end of October by sowing early in spring and early autumn; viz.—*Limnanthes grandiflora* rubrum, *Viscaria cardinalis*, *V. carulina*, *Leptosiphon androsaceus*, *Erysimum Perofskianum*, and *Eutoca viscidula*.—J. C. Cambridge.

Edgings of English Ivy.—A novel feature of the fine kitchen garden at Combe Abbey is very compact edgings of the common English Ivy. As is well known, the fine ivy edgings about Paris are all of the Irish Ivy, as are most of those in England. In another place, however, I have seen the Hibernian Ivy is also useful for this purpose, differing from the Irish in its smaller leaves, not displaying the deep green of the Hibernian variety. These edgings were very simply formed by gathering young plants of the common Ivy in the woods. These edgings are very suitable for flower-garden use also, and require little attention.—W. R.

Clivedon Purple Pansy.—What has become of these? There used to be hardy and well constituted too, and opening its bloom so softly through the late wintry weather as other plants only do in the cost of forcing houses. It is indeed a pity that the Clivedon Pansy, so common in southern England could scarcely open its fair blossoms, mutilated as it was, by frost and strong winds, and bitter breezes, this Pansy should seem utterly regardless of the weather. Its condition at the Lower Grounds, Aston, on the days when the oak leaves and spruce points hung dead, was surprisingly beautiful. It is by far the best of the Pansies that bear the name "Clivedon."

Hardy Double Primroses.—What has become of these? There used to be four or more colours pretty common—the white, the lilac, the yellow, and port wine red. The white and the yellow are often seen, but how rarely the latter and the yellow almanac! A bramble garden, yet these are not only lovely in borders, but in pots. In fact, no plants can hardly be more useful or more welcome for the spring beautification of the conservatory or sitting-room. The perfume is most agreeable. For bouquet-work, the white and the purple—approaching to crimson—are admirable. Both colours are so pure, and they contrast well with each other. The form and size fit in readily with other flowers, and altogether, either for outdoors or indoors, for the house or the garden border, few flowers are more beautiful or useful than double primroses.—D. T. FISH.

THE FRUIT GARDEN.

FRUIT PICKING IN MARKET GARDENS.

MR. R. VARDEN, the well-known fruit grower of Seaford Grange, has recently made some interesting remarks on fruit-growing to the Central Chamber of Agriculture. Profits, he says, in the ordinary branches of agriculture are, as you know well, very small; and farmers have been blamed by statesmen and political writers for not exerting themselves more to grow secondary crops, which, from their softness or perishable nature, will not bear long carriage, and are therefore less exposed to foreign competition. Fruit is one of the most important of these, and is the branch in which, some twenty years since, on the partial failure of my sight, and consequent relinquishment of my profession, I embarked my capital. Though a minor branch of agriculture it is a large industry, there being, I am told, 1,600 or 1,700 acres of fruit gardens round London; and in Worcester, where I reside, there are from 1,500 to 2,000 round Evesham, 400 or 500 round Pershore, and 100 or so each at Eckington, Upton-on-Severn, Worcester, Ombersley, &c. I am not authorised by the owners of these plantations to speak on their behalf, so will confine myself to my own case, but our interests are very similar. My fruit garden is 120 acres in extent, of which 100 acres are occupied by an undergrowth of gooseberry and currant bushes. The fruit of 20 or 30 acres of the former are picked green, leaving about 70 acres of bush fruit to be picked ripe in five weeks, beginning at the rate of 10 acres per week, and ending with 20 or 25 acres, that being the proportion in which the public require it, and as the week even in favourable weather consists of only four and a half days, the last market being on Saturday, to prepare for which we have to leave off picking at one or two on Friday, the quantity of work to be done in a short time is immense, and if wet weather, which bursts the fruit, or intense heat, which scalds it, come on, picking the whole quantity is impossible. The great demand for labour is in the last two weeks, and usually employs from 200 to 300 women and children; and though we make the work as regular as we can, it is far from continuous or certain. It only lasts a short time, and the pickers must be had quickly and in great numbers. The word "agriculture" in Mr. Read's Bill evidently comprises such industries as these, and though I do not myself employ the children, but pay the mothers by quantity for picking, there is no doubt the provisions will apply to the case; and as the women and children come in crowds—the six or seven surrounding villages being closed for the time—neither I nor my bailiff know the children, and only a few of the mothers, and therefore could not, as in the case of hop-picking, examine their certificates, nor would time permit. I may occasionally have as many as sixty children under twelve years of age at work; but it is difficult to know who works and who does not. The entire family (except men and lads) is there. The babies are placed under the hedges in charge of the younger children, and the rest pick together, each family or little group of neighbours having its row of bushes to itself, and when that is finished going to another row; and at dinner time the younger children, with the babies, join the other members of their party. The wages of fruit picking are looked upon as a kind of clothing fund, and the occupation is most popular as a relief to the women after nine or ten months' indoor work at glove-making; they say they go to it just as rich people go to the seaside, and but for the rest it gives their eyes they think they should go nearly blind. The women earn £s. 6d. a day, and though this is nearly double what they get at gloving, it would not, as a rule, induce them to come to their work if their children had to be left at home, but together they earn £s., and that is sufficient to draw them. My hope, therefore, of being able to continue currant growing rests upon the suspension clause (8); and I fear it is insufficient, firstly, because occupiers of not less than 500 acres must join in the application to have it put in force, an extent of land greater than will be usually employed as fruit garden in one locality; hence gardeners will frequently be dependent on others to help them in making the application, and fruit-growing is scarcely popular with the farmers, because it makes labour dear; and, secondly, because the whole period of suspension is not to exceed six weeks, and it may happen that other employers of the neighbourhood may, by their industries being more popular with the magistrates, or by their getting the order of suspension earlier, leave very little time for currant picking. Then pea picking, strawberry picking, and the like, might require the early season, and gleaning and hop-picking the later. Of course it will be no use for me to grow bush fruit if the picking is in this way to be made a matter of chance or favour, and it is very hurtful to the feelings of a person like myself to have to apply for those permissions much as a publican does for his licence. I should prefer the operation of the Bill being confined to nine months, leaving July, August, and September positively free

for the different kinds of harvest work. But if that cannot be, I hope something will be done to diminish these difficulties. The quantity of fruit to be picked varies greatly from year to year, sometimes being double what it is in others; and if I once or twice applied for more time than the small crop required I should have the chance of its being lessened when the crop was large, and the extent of the crop is not known till the time of gathering. A single frosty night, even at the end of May, will sweep off a thousand pounds' worth of fruit, and blight destroy it to the last.

DERIVATION OF THE WORD "APPLE."

BOTANISTS generally ignore the use of any other than scientific names for plants, because it leads to a great deal of confusion in their nomenclature, the same name being frequently applied to two or more plants of widely different species, and sometimes of widely different genera. Nevertheless the popular names of plants are not merely empirical, but are founded, as the scientific names are founded, upon some peculiar feature or use of the plant. Of late years these popular names have become the object of very interesting research, as throwing much light upon ethnological history, the antiquity of various nations, and the migrations of the larger tribes of men. We cannot go into a lengthy account of these matters, or give the derivation of all the popular names in use; but we will give a few examples of the researches made as to the names of some common trees and plants. With the exception of the hazel nut, and some other wild berries, the apple appears to be the only fruit known to our European ancestors, as it is the only name not derived from the Latin or French. In the Zend or old Persian language, and in the Sanskrit, the name for water is "ap," and for fruit "phela"; hence etymologists think that the name is compounded of these two words, "water fruit," or "juice fruit." This corresponds with the Latin name "pomum," derived from "po," to drink; which is a somewhat curious coincidence. In Welsh it was formerly called "apalis," now "apfel"; in high German, "aphol"; in German, "apfel"; in Anglo Saxon, "aoble"; in Swedish, "apple"; and in Lithuanian, "obolys," or "obelis." This close similarity in the name as used by these various nations renders it highly probable that they all come from the same root or stock, and that such root or stock originally inhabited the western spur of the Himalayan Mountains.—*Canadian Naturalist.*

"Alligator Pear."—I have a stone of this so-called pear, brought to me from Brazil. It is now growing in water, in a glass jar, and has a mass of roots, and a stem about eighteen inches long; but I am at a loss how to treat it, as, under the above conditions, it refuses to progress. Can you help me?—A SUBSCRIBER FROM THE FIRST.—[*Persea gratissima*, the Avocado or Alligator Pear, is a common tree in tropical America and in the West-India Islands, where it attains the height of twenty-five or thirty feet. It has elliptical leaves, about six inches long, and bears large pear-shaped fruit, covered with a smooth brownish-green, or deep purple skin. The "pears" contain a large quantity of firm pulp, possessing a buttery or marrow-like taste, not at first relished by strangers, but highly esteemed by people familiar with the fruit. There are several plants of it in the Palm House at Kew, where they are kept in pots, in strong yellow loam, and treated otherwise as ordinary stove plants.]

Pine-Apples in the Bahamas.—The Rev. H. Bleby, gives an interesting account in "*Missionary Notices*" of distant circuits made in his district. Of Eleuthera he thus writes with reference to the pine-apple, which is largely cultivated in the island, and forms an article of considerable export:—"The people were busy shipping pine-apples, to the culture of which a large portion of Eleuthera is devoted. Many ship on their own account, either to America or England; others sell their produce to shippers at a price ranging from 2s. to 2s. 6d. per dozen. Schooners to America will carry each from six to eight thousand dozen; but English vessels carry a much smaller number, as the fruit has to be cut with the slips upon it, and in this way requires twice as much room as the other. They are cut green, to ripen on the voyage; and consequently the exported fruit never has the fully-developed flavour that it acquires when it ripens in the field. The shippers receive no pine-apples that do not measure in circumference 12½ or 13 inches; but it is not uncommon to find them 18 or 20 inches. A shipper told me that not less than a hundred cargoes have been sent from the colony this year. Sometimes a shipment realises a large profit; at others it is a total loss. Between Spanish Wells and Harbour Island, on the Eleuthera coast, two schooners lay at anchor. Scores of people were bringing the fruit from the interior to the shore in large baskets, each carrying, according to their strength, six, eight, twelve, or fourteen dozen. On the

sandy beach lay immense heaps of pine-apples, and the smooth sea all about was covered with boats employed in carrying off the cargo to the schooners. The vessels are frequently loaded in a single day, that no time may be lost in getting the perishable luxury to the market. As we passed along the shore we found no difficulty in getting a supply of yellow pines that had become too ripe for shipping, to refresh us on our way."

Crippled Peach Trees.—In reply to your Sevenoaks correspondent (p. 683), let me say that there ought not now to be, after our many years of experience in peach culture, any doubt at all that the peach is sometimes fearfully and even fatally injured by severe frosts when its young leaves are unfolding in early spring. The trees will never be safe so long as we persevere in allowing the cold rains to fall directly on them, thus preparing them for the frosts that follow. Scrim or canvas is of little use so long as we have not a deep temporary coping (eighteen inches to twenty-four inches wide), which will ward off both cold rains and frost to a far greater extent than any contrivance placed like canvas, &c., merely before the wall.—F.

Relative Success of Fruit Trees on High and Low Land.—This we have had a good chance to test. Our old orchard is on elevated ground, inclining to the south; and another orchard (both of apple trees) is below the hill on the level. The soils are somewhat similar, that on the hill a little darker; both a deep soil, good for trees, though there is more clay in that of the lower orchard than on the hill. The trees grew well in both; there seemed little or no difference, and both bore well. The orchard on the hillside is still in good bearing, though it has been much neglected. That below has nearly died out. Some of the trees are entirely missing; others have a little life left, and a few show some success. With care the hill orchard might be made good for many years to come. The difference is decided in its favour, and this is our observation of other orchards (apple) as well. We prefer an elevated site, exposed to the winds. The fruit is sounder, and we find also it keeps much better. The trees also are smaller, and therefore the fruit is more easily picked. There is too less disease than in low-lying orchards.—Cultivator.

The American Strawberry Trade.—The strawberry trade, says the *New York Times* of May 24th, has now become one of the great features of the produce market, and during the season gives employment to a large portion of the community, if we include the growers and carriers as well as the wholesale and retail sellers of this one commodity. But a few years ago strawberries were among the rarities on the tables of the "upper ten," but now they are produced in such quantities as to be within the reach of even the most humble labourer. The States supplying the New York market with strawberries are North Carolina, Virginia, Maryland, Delaware, Pennsylvania, New Jersey, and New York, the names being given in the order in which the crops reach this city in any quantities. Up to within a few days ago but few berries came from any other State than North Carolina, and then in only such small quantities as to make them almost a rarity; but during the present week the Virginian crop has been added to that of North Carolina, and prices have come down in consequence. On Monday last the steamer from the James River brought into the market over 1,200 crates of strawberries, each crate containing from 24 to 60 quarts. On Wednesday 2,500 crates, or 100,000 quarts, were brought to the market. A steamer is expected on Friday next with over 5,000 crates of strawberries on board, making a supply of nearly 250,000 quarts. The majority of these berries will come from Virginia, and a few from North Carolina.

The Mistletoe on Fruit Trees.—Is the mistletoe injurious to fruit trees? It is appearing in various parts of my orchard.—KING PREP.—There has ever been a difference of opinion respecting the effects of this parasite upon fruit trees. Some growers tell us mistletoe does no harm, as they frequently find that trees on which it is found uniformly produce something like a crop, and that the apple wine—cider—made from it is of the best. In such cases, then, we may probably conclude that the parasite has acted much in the same way as the pruning-knife; but there can be no doubt that it weakens and injures the tree.

Science and Practice.—I quite agree with you (see p. 570), that it is high time to drop such distinctions as have been set up between science and practice. They have no existence in reality. That man has the most science who puts the most and the best thought into his work, and who brings most good out of it to his fellows. Judged by this standard, practical gardeners rank high as scientific men. Doubtless, the use of foreign tongues for classification and description has done much to originate division between so-called scientific and practical men. But you have at least hit one blot that ought to be instantly removed: Neither the Horticultural Society nor any other body concerned in the advancement of horticulture ought to perpetuate distinctions in name which cannot be sustained in reality. Within the wide range of horticulture there are many differing degrees of knowledge—great discrepancies of power and capacity; but our rough-and-ready division into two ranks only—the practical and scientific—is as misleading as it is humiliating, and I trust that we have nearly heard and seen the last of it.—D. T. F.

THE GARDENS OF ENGLAND.

WARWICK CASTLE.

THE FLOWER GARDEN.

WARWICK CASTLE is one of the grandest of the few castellated residences of mediæval times which are still perfect, and still inhabited by collateral descendants of an ancient family. It is, in short, one of the most interesting and remarkable of those fortress-homes, which illustrate so strikingly the form and spirit of English civilisation under our Plantagenet princes. Even since the ever-to-be-regretted devastations of the late fire, enough of the ancient pile remains, in all its original grandeur, to command the strongest interest of the historian and archaeologist; and the restorations now in progress are so judiciously devised that little of the venerable associations will be missed. The parts of the interior destroyed by the fire were, in fact, of comparatively modern date, and in their restored form will be more in accordance with the ancient parts of the building than they were before. The place, which was once the home of the last of the great barons—of Warwick, the King-maker—will continue to be visited by tourists from all parts of the world, as a rare historical shrine; and such writers as Emerson and Hawthorne, from the great land of our cousins across the Atlantic, will come to it, and record the thoughts that moved them while visiting the grand old monument that still remains standing in the land of their fathers. They will sit beneath the great shade-casting cedars, or on the green knolls among the noble oaks of the park, and gaze upon the hoar antiquity of the great grey towers, and upon the glistening Avon, that winds its way through the sylvan scene, on its way from Stratford to the ocean. And they will be filled with more poetic and heart-stirring thoughts than any that could be roused within them even by the glorious scenery of their own wondrous Hudson; for at Warwick they will feel themselves in the midst of the scenes trod by Shakespeare, and among which that matchless poetry was dreamed out, which is their inheritance in common with us, and with all English-speaking nations.

It is a somewhat curious fact that in the whole range of Shakespeare's works, little or no allusion is made to the noble pile of Warwick Castle or its twin brother Kenilworth, though he was living at the time of the costly entertainment given to the great queen; and as Kenilworth is but a walk from Stratford, he may actually have been, as a youth, among the mummers of the festival, and have pointed some of the merry jests that doubtless enlivened the revellers with good, rough, laughter-stirring Warwickshire wit. Yet, although scenes in his "Henry VI." are laid at Warwick and its immediate neighbourhood, no word is said about the castle or that of Kenilworth. The explanation may be, that anything bearing upon the doings of the all-powerful Robert Dudley, or the doings at his great castles in Warwickshire, especially the story of Amy Robsart, was dangerous ground for a poor playwright to tread.

The first aspect of the castle, as seen from the bridge over

the Avon, or at points where its grey towers rise picturesquely above the ramparts and over the noble trees by which they are partially concealed, is very impressive, and on passing the entrance gates and advancing up the hollow way cut in the red sandstone rock, which rises on either side to the height of twenty or thirty feet, this effect goes on increasing. The rocky sides of the approach are clothed with ferns and tangled festoonery of brambles and other trailing kinds of brushwood, with here and there a seedling ash or sycamore rooted half way up in the rock, and shooting its main stem upwards towards the light, while straggling branches droop heavily downward. In some, these branches meet from either side, and form a bower of greenery overhead; while through the open spaces the tops of the great trees near the castle are seen —venerable cedars, and oaks, and elms.

The green lawn within the ramparts, once the spacious castle-yard, where the men-at-arms were mustered, is studded with fine trees, and a noble walk leads from thence to a passage through a part of the ancient rampart, by which the conservatories and the flower garden are approached. This walk is well contrived for effect. Looking back upon the dense masses of shrubbery that partially conceal the rampart and its turrets,

and above which rise the ancient towers of the main structure, nothing can be finer than the general effect of the fine natural picture thus presented. Pursuing the course of this walk, the aspect of the park and its grand oaks, with the more distant view of the Avon, disclose themselves by degrees; and at length, when the noble conservatory (called the winter garden) is reached, which contains that fine monument of antique art so well known as "The Warwick Vase," the view becomes grand and fascinating in a very high degree. Immediately in front of the conservatories, the

Warwick Castle.

extensive geometrical flower garden has been laid out; it is in very good taste, and with its architectural dressings, which are bold and appropriate, it forms an excellent foreground to the sylvan prospect beyond. The view is one of the finest specimens of park scenery that can be conceived. The Avon winds its silvery way through wide glades and meadowy slopes of deep rich green, which are bounded on either side by massive woods of ancient trees; the tufted summits of which, when their varying tones of vivid green are seen in bright sunlight from the conservatory terrace, produce, in combination with the gleaming course of the Avon, an effect of rich sylvan luxuriance which can scarcely be surpassed even by the celebrated view from Richmond Hill.

Our engraving of the castle has not (which is much to be regretted) been taken from the best point of view. Instead of selecting that from the bridge, which commands the broadest part of the Avon, with the cascade, and shows the terrace of the castle which overhangs the river, the artist has taken his standpoint on a spot some distance above the bridge; in consequence of which those interesting features are entirely concealed. But neither this bad selection of the point of view, nor even a worse, could prevent the grand old towers and the great flank of the castle, as seen in the present

instance above an ivy-covered arch of the bridge, from forming a most picturesque group of objects.

The park at Warwick Castle is small, but some of the trees are very grand specimens of their respective kinds; especially the oaks, one of which presents a curious Banyan-like aspect, from some of its vast and far-spreading arms, where they rest upon the ground, having struck root and sent up stalwart young stems, such as are seen surrounding the great sacred tree of India, and forming columns to support its far-extending shades.

NOEL HUMPHREYS.

THE LIBRARY.

HOW PLANTS BEHAVE.*

ONE of the best botanists alive, and, as we think, the happiest of all teachers of botany, has added another pleasant little book to those he has already written for young people. Those who have read that most charming botanical work for young people, "How Plants Grow," will be prepared to welcome the same author's account of "How Plants Behave," in which the latest scientific investigations as to the movement of plants, and other interesting matters are presented in a style that is sure to fascinate young people, and at the same time be welcome to older readers.

That plants "behave" at all will be new to many, for most persons are accustomed to regard plants as inanimate objects, with a few exceptional individuals, like the Sensitive Plant, that manifest visible motion.

A large portion of the little book is devoted to explaining the, to us, wonderful relations between insects and plants, to the various distinct ways in which plants climb, and to the various other phenomena which we call curious. Although written for young people it is likely to be equally interesting and instructive to all readers. We trust it may find many readers on this side of the Atlantic.

DOMESTIC BOTANY.+

MR. JOHN SMITH has long been well known to the botanical and horticultural public, not only from his many botanical works, but also from his official connection with the Royal Gardens at Kew. His exertions in promoting the growth and study of Ferns are well known. On the present occasion we find him coming before us as a writer upon another branch of botanical science; and if "Domestic Botany" is, as a whole, less satisfactory than some of his other works, much will be found in it to interest and instruct the reader. It differs somewhat both in scope and purpose from any of Mr. Smith's previous works. We cannot help expressing an opinion that the introductory portion on the "parts, structure, life, organism, and classification of plants" would have been better omitted. It adds nothing to our knowledge, introduces several new and unnecessary terms, and occupies space which might well have been devoted to an extension of the latter part of the work. In this latter portion we find many notes connected with matters of especial interest to our readers, such as the introduction and first cultivation of garden trees and shrubs, notes on certain individual examples, &c. Among the latter we may cite the reference to "Napoleon's Willow." A twig from the willow growing over Napoleon's grave at St. Helena was received at Kew in 1825. Crowds of people came to see it, and it was an object of reverence to French visitors. We believe that many years since, before Kew Gardens became national property, a great many people came down from town to visit this interesting relic, and, on being refused admission, broke open the gate. In 1867 this tree was cut down—why, Mr. Smith does not inform us; it had then attained the height of forty feet.

The age of some of the plants now at Kew is in some cases very great. Thus, three specimens of the Purslane tree (*Portulacaria afra*), are nearly one hundred years old; and a tree of the American Sassafras (*Laurus Sassafras*), forty feet high, is of the same age. Again, a plant of the Canary Isles Campanula (*Canarina Campanula*), has withstood all changes for more than fifty years, producing annually succulent stems about three feet high, bearing pretty bell-shaped flowers of a rusty colour. In old specimens of Magnolias, Kew is

very rich; two Tulip trees, seventy feet high, are more than a hundred years old; a *Magnolia grandiflora*, "for many years growing against a wall, but now for more than twenty years standing fully exposed," with a height of twenty-three feet and a girth of three feet, is of the same age; and of *M. conspicua*, which was introduced in 1789, "one of the original plants is still growing at Kew."

We might cite much more that would interest our readers, did space permit, but the above extracts will show that, even from a gardening point of view, much worthy of note may be found in "Domestic Botany." The work is by no means perfect; indeed, a good handbook of economic botany has yet to be written—but it is likely to be useful to many who like to know something about the plants and plant-products which they are constantly coming across. We regret that Mr. Smith, after demurring to the number of botanical terms in use, should have found it necessary to invent others, which have the disadvantage of being new, with no commensurate advantages; and we should have liked a more comprehensive index, and a less conspicuous sprinkling of typographical errors. But "half a loaf is better than no bread," so we would rather record our obligations to Mr. Smith for what he has done, than find fault with him for what he has omitted to do.

GARDENING ROUND LONDON.

(DURING THE PRESENT WEEK.)

BY OUR SPECIAL REPORTER.

PRIVATE GARDENS.

Indoor Plant Department.—Begonias will soon be available for conservatory work; the most forward of them are being shifted for the last time into strong soil, consisting of yellow loam mixed with rotten manure. Show Pinks, Carnations, and Picotees, if required for exhibition purposes have their stems and flowers considerably reduced in number; the flowers that are left have a piece of matting or worsted tied round their middle, to prevent them from bursting. Chorozemas are being shifted into a compost of rich turfy peat, fibrous loam, a little leaf-mould, and sand; they are afterwards kept in the warmest part of the greenhouse for a time. To such as have not been repotted this season, a little clear manure water is given. Kalosanthus are neatly trimmed and occasionally supplied with manure water. Fuchsias are shifted into their flowering pots, and syringed twice a day; they are fastened to one central support, and any shoots having a tendency to get too long or weak are either pinched in or altogether removed. Such Camellias and Azaleas as have flowered early, and have nearly completed their growths, are gradually inured to an extra share of sunlight, preparatory to their being set outside; the later ones are still kept rather close, well shaded and syringed. Gardenias are kept in a warm moist temperature, and on the first appearance of insects they are immersed in tobacco water. Monstera deliciosa when grown against a wall in a warm moist shady house is frequently syringed and plentifully supplied with water. Their fruits, if likely to become too heavy, receive some kind of support. Vanilla is trained on walls and on boards, over which a layer of sphagnum is placed for the retention of moisture. Rivinas, if not required for present use, are cut back, so as to induce fresh growth and the production of berries.

Orchids.—Such as are in flower are moved to the warmer parts of the conservatory; those advancing are encouraged, whilst some are being retarded, in order to prolong the flowering season. Wood-lice are trapped by means of potatoes being placed here and there; examining them daily, and destroying such as are found on them; a little cotton wool around the stems or flower stalks also prevents them from ascending. Top-dressing and renewing of blocks are operations now receiving attention. Abundance of moisture is given to the roots, and the atmosphere is also kept moist throughout, bright sunshine being excluded by means of shading. As regards heat, that is economised by closing early. Ferns are still being placed out of doors, any damaged or weak fronds amongst them being removed. Greenhouse Ferns are shifted as they may require that attention; others are merely top-dressed. They are closely shaded, but are allowed plenty of air. Baskets are now being filled with Ferns, placing an upright-growing kind in the centre, and a few pendulous ones round the sides, together with mosses, variegated grasses, Strobilanthus, &c. Some Filmy Ferns are being potted, using a spongy material and pieces of open sandstone for that purpose.

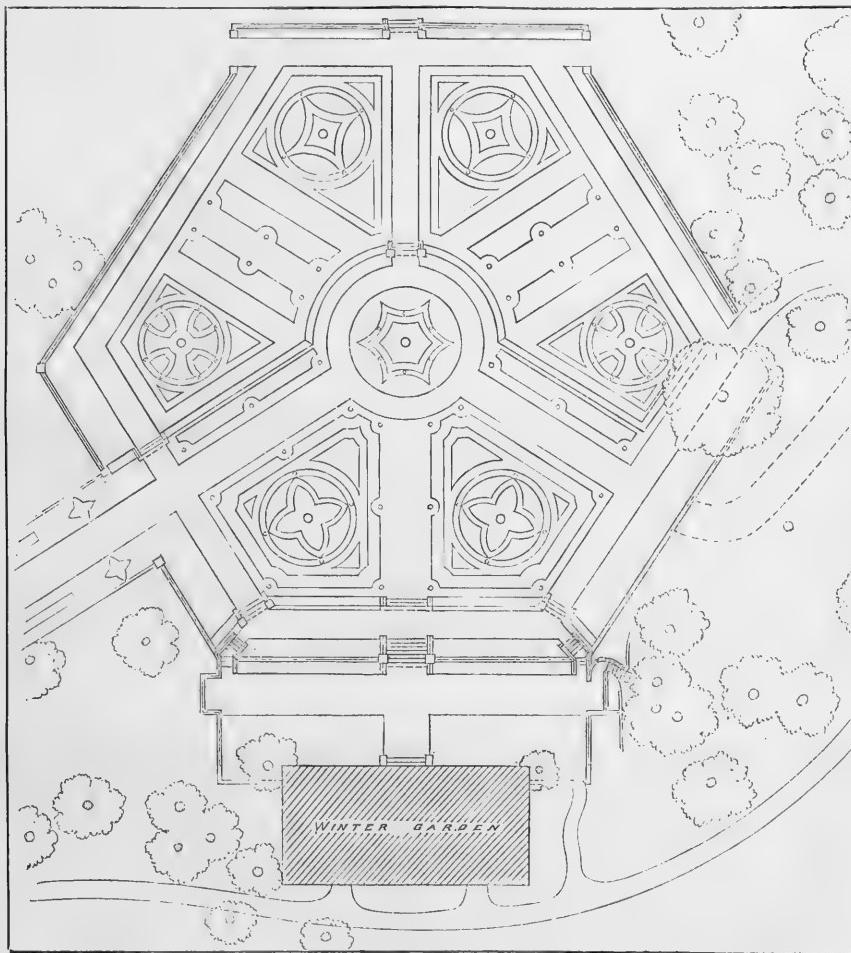

Pits and Frames.—Hardwooded plants are being potted as required, and are placed in frames kept rather close for a time. Soft-wooded plants for late conservatory decoration are being shifted

* "How Plants Behave." By Asa Gray. New York and Chicago: Ivison, Blakeman, Taylor & Co.; London: Trübner.

+ "Domestic Botany: an Exposition of the Structures and Classification of Plants, and of their Uses for Food, Clothing, Medicine, and Manufacturing Purposes." By John Smith, A.L.S. London: Robert Hardwicke.

into their flowering pots, kept rather close for a few days, but afterwards freely exposed, and stopped. Shoots are taken off Cinerarias planted out, potted singly, and placed in cool frames. The ripe seeds of Auriculas are gathered, and seedlings potted as is necessary. Fine foliaged Amaranthus are potted as they require it, using a rich, open compost for the purpose; the pots are then plunged in a spent hotbed and kept near the glass, the sashes being

given. Anything subject to wind-waving is firmly staked, pieces of cloth or other soft material being applied so as to prevent the ligature from damaging the bark or wood. Canterbury Bells and other tall-growing Campanulas are staked, or if grown in lines they are supported by being attached to a cord running from end to end, and fastened at intervals to small stakes. As the earliest flowers of Antirrhinums, Delphiniums, &c., get past their best, the flower spikes

The Flower Garden at Warwick Castle.

tilted up a little at back and front, to induce stocky growth. Hardy Orchids are kept in cold frames, protected from heavy rains and bright sunshine, but abundantly supplied with air.

Flower Garden and Shrubbery.—Now that the flower garden has been planted, operations for some time to come will consist in loosening the surface, and in supplying the weaker-growing plants with water. For this purpose, little basins of earth are formed around the base of each plant in order to prevent the water from escaping. To the stronger deeply-rooting plants no water is yet

removed in order to encourage the laterals. Cerastium, when used as an edging to shrubberies, is sometimes at this season permitted to flower quite freely, and after a time, when whatever may have been planted behind it begins to cover the ground, the Cerastium is cut over, but not quite close, and encouraged to push again. When used as an edging to flower beds, we need scarcely say, it is never allowed to flower. Roses are frequently syringed in order to keep down insects; tobacco water being used if the flowers have not expanded. Standards having heavy tops are securely

staked. Imperfections in shrubberies and hedges are being rectified by means of the pruning-knife.

Indoor Fruit Department.—Figs should never be allowed to make shoots beyond the fourth or fifth joint; sometimes there is a tendency to over-luxuriant growth, but this is kept down by using poorer soil, and watering with only pure water; frequent syrings are given and a moist atmosphere maintained. The earliest crops of Peaches and Nectarines have some sort of protection provided for the falling fruit, such as a sheet of canvas in front, placed so as to receive the fruit as they drop off; or, instead, a doubled herring net, in the bottom of which is placed some soft hay or dried lawn grass. The borders are also covered over with hay or grass, so that should the fruit fall, the injury received would be immaterial. Pot plants are also surrounded with soft hay. Strawberries ripening fruit are kept a little dry, but this bright weather is apt to dry them too fast, consequently they require great attention; the next to the last lot for forcing is being introduced; their fruit is already formed. French Beans are kept well syringed, and the last ones in pots are being top-dressed; these will follow those at present beginning to bear, and will be succeeded by those sown in frames, which will be in their turn succeeded by those from the open air that were partly protected. Melons and Cucumbers have their beds top-dressed, and liberally watered; and thinning foliage, shoots, and fruit is attended to. This fine weather will cause Melons to set freely of themselves. Abundance of air is given, and but little fire heat is now required if the houses are shut up early.

MARKET GARDENS.

The rapidity with which vegetable crops have advanced during the last week or so is truly wonderful. Vegetable Marrows from the earliest planting now cover the whole space allotted to them, and are producing fruit abundantly. The earlier plantings in the open ground without any encouragement from artificial heat, are also in flower and otherwise advancing rapidly. Those planted out in the open fields, fifteen by six feet apart, without protection of any kind, have fairly started and so far are very promising. Where Cucumbers are grown extensively one or two men are kept purposely to attend to them. The plants are gone over every three days, thinned, and such fruits as are inclined to grow crooked are placed in glasses. During the hottest part of the day a little litter is scattered over the surface of the sashes, which are tilted up about three or four inches. Liberal waterings are also frequently given. Such as have been in fruit from the first of the season are being replaced by others from the reserve stock. Gherkins are being sown in lines, about three or four feet apart, and the seeds about four inches asunder in the rows, the ground used for them, if loosened for the previous crop is only cleaned, and worked up with a fork or hake, the lines drawn, and the seeds sown. French Beans are sown for succession in lines three feet apart. Sweet Peas are now producing a good supply of flowers for market. Wallflowers from this spring's sowings are transplanted into lines, twelve to fifteen inches apart, between fruit bushes, for blooms in the spring, and Stocks planted between lines of Roses, are now abundantly producing flowers fit for market. Where tall fruit trees are close together, and the produce likely to be plentiful, the under-cropping is removed, and a layer of loose litter is scattered over the surface, thus not only protecting the roots, but at the same time supplying nourishment to them; a mulching of this kind also preserves the falling fruit from being bruised.

Tomatoes have lately grown rapidly; those planted alongside old Mushroom beds are pegged down on the ridges as they advance. Stakes are applied to those planted in open spaces. A little soil is drawn to their base, so as to form a furrow or basin for the retention of water. The earlier crops are in bloom. Owing to the strike among the labourers, operations that ought have attention now are deferred or wholly neglected.

NURSERIES.

Indoor Plant Department.—Plants of the Sugar cane are being cut down and the joints inserted in pots in the propagating house; some of these produce two or three shoots, which will eventually be separated, preserving the roots, and potted singly. Pandanus are also propagated from the roots and side-shoots, also from seeds, which are inserted in pans of light peaty soil; after germination, the plants are separated, and treated as cuttings. Ardisias are now in flower, kept in a rather dry atmosphere, in order to set their fruit. Gardenias, which are found rather stiff subjects to grow, are liberally encouraged. Epiphyllums are tied, staked, and induced to grow freely. Bertalarias are kept in a steady temperature under hand-glasses in stoves. Vincas, Passifloras, Bougainvillesas, Dipladenias, and any other plants of which there is a scarcity, are being increased from cuttings in pots plunged in bottom

heat, under lights well shaded. Inarched Camellias are laid on their sides under hand-lights, i.e., if there is no room enough for them to stand upright. Primulas done flowering are kept fully exposed in cold frames. Calceolarias for seed are placed in cold frames. Newly imported Orchids are laid out on shelves until they start, or they are suspended from wires until they exhibit signs of vitality; any Fern roots found amongst them are potted and kept well shaded. Orchids of all sorts that have not been previously shifted or top-dressed this season are receiving that attention, as time permits; those in flower are moved under greater shade and kept drier than those in the ordinary house. Little or no fire heat is used, but the houses are shut up pretty early in the afternoons, so as to economise heat. Ferns are being raised from spores sown in pots, over which a piece of glass is placed, and moisture is supplied from saucers of water placed under them. These pots are kept well shaded, and as the plants come up, they are pricked off into pans and afterwards potted singly in thumb pots. They are generally kept inside frames within the propagating house.

Outdoor Department.—Beds of seedling conifers are frequently gone over and cleaned. Those sown in frames have the sashes removed throughout the day, but replaced at night. The sashes being covered with mats or other material. Two-year-old plants of Deodar are being turned out of their seedling pits and potted singly, and variegated Ivies are kept in cold frames well aired and watered. Tree Carnations in pots are plunged in coco-nut fibre in beds in the open air. Hardy Ferns are also plunged in the same material at the foot of shady walls; some of the finer kinds are kept in frames, and shaded from bright sun. Pyrethrums are turned out of pots and planted in beds, single stakes being attached to each. In order to preserve the blooms of Pansies for exhibition, they are shaded from strong sunshine. Herbaceous plants are staked, shaded, and well-watered. Hardy climbers are trained as they advance in growth, confining them to single stakes. Nurseries are now busy plaiting out their remaining bedding plants. Beds hitherto occupied by spring bulbs, are being forked up, and planted with sub-tropical and other summer flowering plants.

SMOKE IN OUR GREAT TOWNS.

The great smoke nuisance flourishes, apparently unheeded, and the sky, already filled with vapour drawn from the sea, is darkened and made foul with the black vapour rising from a thousand factory chimneys. Many a day that seems dark, dull, and unwholesome in our great towns, is bright and cheerful enough at five or six miles distance from them. The fact is, citizens have their being in soot, and everything that is about them is darkened and discoloured by its presence. It changes the blue of the heavens into a dingy grey, or obliterates it altogether. It covers every leaf in our gardens, hinders the growth of the plants, spoils the colour of the blossoms, and kills the trees.

Of course, we are thoroughly well aware that the commercial prosperity of towns depends upon the activity of their manufacturers. These must not be discouraged. Blight not the soul of your manufacturer, or you shall rue the day. All this we know—and believe. But then lately we have seen a sight, and it was this:—We saw an old town, a manufacturing town, possessing great prosperity, lying in a valley between two ranges of hills. Standing on one of these hills, we could look right across to the other range, distant some ten miles. Every part of them was visible. The woods growing at their feet, the bare hillsides, and the outline of the hill-tops against the sky, were all plainly to be seen. And yet at our feet was the town, and above the houses of the town there rose a very forest of factory chimneys. It was the busiest time of the day, and yet out of all these hundred mouths a puff or two of smoke only came now and then from three amongst the whole number. There were the chimneys, but they were smokeless. Their tops were mostly well blackened with the sins of old times, but the day of evil-doing had passed—let us hope for ever. The secret of this phenomenon is easily told: in that town the law is too strong for the manufacturers. He has his difficulties to contend with. He also burns coal, and has to employ stokers. But he has been taught to educate his stoker to ply his calling properly, and the result is that the factory chimneys do send out no smoke except for about five or ten minutes, once or twice a day. The town in question is clean, its streets are bright, and the foliage surrounding it is unspoiled with soot. Surely, that which is done elsewhere so successfully might be put in practice here. We have the law, but its arm is not strong; we want the force of public opinion to compel our magistrates to seek out the offenders, and to punish them as they deserve.—*Birmingham Morning News.*

THE GARDEN IN THE HOUSE.

MARANTAS.

AMONGST the foliage plants that decorate our stoves, few are more deserving of admiration than Marantas; coming, as most of them do, from wet parts of tropical America, they require to be grown in a moist warm atmosphere, and consequently do not well bear removal to rooms or conservatories, except for a limited time. This is much to be regretted. The well known *Maranta zebrina* was for many years almost the only one amongst the ornamental-leaved section of the genus that was commonly found in stoves; but of late years many very beautiful species have been introduced. Amongst them, *M. Veitchii* is probably the most striking, the leaves being

The Maranta as a Vase Plant.

purple underneath, and deep green above, with yellow markings near the midrib. An engraving of an interesting variety accompanies these remarks, and we shall shortly figure some of the broader-leaved species of this fine genus. W. T.

CULTURE OF PLANTS IN ROOMS.

(Continued from p. 680.)

SOLIUS.

THE humus, which has been spoken of, consists exclusively of decayed vegetable matter, and for many plants is used either pure or mixed with sand, or is employed to improve a poor loam. For plants in pots all kinds of humus are most suitable when they are composed of vegetable matter not wholly decayed. Humus of this description feels soft and elastic to the touch, but that which consists only of wholly decayed matter, forms a fine, powdery mass, hard to the touch, and which by itself is not adapted for plants, and even when mixed with other soil is far less suitable than humus composed of partially undecayed matter. We shall here add a few observations on the various kinds of natural soils which consist chiefly of humus, such as forest soil, heath soil, and moor or peat soil.

The first two kinds are found in dry localities, and are, according to the sub-soil on which they are found, and the vegetable matter of which they are formed, of very different values for plant culture. With regard to the sub-soil the following remarks may be made:—

Stony or sandy soil, as a sub-soil, is that on which forest soil and heath soil are not only most readily formed, but where they receive those elements which are most advantageous for plant culture, inasmuch as none of those matters which are injurious to many plants (as for example lime) can enter into their composition.

Besides, sand is a necessary ingredient in humus soil, and where it does not exist naturally, it must be supplied artificially. Much, or too much, sand will of course be found

where the soil lies very thinly on a sub-soil of pure sand, and the result will be that such soil will be poor and unfit for plant culture.

The deeper the soil lies on the sandy sub-soil, the less sand will it usually contain, and the more suitable will it be (at least the upper layers of it) for plants. This depth is due to local peculiarities, which favour the accumulation of vegetable matter and promote the speedy formation of a soil rich in undecayed and nutritious ingredients.

On stony or rocky ground exposed to the weather, and which contains a large proportion of alkalies, humus soil is very seldom found, as any that is formed here is speedily decomposed by the sub-soil, and is then washed away by the rains.

The names of forest and heath soil will almost explain their constituents. Forest soil consists of humus formed from the leaves of the trees, their wood, and lastly, under certain circumstances, from the plants which grow in the said humus. It is found in the deepest layers where these matters are carried away and deposited by the water of heavy rains. Heath soil, on the other hand, consists of humus which has been formed on open plains, where heath plants cover a wide area.

Forest soils will, according to the nature of the trees from the leaves of which they are formed, show very considerable differences in quality, in proportion to the quantity of alkalies and nitrogen which the leaves contain. Accordingly it is a matter of experience that oak woods supply one of the best and strongest forest soil, that beech woods afford one something inferior, woods of mixed trees a still inferior kind, and finally, that the soil in pine woods is only good when found in deep layers and mixed with the decayed roots and leaves of Vacciniums and other plants.

Heath soil consists either only of the remains of heath plants lying in thin layers, and is poor and uninteresting, or of dry moor and peat soil which has become covered with heath plants, such as *Vacciniums*, *Andromedas*, &c, and then approaches very nearly to peat soil in its character,

Moor and peat soil are very often confounded with heath soil. They are formed by the deposition of decayed vegetable remains on a wet sub-soil or in water itself.

During their decomposition they give out a great part of the salts which they contain into the water, and where they are cut off by water from the access of the air, they acquire an injurious sourness, and are consequently unsuited for plant culture.

But where, on peaty moors, the surface is continually raised by the deposition of vegetable matters in dry places, the upper layers are under the full influence of the atmosphere. The decomposition of the fallen leaves and dead roots of the plants which grow here, the moss, &c., form, with the assistance of the atmosphere, an excellent kind of soil. Such moor and peat soils are so much the better for plant culture the higher the layers are formed above the moist sub-soil, and in consequence are looser in texture. When peat soil is taken from a wet place, it should be placed in a heap and allowed to lie for a year exposed to the atmosphere, in order to remove the sourness which it contains.

Any plants growing in this turf are allowed to remain, and it is not used until these, along with their roots, are in a great measure decayed. Soil of this kind, which is often improperly named heath soil, is mostly used mixed with clean sand.

The black or brown, fine, powdery, completely decayed moor and peat soil, such as is found in large masses in dry places, being too poor in nutritious matters, cannot be employed in culture by itself, or even when mixed with sand. When mixed with loam it is somewhat better, but it is much inferior to the looser moor and peat soil composed of vegetable matter in a less decomposed state.

Lastly, we small mention a kind of humus soil which is found in a state of fine powder mixed with pieces of not yet decayed wood inside of hollow trees. This is called wood soil or tree soil. It is still less nutritious than the powdery peat soil, and is only used in the culture of Orchids, Rhododendrons, &c. The best is found in oak trees, containing many pieces of decayed wood.

In the north of Italy wood soil obtained from the edible chestnut tree is used in the cultivation of camellias.

The most suitable kind of humus soil for plant culture is

that which contains a large quantity of undecayed roots and other matters. This even when it has lain for a long time in a heap, will contain many lumps or large pieces. These should be broken or chopped up with a hatchet and passed through an iron sieve with meshes about an inch wide. The coarser pieces which will not pass through should be grated against the sieve with the hand. The particles which will pass through a fine sieve should be rejected, and none but the coarser part, which contains the best properties of the soil, should be retained for use. Soil procured from woods should be treated in the same manner. Ordinary loamy soil, not containing roots, should on the other hand, be passed through finer sieves. This should be especially done with pure loam, which is to be used for mixing with humus soil.—*Dr. Regel.*

(To be continued.)

WINDOW GARDENING.

If there is one aspect of London gardening that may be appropriately termed badly done, as a general rule, it is that of outside window boxes. Hundreds of attempts are made at window gardening annually within the metropolitan districts, and yet but few of them can be said to be successes. This arises from, first, unsuitability of the plants employed; and, second, neglect. It is not unusual to see early in March, when cold northerly or easterly blasts prevail, window-boxes filled with tender plants from a warm house, such as cinerarias, primulas, and similar things, that in a day or two become shrivelled and browned. This is often attributed to want of water, and a copious supply being given soon completes the work of destruction. On the other hand, many a box of plants fully exposed to scorching sunshine and the drying effects of east wind, soon presents a starved appearance for want of water. There are, however, many exceptions, where a genuine love for plants causes them to be tenderly watched; and their wants supplied. Under such circumstances, they are a constant source of gratification.

My sitting-room window has an aspect due south, and on the outside of it there is a wooden box painted green, about forty-five inches in length by seven in width. In November last this box was planted as follows. At the bottom was laid some strips of green turf, and on this was laid soil, of which rotten manure formed a large proportion, about three inches in depth. On this I planted a dozen single Hyacinths, some of the best cheap varieties of different shades of colour, and about half-a-dozen bulbs of Narcissus *tazetta* (*Polyanthus Narcissi*). Then, having covered these with a layer of soil, I added another of bulbs, consisting of Snowdrops, *Crocus susianus* (*Cloth of Gold*), *C. biflorus* (*Scotch*), and some striped and blue varieties of *C. vernus*—only a few of each; with these I mingled a few roots of mixed Turban Ranunculus, covered the whole with soil, and then by way of a finish I planted along the front of the box some tufts of the pretty new *Leptosiphon roseus*. From the early days of February, when the Snowdrops and Early Crocuses come into bloom, and on down to the present time, when the gay flowers of the ranunculuses are fading away, and the tufts of the Leptosiphon are in full splendour, there has been one uninterrupted sequence of floral beauty. The Crocuses and Snowdrops died away gradually; but after the Hyacinths and Narcissi were out of bloom, I cut them down nearly to the surface, in order that the fast developing Ranunculuses might have ample space. While the bright, hot, dry weather lasted, I water copiously every day, though the soil in the box is so honey-combed by the number of roots it contains, that it passes through it very quickly.

In a few days the contents of the box will be turned out, and all the bulbs, with some soil adhering to their roots, will be carefully put away in paper-bags, for use in the same way next autumn. They will answer well two years in succession. Then the box being filled with fresh soil, will be again planted, with a few foliated and flowering plants. Over the front of it will fall the variegated form of *Sedum Sieboldii*, variegated ivy-leaved Pelargoniums, and the pretty pale lavender-blue *Convolvulus manitonicus*. A plant or two of a free-blooming *Tropaeolum Lobbianum*, Mrs. Pollock variegated Pelargonium, and similar things, will complete the arrangement till the end of October; and when they come to an end, another season for planting will have come round again.

Thus managed, the window garden is always gay and always attractive; and these simple and inexpensive modes of embellishment are capable of much variation. There is always procurable many subjects, hardy and durable, that can be employed to serve such a purpose as this during the winter and spring months. I have used *Iberis coriifolia* in this box, for instance, with surprising effect; early-blooming pansies, double daisies, *Phloxes verna*,

frondosa, and *Nelsoni*; and many others, of which these are fitting types, may also be employed. A few dwarf evergreens can be used during winter and early spring, to be succeeded by flowering and foliated plants for summer and autumn. Only let there be the desire to do something, and means will be found close at hand to effect the object in view. In the grandeur of our conceptions of horticultural enterprise, and in the lofty ideas of gardening prevalent nowadays, we are apt to lose sight of the value of simple things, which though unpretentious, are often highly praiseworthy and effective.

Quo.

THE ARBORETUM.

NORFOLK ISLAND PINE IN THE SYDNEY BOTANIC GARDENS.

We all know this graceful Pine in our conservatories both in public and private gardens, but few have an idea of its great stature and beauty in its native isle. Our friend, Mr. C. Moore, director of the Sydney Botanic Garden, has, however, shown what it is capable of becoming in New South Wales, and we have much pleasure in giving a representation of the trees therein. The tree differs in habit from most of the Pines known to us. It will probably prove a noble ornamental tree over vast regions in temperate countries, as, for example, in California, Southern Europe, Egypt, and other countries with warm, temperate, and sunny climates. Although its native home is amid the sea breezes of the Southern ocean, there are few plants that thrive better in living-rooms in England. We have noticed small trees of it thriving year after year in London sitting-rooms.

THE REGENERATION OF ALPINE FOREST LAND.

Much has been written and said of late years, says the *Pall Mall Gazette*, respecting the deterioration of soil and climate in regions where the neglect of an ignorant and selfish population has allowed vegetation to perish without duly replacing it. A good deal of the discussion has been premature: the whole question of the effects of forests in promoting rainfall is as yet entirely uncertain, notwithstanding the peremptory and exaggerated tone in which it has been and is continually asserted. It is an unsolved problem treated by superficial observers as an axiom. In France, where the subject has been more closely treated than among ourselves, opinion is gradually undergoing a change respecting it. Fact and theory are alike disputed. No proof has certainly been given that, in temperate climates, at all events, a hundred acres of forest attract more rain than a hundred acres of turnips. And no philosophical reason has been advanced why they should. But, uncertain as it is whether forests attract rain, it is beyond all doubt that they store and preserve it; they check the evaporation of the surface water; they also regulate and retard its descent down the slopes of the hills; they serve, therefore, as a safeguard both against drought and floods. But, in order to reproduce fertility on mountain sides which have been denuded and devastated, the replanting of forests, although the best, is not a necessary expedient. "Gazonnement," as the French term it—the covering large surfaces with fresh turf, carefully fenced and tended until it consolidates—seems to be attended with at least an approach to the same beneficial effects. There is an interesting paper by M. H. Blerzy in the *Revue des Deux Mondes*, in which the effect of this experiment in the French department of the High Alps is detailed. This district has been for some centuries gradually rendered desolate by the wasteful neglect of which we have spoken. It has an extreme climate—Mediterranean heat alternating with Alpine frosts, persistent drought with violent storms; all the rain and snow of the year sometimes falling in less than three weeks. Bit by bit its forests have been improvidently destroyed, until only a few patches (comparatively speaking) are left. And their natural recovery is rendered impossible by the pasturing of sheep, and still more of goats, the only industry left to the peasant. Under these circumstances the slopes have become bleak and bare, the valley bottoms mere accumulations of sand and pebbles. Year after year mountain villages are abandoned and the population driven to emigrate. In twenty years only—from 1846 to 1866—the population diminished by 11,000 inhabitants, or about one in fifteen.

Such was the state of things when what M. Blerzy terms—we hope not too confidently—the "regeneration" of these mountains began under the Forest Law of 1860: applicable to the mountain districts of the whole of France, but of special utility only on certain portions

of their surface. This law rendered "reboisement," replantation, compulsory only in cases where the denuded condition of the soil rendered it a cause of damage or danger to the neighbourhood; it required a careful multiplication of preliminary inquiries and consents; it allowed of the plantation of not more than one-twentieth of the surface of a commune in a single year; it respected, in short, ever timidly not only the individual vested rights but what may be termed the collective prejudices of the peasantry. Modest, however, as it was, the measure could not fail to excite their selfish feelings and their fears, and nowhere more than among the old-fashioned and tenacious boors of the Alps. "With the exaggeration so natural in the peasant who fancies his property threatened, they compared the agents of the forest law to ogres ready to devour their flocks and their pastures." The Administration, instead of persisting with official obstinacy, adapted its proceedings in part to the popular feeling. In 1864 the law was amended by allowing the substitution of "gazonnement" for "reboisement" in cases where the agents did

to be regarded on all hands as the safeguard of the country, except by a few inveterate malecontents. "To regulate the pasturages, to plant the naked ravines, has become the pre-occupation of the country. . . . Slowly, but surely, the hideous gorges which scored the mountain sides disappear under verdure; in the low grounds, the cones of desertion" (mounds of loose stuff which invariably form at the point where an uncontrolled torrent reaches the plant) "become covered with crops and with groves; the beds of the stream are fixed; the bridges are no longer periodically carried away; the brooks which descend to the rivers become limpid instead of being loaded with gravel and sediment." But there is much more to be achieved. "These austere regions of the Alps, where man lives close to the limits of the habitable world and struggles against the terrors of nature, frost, drought, rain, torrent, are like a dilapidated house, which must be taken completely in hand if it is not to be suffered completely to perish. Population abandons them, national wealth diminishes in them day by day. . . . It is still a land to be reconquered, not from the enemy, which would be glorious, but from nature, which is more glorious still."

Perhaps the most satisfactory part of this little narrative is not the victory over nature which it celebrates, but the victory over prejudice. We are apt to despair too readily of winning over backward classes of people, such as the peasants of the higher Alps, to those benevolent efforts on their behalf which they do not fully understand or appreciate at once. Generally there is some foundation, though probably an inadequate one, for their opposition to novelties. In the present instance, it is plain that the country people had reason for fearing the immediate consequences of encroachment on their meadow-land by plantations, though to their and the country's ultimate benefit. But when the promoters of the experiment had the good sense to meet them half way—to modify the innovation by substituting in part artificial meadow for plantation—they were soon brought to see the whole proceeding in a different light, and to lend their aid to the general improvement, even though part of it would not result in their immediate gain.

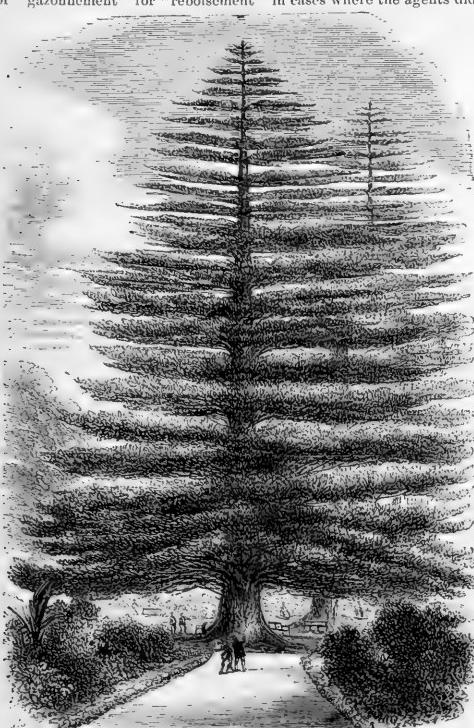

Silver Variegated Wild Olive.—While a large amount of admiration is bestowed by lovers of trees on the beautiful and varied tints and bright hues assumed by the foliage of many of them before they fall late in the autumn, I do not think that sufficient attention is paid to the extremely beautiful changes that take place in the foliage of some trees and shrubs at other seasons of the year. I have been led to this conclusion by observing this season for the first time a most beautiful change which took place in the leaves of a rather uncommon but extremely ornamental shrub—the silver variegated form of the Wild Olive (*Elaeagnus reflexus argenteo variegatus*), which I consider to be a much more desirable plant than the better known golden variegated form, from its much greater compactness of habit, as well as from the greater constancy and evenness of its variegation. Being an evergreen, the old leaves are displaced about the middle of May, or towards the end of that month, in each year by the young growth; but before falling off a large number of the old leaves undergo a most beautiful and remarkable change of colour, the pale glaucous green portions becoming almost pure white, and the silver variegated streaks and blotches changing to bright gold, giving the leaves an exceptionally beautiful appearance. Let me hope that this fact may induce all who are fond of beautiful hardy shrubs, and who do not yet possess the plant in question, to at once add it to their collection.—W. E. G., *Junior Carlton Club*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Contending Leaders.—Trees are often found either by accident or otherwise having more than one leading shoot, about which many ideas have been adduced, such as bending the contending ones down, cutting off their tops and the like. This is all very well if done when they first appear, but after they attain a foot or two in length, I find that the only sure remedy is to take the saw and cut them right out. It may disfigure the tree for a time, but they will soon recover. When the pressure of high winds are brought to bear on trees having more than one leader, a fracture is almost certain.—J. TAYLOR, *Margeryanne, Whitland, South Wales*.

Large Yew Trees.—There is a fine yew tree in Knockholt churchyard, the dimensions of which are as follows:—Height, 46 feet 7 inches; circumference of branches, 202 feet; spread of branches from north to south, 69 feet, and from east to west, 66 feet; girth of stem and sound stem, 22 feet; length of such stem, 10 feet 6 inches. The height and girth, this yew does not equal the one in Wiltshire, in the case of the Marquis of Bath, but every other particular it exceeds it.—*Rev. J. Hall, Knockholt Rectory, in "Standard."*

I send you the dimensions of a very tree growing in the grounds of the old castle at Crom, the residence of the Earl of Erne, in the county of Fermanagh, Ireland. Height, 25 feet; greatest girth of stem, 12 feet; length of stem, 6 feet; circumference of branches, 250 feet; sprout of branches from north to south, 77 feet; sprout of branches from east to west, 76 feet. Although separated from the first, a third of stem by the one mentioned in your correspondence, I doubt whether another with so large a spread of branches can be found. It is shaped like a huge mushroom, and is in a most healthy and flourishing condition. Its lower branches are interlaced with and grow into one another in a most remarkable manner.—C.

Norfolk Island Pine in the Sydney Botanic Gardens.

not consider plantation absolutely necessary. In such instances, says M. Blézy, trees and even shrubs can be dispensed with; turf only is required to reconsolidate the soil, on condition that the sheep are restrained from eating the grass down to the root. "On the slopes which the flow of water has not as yet wholly denuded, the smallest patch of vegetation, a simple tuft of grass, suffices to retard the waste of rain water and to distribute it, preserves the freshness of the soil to the advantage of vegetation itself, and detains the pebbles from rolling down the slope. The result is obtained without restricting the peasant's area of pastureage from which he derives his living."

And it is remarkable and very satisfactory, if our author can be relied on, that not only has the recovery of the soil been aided by this judicious experiment, though as yet only in its infancy, but that it has had a great effect in softening down the prejudices of the people, and thus smoothing the way for greater improvements. The "mise en réserve" of successive portions of the meadow land, at first protested against and even resisted with violence, has begun

THE KITCHEN GARDEN.

PLANTATIONS OF ASPARAGUS.

RELATIVE SUCCESS WITH PLANTS OF ONE, TWO, AND THREE YEARS OLD.

THERE are still many who think that by planting roots two or three years old they will gather Asparagus sooner than if they plant those which are but one year old. To disabuse them of this idea, I shall bring before them the result of several experiments which I have made. I planted (No. 1) twelve roots of a year old (No. 2), twelve of two years old, and (No. 3) twelve of three years old. The results were as follows:—

First Year.—Of No. 1 all had made growth before May 4th, and the vegetation was fine; No. 2, ten plants started before May 4th, one on the 10th, and the other failed. The shoots were a little stronger than those of No. 1. No. 3, eight plants started before May 4th, one on May 12th, and the other three failed; and, although at first the shoots looked well, afterwards declined, and on September 15th they were feebler than those of No. 2.

Second Year.—No. 1, fine vegetation; shoots strong and regular on the 15th of September. No. 2, good growth; shoots irregular, and a little feebler than those of No. 1. No. 3, growth mediocre; shoots very irregular, some roots having eight or ten, but all feeble; another plant died after having produced two stems.

Third year.—No. 1, growth magnificent; stems measuring on the 10th of May from 2 inches to 3½ inches in circumference. No. 2 growth passable, but irregular; some tufts small and weak; the finest had shoots on the 10th of May not more than 2½ inches in circumference. No. 3, growth very middling and irregular; some tufts gave off shoots no bigger than quills, and the best reached little beyond 1½ inch in circumference.

Fourth year.—No. 1, growth remarkable; the shoots appeared from the third to the 10th of April, some as many as 4 inches in circumference; they afforded fifty shoots, which formed a bunch weighing more than 6 lb. No. 2, growth passable, but a little later than that of No. 1, and with plenty of small shoots; fifty made a half bunch, weighing little more than the half of that cut from No. 1. No. 3, vegetation poor, one plant not starting till the 22nd of April; fifty shoots formed only half a bunch, and did not weigh more than 2½ lb.

To resume, it will have been seen that the plantation formed with plants a year old has given at its fourth starting, or at the end of three years of plantation, a bunch of Asparagus twice as large as that of either of the others. In other terms, the plantation made with plants a year old, produced double that of the one where two-year-old plants were used, and nearly treble that made with plants of three years old.

V. F. L.

Keeping Celery.—The following mode, which we have tried thoroughly, may be worth remembrance at the proper season:—Our plants were grown last year in the usual way, but not blanched. About the middle of November, a trench a foot and a half deep, or just deep enough to take in the plants when set upright, was dug in a hollow which had perfect under-drainage, and the plants then carefully lifted out of the soil in which they grew, the earth shaken from the roots, and they were placed upright in the trench as closely as they could be conveniently packed. The earth was then drawn against the sides along the trench, and the top covered with a stratum of dry leaves a foot thick. A few inches only of leaves were first applied, but as the cold weather of December came on, more leaves were added. Being in a hollow, the wind did not blow the leaves off, while the snow drifting on, added to the protection. Towards spring the stems were perfectly blanched, and there was not the slightest difficulty in procuring a supply at any time by merely lifting off the leaves—vastly easier than to remove frozen earth. Finer celery is not often seen. Those who have no similar depression in the ground may dig a foot deeper than otherwise, lay a tile in the bottom for perfect drainage, put in the plants, and then there will be a foot left to fill with leaves. Lay on a few evergreen boughs to keep any of the leaves from blowing away.—*Albany Cultivator.*

Green Maize or Indian Corn.—This is almost an unknown delicacy in England, that is, when the cobs, as they are called in America, are still green, and have the grain full of milk. The ear should then be stripped off the stalk and boiled for about twenty minutes. The cobs should be brought to table whole, and eaten with butter and salt. The only variety that I am sure will ripen in England is that called "Galatz," and nothing can be cultivated with greater ease. The grain should be sown in May, about a couple of inches deep along little drills about two feet apart, and the plants

should stand one foot apart in the drills. As the plants advance to about the height of a foot a little earth should be drawn up about the stems. When the plants have grown about two feet high digging between the rows should take place, and the stems of the plants should again be earthed up three or four inches. After this there is nothing to do but to keep the ground clear from weeds. About the latter end of July the corn will be in bloom, and the cobs of corn will begin to show themselves, and about the latter end of August there will be some corn ready for the table; and as some of the cobs will always be in a less advanced state than others, there will always be some ready to pull until about the end of September. The cobs that are left until October, will, if the season is favourable, become ripe and the grain hard. Two or three of the best should then be saved for seed. The common plea urged against the cultivation of maize in this country is, that it will not ripen in wet seasons, but when I assert that I have for the last four years grown and ripened the above-mentioned variety, and that I have now in my ground, which is situated thirty miles west of London, seed saved from last year's crop, and which is all germinating, I think I have sufficiently proved that one variety of maize at least will come to perfection in the south of England, however unfavourable the season.—K. F.

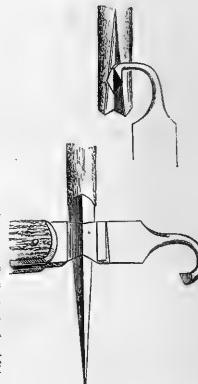

THE PROPAGATOR.

THE ART OF GRAFTING.

(Continued from p. 676.)

GRAFTING BY INLAYING.

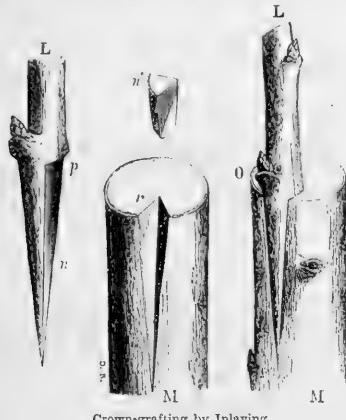

GENERAL DIRECTIONS.—Formerly known under the name of grafting *à la Pontoise*, this method was employed specially for the propagation of the orange tree and certain shrubs; at the present day it is applied to a greater number of plants. The establishment of Simon-Louis, at Metz, has extended its use to almost all kinds of trees and shrubs. The principle of the operation is to inlay the scion, which is cut with a triangular face, in the stock so as to thoroughly exclude the air. The proper seasons are in spring, when the sap begins to flow (although one may also graft in summer, using semi-herbaceous scions), and in August and September with woody scions. The time to be preferred is about the end of March and in April. The stock is prepared beforehand, or at the time of grafting, so that the scion may be placed on a fresh cut. For spring-grafting the scion-branches are cut in winter and kept in soil or sand in a shady place. It will also answer to cut them from the parent-tree a few days before grafting. In summer-grafting they should not be cut until immediately before they are wanted. The scion, which should have two or three eyes, is cut at the lower part with a wedge-like or triangular face, and is laid upon the stock in an angular groove, corresponding to the triangular face of the scion. It is then bandaged, and the cuts are covered with grafting-wax. The preliminary operations are performed with a fine-edged pruning-knife and the ordinary grafting-knife; but greater rapidity and precision are secured by the use of the combined grafting-knife. Both ends of the tool are sharpened and set at the same angle, which gives a mathematical accuracy to the operation. It is immaterial whether the angle be rectilinear or curvilinear; the essential point is that it be identical in both parts of the implement. With common tools a groove with a blunt or a square outline is often made; or it may have the contour of a trapezium, or any other figure; the only really important thing being that the scion be cut to fit it accurately. Grafting by inlaying is performed on the crown

Inlaying with the combined grafting-knife.

of an amputated stock, and sometimes on the side of a stock not amputated.

CROWN-GRAFTING BY INLAYING.—Suppose first that we have not got a combined grafting-knife. The scion (*L*) is cut with a triangular face (*n*), of which a section is given at *n'*. The notch (*p*) will serve as a shoulder to rest the scion on the head of the stock. The scion is then placed with the back of the triangular face against the stock (*M*), and the outline of it marked with the blade of a knife. The bark and wood are then cut away so as to form a wedge-shaped groove (*r*). The scion (*L*) is then laid in the groove made in the stock (*M*) as shown at *o*. The operation is completed by applying the bandage and grafting-wax. It may be easily understood that the use of the combined grafting-knife will save all delay and

Crown-grafting by Inlaying.

uncertainty; and when a little dexterity is acquired in handling it, the operation of inlaying can be performed with great rapidity.

SIDE-GRAFTING BY INLAYING.—This method is not so much employed as the preceding, because veneering, which resembles it very much, is far easier. Branches with knees or curves may be laid in on a straight stem in the same way as a straight scion is grafted on a bent stem. Thus inlaid, the scion will possess greater firmness than if attached by veneering, especially if the stem of the stock be so rugged as to render the adjustment of the parts difficult.

TREATMENT AFTER INLAYING.—Should the scion be insufficiently secured on the stock, it should be bandaged firmly, using a broad rather than a narrow bandage, as less likely to become too tight. The immediate and continuous employment of a prop or stake, to which the graft is fastened, should not be neglected. Unless they are specially required, the pinching of the young shoots of the graft will accelerate the cohesion of the parts, as thereby a smaller surface is exposed to the action of high winds. In other respects, the treatment will be similar to that which we have directed in the case of ordinary side-grafting.—*C. Battel.*

(To be continued.)

Durability of Framed Timbers.—The durability of the framed timbers of buildings is very considerable. The trusses of the old part of the roof of the Basilica of St. Paul, at Rome, were framed in 816, and were sound and good in 1814, a space of nearly a thousand years. These trusses are of fir. The timber-work of the external domes of the Church of St. Mark, at Venice, is more than 810 years old, and is still in a good state. And Alberti observes the gates of cypress to the Church of St. Peter, at Rome, to be whole and sound after being up nearly 600 years. The inner roof of the Chapel of St. Nicholas, King's Lynn, Norfolk, is of oak, and was constructed about 500 years ago. Daviller states, as an instance of the durability of fir, that the large dormitory of the Jacobins' Convent, at Paris, had been executed in fir, and lasted 400 years.

OUR COUNTRY CHURCHYARDS.

Why rural churchyards should invariably have such an uninviting look about them is one of those things which I am unable to understand. If there are any special spots in our parishes where we might expect due regard paid to decency and order, surely they should be our graveyards. I hold, contrary to custom though it be, the practice of making a mound on the top of every grave a mistake, and one of the prime causes of that disorder which is so prevalent in country churchyards. Surely, we would sleep as soundly under the turf of a smooth level lawn as under an uneven surface; and the proper keeping of a flat graveyard would be easy compared with that of an uneven one. Perhaps, however, the entire absence of any system in the laying out of graveyards has not a little to do with their uncouth appearance. Niggardliness in the space set apart for the burial of the dead is one great characteristic of our rural parishes; and thus, space being prescribed, the possibility of making a few nice walks and the planting of a few fitting trees and shrubs becomes a matter of grave doubt, if not of comparative indifference. Of course these are defects that cannot well be

remedied in connection with churchyards already in existence; but where new ones are being established it becomes a question worthy of consideration as to whether a sufficiency of space should not at once be obtained, so as to admit of some effect being produced by laying the ground out in such a manner that the gardenesque, so to speak, is not entirely swallowed up for convenience sake or for the sordid anxiety of making the very utmost of the space allotted for burials. Paths should be first formed, then planting of suitable trees should follow, and these should mainly consist of weeping trees, because the habit of growth they display seems to consort best with the character of the place, without giving that heavy, monotonous, lugubrious appearance that arises where trees of the *Pinus* tribe are wholly used. Flowering trees especially should be planted, such as the coloured thorns, snowy *Mespilus*, double-blossomed in cherry, and the almond. Soft colours, or whites, should be selected, but not yellows, such as the laburnum, as that would be out of place. For foliage trees, few are so fitting for planting in a burial-ground, and perhaps so seldom used, as the purple beech, added to which, by way of pleasing contrast, should be the variegated *Acer Negundo*; these being toned down with the weeping ash, birch, elm, and other trees of graceful outline. These, with a few others carefully selected, would afford a pleasing variety. Any shrubs employed should be evergreen, or such as could lend additional charm by early blooming. Variegated hollies, *Aucubas*, *Euonymuses*, &c., interspersed with some rich greens of *Buxus*, *Portugal laurels*, and bushy-growing *Pinuses*, would at all times furnish the bare sward without adding dullness or density.

No one can do justice to such a question as this without taking into consideration that love for flowers abounds the abodes of the dead that so strongly characterises many of our poorer neighbours. In Roman Catholic countries the laying of floral crosses and immortelles upon the graves of deceased relatives is a practice honoured in the observance. With us, it is slowly, but gradually, acquiring force; there is, however, something almost ludicrous in the appearance of these designs in flowers, lying amidst the long grass, looking, after a warm day, so utterly wretched and woebegone. Nevertheless, one may perceive, even in this humble attempt at decoration, something of purity in the desire, although the conception is so replete with poverty. If we dispense with mounds, and have merely a level even surface in our churchyards, and if, moreover, they were placed under due superintendence, small flower plots could be made which might be effectively planted, so as to render churchyards pleasant and cheerful, rather than places to be avoided, as being only suggestive of gloom and death. Could anything in the way of decoration of graves be prettier than having their shapes marked out in the green sward by a margin of snowdrops, inside of which might be a small cross of white crocuses? or if a bed be desired, what would be neater for winter and spring than a slightly raised edging of *Sedum glaucum*, a carpet of *S. acre aureum*, and a cross of *Sempervivum metallicum*? In the spring also pretty designs might be worked out by means of various coloured double daisies, white and blue *Violas* and pansies, lilacs, *Aubrietas*, variegated *Arabis*, and many other dwarf hardy plants that are familiar in our spring gardens. In summer, neat dwarf-growing plants that create no violent contrasts should be used; and for centre purposes few plants of modern introduction convey a more fitting conception of melancholy than does the drooping *Amaranthus salicifolius*.

Such arrangements as these could not fail to improve the appearance of our rural graveyards. Ofttimes when I walk by my own parish church, and look upon the rough tumble-down fence that encloses its graveyard, when I look upon the long coarse grass, the rugged, uneven surface, the forlorn-looking over-grown trees, and other appearances that denote rather the sluggard's garden than the habitation of departed friends, I feel that our mourning and sorrow, as a rule, begin and end with the closing of the grave. I do not want to see the use of flowers made general in our graveyards because superstition thereto lends its approval; what I desire is to have not less sweet and beautiful our places of eternal rest than our gardens of pleasure. I for one, therefore, earnestly hope that the present disgraceful appearance of too many of our churchyards may soon become a thing of the past.

A. D.

LAW NOTES.

—THOMAS PENFOLD, aged ten, was charged the other day with stealing a bunch of flowers from a garden in the occupation of Mr. Dunkerton, on the Round Hill estate, Leeds. The flowers—pinks—were pulled up by the roots; and prosecutor, who said he had no wish to punish the child, said he suffered great loss from boys committing frequent depredations in his garden. The father of prisoner gave the boy a good character, stating that he was kept at school, but the boys had got a fortnight's holiday

As prosecutor did not press the case, the Bench sentenced prisoner to a day's imprisonment, remarking that stealing growing things from a garden was punishable by six months' hard labour.

—At Marlborough Street, four boys were charged with damaging the geranium plants in Hyde Park. One of the park-gardeners said the flower-beds were much robbed, four dozen plants having been taken in one night. The boys said they only took one flower each, but the constable said at least seven plants had been damaged. The magistrate said the parks were kept up at great expense for the benefit of the public, and such conduct as that of the prisoners was too bad, for if it was allowed there would soon be nothing left. The boys would have to pay twenty shillings or fourteen days.

—WILLIAM SMITH, an office boy, was lately charged at the Wandsworth police court, with stealing roses from Battersea Park, the property of her Majesty's Commissioner of Works. Mr. Ingram fined him 5s., in addition to the value of the roses.

—AN old man, formerly Lord Byron's gardener at Newstead, and now officiating in that capacity in Golden Square, was brought before the magistrates the other day for killing cats. The case was taken up by the Society for the Prevention of Cruelty to Animals, and the man was sentenced, at Marlborough Street, to a month's imprisonment. He appealed, however, against the conviction, and it was quashed. Some of the papers commented on the matter, and the result was that actions were commenced against two. That against the proprietor of *Fun* was heard in the Court of Queen's Bench last week, and resulted in a verdict for the defendant. The order against the printer of the *Daily Telegraph* was withdrawn. In the course of the evidence it was deposed that the plaintiff began beating at twelve o'clock, and "something moved in the sack in which the cats were put at a quarter to one." The defence set up by the gardener was that he had been a gamekeeper, and adopted this as the quickest method of destroying animals.

OBITUARY.

MARSHAL VAILLANT died on the 4th instant at his residence, Rue des Varennes, Paris, aged eighty-one years. He was born at Dijon, of very poor parents, and it was by his diligence and perseverance that he attained the high position he held. Although he belonged to the official world, and for some time was a prominent member of the Government, he was never what could be called a politician; he was fond of natural history, with which he chiefly occupied himself, but, above all, horticulture. He was for some time president of the Central Society of Horticulture of France, and as such acquitted himself well, nearly always attending its meetings, and often taking part in the discussions. He took much pleasure in the cultivation of plants, of which he has made known many interesting details, revealed to him by experience on his property in the Bois de Vincennes. Notwithstanding his severe mien, he was kind-hearted, simple, and ever happy to oblige.

MR. GEORGE LIGHTBODY, of Falkirk, died on the 9th instant. As a raiser and cultivator of auriculas and tulips, Mr. Lightbody obtained a high and well-deserved reputation. The auricula was, however, his specialty—not for a short time, but for nearly fifty years. Richard Headly, named after his old and sincere friend, Mr. Headly, of Cambridge, is probably the best auricula grown. Fairy Queen, Star of Bethlehem, Alma, Robert Trail, Sir Charles Napier, Sir R. Peel, Countess of Dunmore, Fair Flora, Fair Maid, Lord Clyde, and Meteor Flag, all of fine quality, and still grown in our best collections, are also the productions of Mr. Lightbody.

We also regret to have to announce the decease, on the 14th instant, of Mr. Joseph Saltmarsh, senior partner in the firm of Saltmarsh & Son of the Moulsham Nurseries, Chelmsford.

ANGELS' EYES.
(GERMANDER SPEEDWELL.)

RAMBLING along a bowery lane,
A little child I chanced to meet,
Whose pinnafore and hands were full
Of wild flowers—bright and sweet.
Around her hat a wreath was twined
Of blossoms, blue as southern skies;
I asked their name, and she replied,
"We call them Angel's Eyes."

A pretty thought, and one that must
Have been inspired by love—
That angel's eyes look from the earth
As well as from above.

I watched the flower-decked maiden pass,
And, wandering on, I sought
Those starlike flowers among the grass,
Whose name had stirred my thought.
These blossoms upward seem to glance—
And with that glance pure thoughts arise
From earth toward heaven; led above
By those blue "Angel's Eyes."

—MRS. T. S. JERROLD.

SOCIETIES, EXHIBITIONS, &c.

ROYAL HORTICULTURAL SOCIETY'S GREAT EXHIBITION AT BIRMINGHAM.

(JUNE 25TH TO 29TH.)

It was pleasant to see a great centre of industry like Birmingham proclaiming a general holiday, and putting itself in *costume de fête* to inaugurate a public display of flowers, as it did on this occasion. There was a time, and not a distant one, when it required a sanguinary battle, and the wholesale slaughter of some thousands of our Continental neighbours, to excite such an enthusiastic display of banners. Over the lofty granite pediment of the Town Hall, the Royal Standard flaunted the golden lions of England, the red lion of Scotland, and the harp of Ireland, to the gay buffeting of the summer breeze; and who shall say that one of the town councillors of Radical Birmingham did not rush off by "express" to London, to secure a larger and more splendid banner than ever waved above the great Birmingham hall before? Whether that was so or not, the great flag, thirty feet long by sixteen feet broad, bore itself right royally on the stout flagstaff, and formed a grand festal object from many points of view. Our English colours, whether in the form of the great war banner (our island's "Oriflamme") or in that of the Union Jack, floated from every steeple, either singly or in groups—but more generally half a dozen at a time: they don't do things by halves in Birmingham. The private houses, too, along all the principal streets were clothed in a riotous suit of waving flags, making veritable avenues of rustling bunting, almost as dense as that of the Strand on the memorable Thanksgiving Day. Among the banners none struck us as more characteristic than that hung out by a shoemaker on Snow Hill. "Nothing like leather," said the cobbler—and in that feeling the shoemaker composed his banner of three skins of prime morocco, embodying the colours of the Union Jack—red, white, and blue.

The great provincial shows of the Royal Horticultural Society have proved the most successful step taken by that body for many years; and the great exhibition now over is justly considered the most successful show that has yet been held in the provinces. Flower shows have almost become as common as market days; so plentiful, indeed, that for many of their once enthusiastic admirers they have now lost their charms. But this great yearly show seems to possess an interest and a freshness which is quite lacking in the other shows of the year. The shifting of the ground each year to some great centre of industry, and consequently of gardening, is the main element of success. So far as anything in the shape of public gardens, parks, or squares are concerned, there is probably no city in any highly-civilized part of the world so poor as Birmingham; and considering its wealth there is scarcely one in which there is so little that is remarkable in gardening, so far as private establishments are concerned. Smoke, very dense and disagreeable, may be answerable for some of this; but not all. We hope, therefore, that this noble show of the products of the garden may prove a stimulus to gardening progress in that neighbourhood, as well as a most instructive and agreeable sight to the many thousands of strangers who poured into Birmingham from all parts.

The show, it is scarcely necessary to remark, took place in part of the grounds belonging to Mr. Quilter, whose gardens are the most famous in the district, both for spring and summer bedding plants. Its most remarkable features were the very extensive exhibitions of implements, boilers, &c., the fine series of glasshouses, the numerous exhibitions of dinner-table decorations, the large and varied collections of plants, many of them being admirable examples of high culture; the fruit and vegetables, the numerous graceful young conifers, and other evergreens shown in various parts of the ground, both planted out and in baskets or tubs; and Mr. Quilter's spring flowers and gardens generally; and, last, but not least, the seas of mud which the heavy rains of the past week have left both on tent on lawn.

The exhibition, which was opened by H.R.H. Prince Arthur, last Tuesday at noon, had great advantage in being held on grounds adjoining a very pleasant garden; in fact, we doubt if anything in the show proper struck people so much as the last aspects of beauty presented by Mr. Quilter's spring flowers in a walled enclosure, which, like all the rest of his grounds, was open to those who visited the great show.

TABLE DECORATIONS.

THESE were, according to arrangement, exhibited by gaslight, and the effect on the whole was excellent. It was, however, evident that the simpler the arrangements were the more successful was the result, and that where moss and ferns, notwithstanding the intermingled flowers, covered up too much of the snowy table-cloth, the decorations, which ought only to be supplemental embellishments to a

dinner-table, seemed struggling to occupy the first place instead of the second. This principle, when found, "take note of," as the renowned Captain Catto remarked, for it is an important one; and it cannot be too strongly impressed that in decorating a dinner-table we have too much of grasses and ferns and mosses, however elegant they may be. We must not impart to an elegant repast, with its shining silver, snowy linen, costly china, and other indoor appurtenances, a too rustic aspect, and transform it in appearance into a pic-nic on the grass, among real growing mosses and ferns. One of the great principles of decorative art is suiting the form to the purpose; and the second is, the relative proportions of repose and decoration, both of which are sometimes sadly outraged in arrangements of the kind under discussion. But we must begin, *seriatim*, the description of the ten decorated dinner-tables, which had been prepared for competition.

Table No. 1 was decorated by the tasteful hand of Mr. Müller, of Vienna. The central object was a three-tier glass epergne; the saucer from which the main glass stem rose was filled with two graceful kinds of ferns, from among which nestled five or six of the resplendent scarlet flowers of *Cereus speciosissimus*, which have a very rich effect among the green. The tier above was filled with white *Fuchsias*, which drooped very prettily over the glass rim, and the upper tier was crowned with a circlet of single flowers of a white, mauve-marked *Gloxinia*, from which arose a graceful slender tuft of the ever elegant ribbon grass and a spray or two of the maiden-hair fern. The two secondary vases had a vine spray twined round the slender glass stem, and in the tazzas were some fine *Petunias*, heightened in effect by ferns. The dishes of fruit were neatly relieved with a few touches of greenery, and round the table were small vases with button-hole bouquets. This decoration was awarded the fourth prize.

Table No. 2, furnished by Mr. Perkins, of Leamington, struck us as being very pleasing. The tall glass stem of the central vase was left entirely bare, and with good effect. The upper tazza was furnished with drooping *Dicentra*, and branches of red *Fuchsias* with double white corolla, peeping out of a light crest of ferns, from among which straggled gracefully upwards, a branch of one of the many-flowered yellow *Oncidiums*. At the base, two small plants of the elegant *Arca rubra* sprang from a bed of moss, and then came, alternately, lying luxuriantly among delicate ferns, large water-lily flowers and starry flower-like plants of *Echeveria*, which looked like water lilies of leaves instead of petals. The happy contrast was well conceived, and if the *Echeveria* had not been procurable, an analogous effect might have been produced by a star of the common houseleek. Two dark Damask roses imparted power and richness to this little composition. The two secondary vases were treated in a similar manner in the upper tazza; but in the sincer, instead of the *Echeveria*, fine Bourbon roses lay snugly among the moss and ferns. The other features of the table were not remarkable, but very pretty; especially the small button-hole bouquets. We felt disappointed that this table did not obtain a prize.

Table No. 3 was shown by Mr. H. Vertegans, of Chad Valley, near Birmingham. The central epergne was of three tiers. The two lower ones, saucer-formed, were filled with various fruits, which were, however, not as artistically arranged as they might have been. Fruits, grouped with taste and judgment, and well contrasted in form and character, are as capable of being formed into pleasing and graceful groups as flowers, as we know full well from the beautiful compositions of the great fruit and flower painters, from Van Huysum to the present hour. The upper tazza had for its principal feature a handsome *Tea Rose*, which, with brackets of *Spiraea japonica* and light fern fronds, made a handsome crown enough. The minor features of the table were kept entirely green; sprays of graceful plants sprung out of little mossy beds, just scantly starred with a few small flowers. This effect of nearly all green, was cool, fresh, and pretty. But it was overdone; there was too much of moss, and fern, and grass.

Table No. 4.—The floral embellishments of this pretty contribution were devised and manipulated by Mr. Chard, gardener to Sir F. Bathurst. Lightness and elegance had evidently been the chief object in this sample of table decoration. From the upper tazza of the glass epergne rose the feathery ramifications of grass flowers, of the lightest and most fairy-like kind, mixed with a spray or two of meadow sweet, and from the centre rose a couple of spikes of the common crimson cornflag; quaking grass trembled in the vases of the side branches, mixed with a few flowers of the delicate *Deutzia gracilis*. The small button-hole bouquets in small vases at the place of each supposed guest, consisted simply of various kinds of half-expanded roses, accompanied by a scrap of fern or some other pretty leaf.

Table No. 5.—Miss A. Hassard.—The central object was not, in this composition, a tall glass vase with flowers and ferns, but a single complete plant—very pretty and palm-like, with drooping leaves, probably *Areca Verschaffeltii*. It sprang from a large glass saucer, in which were ferns and water lilies. The two secondary objects were glass tazzas, raised on slender twisted stems. The tazzas contained grasses and a few well selected flowers. Between them and the central object were two pretty blade-leaved plants, which appeared to have grown through the table-cloth. They were fixed to it in some artificial manner—they did not, however, seem to be wanted there—their *raison d'être* was not sufficiently apparent.

Table No. 6.—Decorated by Miss E. Blair, of Upper Bedford Place, Russell Square, London.—The central epergne in this was formed of five curved and slightly divergent trumpet-shaped vases. These contained

only delicate flowers, grasses, and ferns. In the saucer forming the base, were some well-disposed fronds of the finer variegated ferns, between which were water lilies. The most distinctive feature of this decoration consisted of two pretty statuettes in Carrara marble. They were reclining figures, the one a miniature of Bailey's well-known "Eve at the Fountain," the other, a group of two figures in a corresponding position. Had these been standing inside of reclining figures, they would have been less effective, their slight elevation forming a far better contrast to the tall vases. The figures were brought gently into the floral composition by making them repose upon couches of delicate fern, starred with a few small white blossoms and by a few graceful sprays, which, as they swayed over them, added to their beauty by contrasting with the pale cream-coloured material of which they were composed, yet so sparingly as not to break or conceal a single important outline. This pretty sample of table-dressing received the second prize.

Table 7.—Dressed by Mr. H. Cole, of Birchfield, near Birmingham.—In this there was a tall central glass vase, filled with choice blooms of Pelargoniums, mingling very prettily with a plume of feathery grasses; depending from the upper tazza was a long spray of dark and richly variegated leaves, which ought to have had a graceful effect, but somehow it was rather a blemish than a beauty in the composition. Water lilies and Cactus flowers enriched the moss and ferns of the saucer; the side pieces had maidenhair fern mixed with delicate sprays of variegated leaves, but no flowers. The effect was chaste and pretty. This table received the third prize.

Table No. 8, furnished by Mr. D. Cole, of Birmingham, was distinct in character from all the others, in consequence of the different style of the central epergne, and the supports of all the other vases, large and small. These vases, of elegant Grecian design, very severe and chaste in character, were the design and manufacture of Messrs. Mousell, Brothers & Wood, of Birmingham. There was no foliated embossing about these elegant vase supports, which were simply clasped here and there with the real foliage. All was angular, slight (not over slight), and exceedingly tasteful. The whole set was designed, *en suite*, very cleverly, the style being perfectly preserved in every feature of the supports of the little button-hole vases. The basis of the design in all the pieces was principally founded, in its details, on the Greek "key pattern," and the connecting lines were graceful and appropriate. The floral part of the decoration was sufficiently good to show off to advantage this pretty decorative service of plated ware, but does not call for further comment.

Table No. 9 was furnished by Mr. J. Cypher, of Queen's Road, Cheltenham. It was quite *sui generis*. Instead of aiming at graceful effects in the way of careless grouping, and seeking symmetry rather through well-balanced irregularities than by means of positive repetitions of parts both in form and colour, Mr. Cypher had rushed into the bedding system, and given us charming floral pincushions, instead of deliciously careless natural combinations. He had, however, done his work so well, that, at the first glance, one was compelled to admit that the effect was chaste, neat, and pleasing in a high degree, though founded upon the most unartistic kind of formalism. The base of the epergne was a mirror in which the bordering of maidenhair fern and a few flowers were reflected as in water. In the first tazza above the base we had—first, a regular circle of neat scarlet flowers; then a regular uninterrupted circle of beautiful white flowers, within which was again another circle, consisting of deep crimson ones; this triple and somewhat formal circle being lightened and relieved by sprays of *Spiraea japonica* and feather grass, which certainly modified the formalism very pleasantly. The second tier tazza contained an external circle of a light pink *Erica*, then one of deep damask roses, and then one of white roses. This was very pincushiony, and yet very neat and pretty. The upper tazza was filled with the delicate white-stemmed flowers of the ever-attractive *Spiraea japonica*, relieved with a single band of scarlet Pelargoniums. The two side vases were furnished in an entirely analogous manner—equally formal and unartistic, but equally neat and attractive; and the selection of colours was sweetly harmonious and reposeful. The smaller floral features of the table were, perchance, much more free in character. To this table was awarded the first prize, and perhaps justly so.

The 10th set of table decorations was arranged and exhibited by Mr. C. H. Harrison. The centre ornament consisted of a tall glass vase, somewhat too lumpy in character, mounted on a silver stand; in it were arranged Pelargoniums and Fuchsias, lightened by well-disposed grasses. At the sides were growing plants in pots; the pots concealed in pretty chip encasements. The only original feature consisted in low trough trays, in neat shapes, prettily filled round the edges with flowers of compact form and growth.

On the whole, the ten table displays were very pretty, and showed a growing love of flowers as graceful accompaniments to the more material and necessary features of our repasts. This taste has doubtless a refining influence, and ought to be carefully and sedulously cultivated for that, if for no other, reason; but while glancing at the *morale* of the case, we should be careful, in the interests of our artistic perceptions, which are among the more delicate of our mental gifts, not to overdo floral decoration, and so create a vulgar taste for profusion instead of that more refined artistic instinct, which naturally seeks for and appreciates the delicate proportions and symmetry of art rather than lavish profusion, even if the lavishness be stamped by the genius of a Rubens.

In the luncheon tent, the tables were very gracefully decorated with cut flowers, and small, elegant plants, including palms and Dracennas. Miss Blair won the first prize with a few very simple

materials charmingly arranged. She used no plants whatever, and her cut flowers consisted of water lilies, *Eucharis*, a branchlet of *Passiflora princeps*, a small semi-double white peony, and a few flowers of scarlet pelargoniums. These few flowers, gracefully seated in a few well-placed ordinary ferns and common hedgegrow grasses, produced a most charming effect. Some might think that the result was marked by poverty; but few could deny the great taste shown in several of the vases on the Prince's table, of which the plate, &c., was by Elkington & Co., of Birmingham and London.

DRAWING-ROOM DECORATIONS AND BOUQUETS.

The arrangement of flowers in drawing-room vases was not abundantly illustrated on this occasion, but there were, nevertheless, several very charming examples exhibited.

Mr. R. S. Yates, of Sale, Cheshire, furnished a glass tazza of very choice flowers, which no arrangement or mis-arrangement could spoil. In fact, the glass tazza and the silver epergne which supported it, combined with the rare beauty of the flowers, among which were several of the grandest orchids, was, perhaps, one of the finest things in the exhibition, as a group of noble flowers; but the arrangement presented no feature of novelty, and scarcely the average amount of taste; and, therefore, in the light of drawing-room decoration, it could not of course be deemed worthy of high praise; though the fronds of a grand *Adiantum* drooped so gracefully round the bouquet of noble flowers that they made beauty by the sheer force of their irresistible grace.

Mr. S. Evans, gardener to C. N. Newdegate, Esq., had a graceful three-tier composition of flowers for the drawing-room. The lower part of the central glass column was gracefully enough enriched with a spray of orchid flowers; and the summit, at the upper tier, was formed of a delicate plume of grass-bloom—a little *Aira* quivering at the slightest breath; but, on the whole, the composition was not entirely successful.

The most exquisite thing of the show in this department was, however, the charming composition of Miss A. Hassard. The three-horned glass epergne which that lady employed was very graceful in itself, but it was the floral dressing, the fascinating millinery of flowers, that clothed it with its truest graces. In the saucer at the base there were only three simple water lilies; but they were placed with a *finesse* of taste that showed the hand of the true artist, their green surroundings being equally graceful. In the trumpet mouths of the three glass horns there were simply half-a-dozen blue corn flowers (*Centauria Cyanus*), the dazzling azure of which was subdued and rendered more charming by two or three white sweet peas, just as the too dazzling summer sky is sometimes delicately obscured by great white fleecy clouds. These simple flowers, the same in each of the horns of glass, were modestly harboured among a few delicate fronds of maidenhair fern; while a delicate plume of quivering grass-bloom, mingled with white Rhodanthe, was the elegant crown of this composition; beautiful in form, colour, disposition, and "simplicity"; it deservedly carried off the first prize.

Mrs. Hassard had a beautiful piece of drawing-room flower-grouping, which was barely superior to that of Miss Blair, but a few final touches of excellent import secured the favour of the judges, who placed it just in front of Miss Blair's pretty group, assigning to it the second prize. In the saucer, gracefully fern-framed, crimson Cacti alternated with white water lilies, and the plume of feathering grasses in the vase above, figured very effectively; and blending very felicitously with the delicate grasses were a few sprays of white Rhodanthe.

Miss E. Blair exhibited a graceful trumpet-shaped vase and bouquets springing from a saucer, in which the only flowers were white lilies, jauntily disposed among ferns and mosses; the flowers in the mouth of the vase being sparingly introduced as in the saucer below. The merit consisted not in the rarity or variety of the flowers, but in their consummately graceful disposition. This tasteful floral structure was rewarded well with the third prize in this section of the show.

Mr. T. Wotton, gardener, Wirksworth Hall, had a fine low drawing-room bouquet of very choice flowers, but it was somewhat too compactly arranged; and the same may be said of a good epergne of flowers contributed by Mr. Fowkes, gardener to Mr. Humphries, of Kidderminster; and Mr. Chard had a graceful bouquet vase, which was a very bevy of exquisite roses exceedingly well arranged.

One of the finest examples of hand-bouquets was contributed by Messrs. Pope, of King's Norton; and there were fine bouquets of this kind shown by the Messrs. Fellows, of Birmingham. Some rather smaller ones were sent by Mr. Yates, of Sale, one of which, with a grand purplish-marked *Laelia* as a central object, was very beautiful. There were others sent by Mr. Turner, of Liverpool, which were worthy of admiration; one of them had a charming half open rosebud for its centre, and the rest of the mass was lightened by sprays of white *Spiraea*, and sweetly straggling bits of *Oncidium*; the edge being strikingly relieved by half-showing points of dark, richly variegated leaves. Miss E. Turner sent an equally charming bouquet.

BUTTON-HOLE BOUQUETS.

Of these, there was a very extensive little show; the general defect in these miniatures is, that in the effort to make them so very attractive, they are often made too big. Nothing is so successful as a single flower, when the single flower is good enough; for instance, a choice orchid with a tiny spray of maidenhair fern. They should be gems, mounted in fairy filagree, a diamond, a sapphire, a ruby,

an opal, any of them may be fair or even surpassed among our flowers. But, although strongly advocating a single flower as a button-hole bouquet, there were yet some very charming combinations, scores of them indeed sent in from many quarters. We will, however, only mention one—it was formed of three small double white pinks, with forget-me-nots between—a real jewel formed of floral pearls and torquises, nestling within a miniature spray of a lovely fern.

STOVE AND GREENHOUSE PLANTS.

PASSING to Stove and Greenhouse Plants, as a matter of course, we might say that Mr. Baines held the place of honour, and though some of his plants have been mentioned before, there were some which may be named again with advantage. First among these were the noble *Sarracenia*, all grand plants, which impart a new character to collections. *Dipladenias* were also good, and we were glad to see more a finely bloomed plant of *D. splendens*. *Phoenicocanths* were well grown and finely coloured; and the same may be said of the *Ixoras*. *Statice profusa* and *Allamanda nobilis* made a fine contrast. *Hedera taurifera* was finely bloomed, and the same may be said of *Dracophyllum gracile*, a sheet of white bloom. Opposite these was a smaller group from Mrs. Cole & Son, of Manchester, among which *Ixora Colei* was especially conspicuous, and fully maintained the character it had already earned ; back of this was a fine fresh plant of *Azalea Extranea*, a complete mass of bloom.

In the group of smaller plants, Mrs. Cole & Son had some nice fresh specimens well grown. In Messrs. Jackson's group we noted *Dracophyllum gracile*, some very nice Heaths, and one or two old friends, such as *Clerodendron Kämpferi*, and *Rondeletia speciosa major*. Messrs. Jackson had also a fine *Pimelea spectabilis*, a glorious *Erica Douglaei*, and some other very fine Heaths. Messrs. Bell & Thorpe had nice, well-grown *Statices* and *Allamandas*; *Eucharis amazonica* was well shown in one or two groups, notably a specimen from Mr. Coyle; *Clerodendron Balfourianum* was well shown, a dense mass of bloom, by Mr. Chapman; and the same exhibitor had *Ixora amboynensis*, finely coloured. The dwarf variety of *Sobralia macractha*, shown in fine condition by Mr. J. Webb, of Stoke, near Coventry, every shoot having a spike of bloom, was a good example of high-class cultivation. The same exhibitor had a fine, clean, fresh plant of *Stephanotis floribunda*. Another plant, which took strangers captive, was *Mussaenda frondosa*, with its sheets of white bracts, studded with small yellow stars; though an old plant, this is the finest specimen we have seen, and was shown by Mr. Shuttleworth. Of Heaths, Messrs. Jackson, of Kingston, had fine plants as usual. Mr. Baines had fine plants of Heaths also, and won the first prize in the amateurs' class; among them we noted a promising young specimen of the true *Erica obtusa*, and fine specimens of other good kinds.

Mr. B. S. Williams showed a number of noble palms, with which he deservedly took a first prize.

Miscellaneous collections contained objects of great interest; foremost amongst which may be mentioned a group from Messrs. Veitch & Son, of Chelsea. This comprised *Dioscorea* retusa, trained on an umbrella-shaped trellis; three plants of *Dieffenbachia*, *Bausei*; various examples of the newer kinds of *Dracaenas*, such as *D. magnifica*, a deep copper-coloured kind; *D. Chelonioides*, possessing a rich dark metallic lustre, bordered with red; *D. Weismanni*, a graceful kind, with narrower foliage than the former; and *D. amabilis*, something after the form of *D. Gulifolii*, but much finer. There were also *D. Youngii*, a greenish copper-coloured plant; and *D. MacLeayi*, pendant in habit, and very dark in colour. Of Crotons there were also several very fine kinds. In this group, too, there were a few excellent seedling *Gloxinias*, whose richly coloured large flowers were much admired. There were also several *Nepenthes*, bearing pitchers of great size and beauty; some handsome palms and ferns; amongst the latter may be mentioned *Lomaria zamiae-folia*, a rare kind from Monte Video, with large foliage densely covered with brown hair. Particularly noteworthy, too, was the pretty little *Phallus thalictroides*, with its beautiful Adiantum-like foliage. Many pretty fine-leaved plants, such as *Bertoloniopsis*, *Sonerilias*, *Dichorizandras*, and *Fittouias* also found a place in this valuable group. Mr. B. S. Williams, of the Paradise Nurseries, Upper Holloway, contributed some pretty little ferns, such as *Gymnogramma grandiceps*, a nicely crested golden kind; *G. Wetenhalliana*, a dwarf silver kind; *Pteris triocarpa*, a fern of which we see too little; and many others, besides a few good filmy ferns; this collection also contained palms, *Zamias*, *Anthuriums*, and succulents. A fine collection of *Ixias* and other ornamental Cape bulbs was shown by Messrs. Barr & Sugden from their experimental grounds at Tooting, where they inform us they have beds of these, as well as of *Tritonias*, *Babianas*, and *Sparaxis*, which they annually plant early in spring in light

soil at a depth of four or five inches or so, and which thus treated thrive and bloom admirably. If planted in September, October, or November they will not do so well, unless they are rather carefully protected. Messrs. James Carter & Co. had a very extensive stand devoted to seeds, plants, &c., in which were beautiful fern stands and drawing-room ornaments.

ORCHIDS.

ALTHOUGH, as a whole, orchids were fairly shown, they were not so numerous as might have been expected. Most of them consisted of well-known species, yet amongst them were some rare and particularly interesting subjects. Of these we may mention the lovely *Masdevallias*, of which two species, viz., *M. Veitchii* and *Harryana*, were exhibited by Messrs. Veitch in fine condition than we remember to have seen them. Another very interesting orchid was a hardy *Cypripedium*, named *C. Irapeanum*, from Messrs. Backhouse & Son, of York. This beautiful plant is about fourteen inches high, the leaves being woolly, and of a light green colour; the flowers are yellow, slightly tinged with reddish purple in the centre, and very large and handsome. Single specimen orchids were scarcely what might have been expected, for amongst some of the collections were superior plants to those exhibited in this class. There was a particularly well-bloomed plant of *Phalaenopsis grandiflora*, and fine examples of *Saccobodium guttatum* and *Dendrophylax filiforme*. In the nurserymen's class for six exotic orchids, were a few magnificent plants, such as *Saccobodium promorsum*, with five fine flower spikes, and good specimens of different *Aérides*, and *Cypripediums*. Here, again, we noticed that grand specimen of *Saccobodium guttatum Holifordianum* that we have so often seen at the London shows. Besides this fine specimen, Mr. Williams contributed several others, amongst which was a very purely coloured variety of *Lexia purpurata*, and a nice healthy plant of *Aérides Larpentii*, which, though not at its best as regards expanded flowers, promised, in a week or two, to be wonderfully fine. The collection of nine exotic orchids (furnished by Mr. J. Hodges, Gravelly Hill) contained a very fine specimen of *Epidendrum vitellinum majus*, whose lovely orange-red flower spikes, of which there were five on one plant, contrasted admirably with others in this collection, in which was likewise a good plant of the wax-like flowered *Cypripedium villosum*, one of the most showy and about as free flowering a kind as any in its class. In the collection of Messrs. Rollisson & Sons, of Tooting, was a fine plant of *Dendrobium clavatum*, and one of *D. Dabbenianum*. Amongst a splendid collection of miscellaneous plants exhibited by Messrs. Veitch & Son were several fine examples of orchids, such as *Trichopilia lepida*, a rather new and beautiful kind, with a deep rose throat; *Epidendrum Pseud-epidendrum*, a curious species with green sepals, but with a rose-coloured lip; *Cycnoches gratiosum*, with curious, minutely spotted blooms of a brownish lilac, or mauve colour; and a grand example of *Dendrobium Bensoniae*, with lovely white blooms. Besides these was a plant of *Epidendrum piliferum*, more curious than beautiful, and one of the pretty lilac coloured *Thunia Bensoniae*. Amongst a grand collection from Mr. B. S. Williams were several fine orchids, such as *Aérides crispa*, *Cattleya Warnerii*, and *C. lobata*, with very large flowers. Mr. Williams also exhibited as new orchids *Aérides Ellisi*, a kind producing fine spikes thickly set with large deeply coloured flowers; and *Lissochilus Krebsii*, a nice yellow-flowering kind, producing very tall flower spikes. Cut flowers of orchids were plentifully used both in trusses of cut-blooms of stove and greenhouse plants, and in the formation of bouquets and table ornaments.

NEW PLANTS.

As a whole this class did not contain as much novelty or merit as we should have expected, though Messrs. Veitch had a fine collection of their best new plants; among the most remarkable novelties was a fine plant of *Tasconia exoniensis*, from Mr. Veitch, of Exeter. It is a very beautiful cool greenhouse climber; a most distinct cross, effected by Mr. Robert Veitch, between the splendid *Tasconia Van Volxemi* and *T. mollissima*. The tube is at least two and a half to three inches long, and the flower a beautiful light magenta, with a purple ring in the centre. *Nertera depressa*, a beautiful minute New Zealand plant, about one inch in height, hardy, or very nearly so, was shown by Mr. E. Holmes, of Lichfield. It was covered with orange-coloured berries, densely produced among the small leaves, like miniature oranges. It will prove a beautiful cool greenhouse or cold frame plant, and may prove hardy in mild districts near the sea. The finest new plant of the show, however, was a noble Mexican yellow Lady's Slipper (*Cypripedium Irapeanum*). This, however, did not seem to have been noticed by the judges on the first day. A beautiful new plant, too, is *Anectochilus Ortigesianus*, from New Granada. Mr. Maw's fine introduction, *Iris tingitana*,

was also shown in flower. Messrs. Backhouse showed *Iberis Pruitti*, a good rock plant. Some beautiful *Athyriums* are also well worthy of notice among new hardy ferns, and there were many new varieties in this popular class. The finest hardy alpine plant, however, was Mr. George Maw's fine *Saxifrage florula*, spoken of elsewhere. The new bronze tricolor *Pelargoniums*, shown by Messrs. Downie, Laird, & Laing, were remarkably beautiful and good. The best were Prince Arthur, Climax, and Mrs. E. A. Pollard. A collection of the same plants also received first prize, and included a remarkably fine variety called W. E. Gumbleton, and various others distinct and beautiful. Mr. C. Perry's new *Verbenas* were well worthy of admiration. Prince Arthur, a first-rate zonal *Pelargonium*, was shown by Mr. Turner, of Slough, and Mr. Laing seemed to us to be one of the finest, if not the finest, of silver tricolors. Among new hardy variegated trees, was the variegated Weeping *Sophora*, a gracefully-growing pretty variety. Lilies, after a long period of neglect, are at last coming into favour in a way that their most enthusiastic admirers would not have dreamt of ten years ago. Not only are people beginning to seek out and grow the best old kinds, but new species and varieties are being introduced every day. The representatives of the family here were well deserving of special notice. G. F. Wilson, Esq., of Weybridge, Surrey, exhibited the finest specimens of *Lilium Brownii* we ever saw. Mr. Wilson also showed a species of lily from America allied to *L. superbum*: it has, however, the petals more rolled back than those of that species; the upper half of the petals is of a rich crimson; the lower half rich yellow freely spotted with dark brown. The plant is of a free majestic habit, and grows vigorously in Mr. Wilson's garden. This species was found by Mr. Robinson near Moore's Flat, in the Sierra Nevada, California, in one of the beautifully wooded ravines that occur so frequently there. It grew on the banks of a small rivulet which trickled along the bottom, associated with herbaceous *Aralias* in a position rather densely shaded by large trees of *Arbutus*, fine large-leaved evergreen oaks, and giant *Thujas*. Another beautiful one shown by Mr. Wilson is *L. umbellatum citrinum*, of a rich orange apricot colour, and perfectly free from spots. The name is probably not correct: it is no doubt a variety of *L. Thunbergianum*; Messrs. Barr & Sugden, of London, showed *L. Thunbergianum aurum nigrum maculatum*, a rich soft orange apricot, the lower half of the petals freely covered with black spots. This variety varies much in colour. Various other interesting lilies came from the same house, as, for example, *L. umbellatum punctatum*, a rich orange, shading off towards the point of the petals to crimson and freely marked with black spots. Mr. Ware, of Totternhoe, showed in excellent condition that fine old-fashioned lily, *L. croceum umbellatum maculatum*, in colour crimson, shading off to yellow, and free from spots, and various other striking varieties.

PELARGONIUMS.

THESE were numerously furnished, both in the form of specimens and small plants. Both show and fancy kinds seemed to have been grown more naturally than hitherto; but in point of size and profusion of bloom, they scarcely equalled the specimens seen about London. Amongst the smaller plants in this class, however, were some possessing great merit, the blooms being well-formed and superbly coloured. Amongst those from Mr. Turner, of Slough, we noticed grand plants of *Sultana*, *Achievement*, *Pompey*, *Brigand*, and others. New tricolor, bronze, and zonal varieties were numerously shown, but owing to the great resemblance which they bear to kinds already in existence, it is difficult to distinguish in what their novelty consists. A brilliantly coloured tricolor, named *Gem of Tricolors*, was shown by Mr. Kimberley, of Stoke. The following new bronze kinds of considerable merit were also shown, viz.: Climax, Prince Arthur, F. D. Quilter, W. E. Gumbleton, and others. Specimens of zonal *Pelargoniums*, both single and double, were tolerably good; but with regard to the double ones especially, we expected to have seen better flowered plants. From silver and other variegated foliated sorts, all flowers had been removed.

ROSES.

Roses, contrary to expectation, were shown in good condition, although not in the best phase of their beauty. The most successful exhibitors were, among the nurserymen, Mr. Cant, of Colchester; Mr. George Paul, of Cheshunt; and Mr. Charles Turner, of Slough. Mr. Cranston, of Hereford, was too late in making his entry, but brought a fine collection of flowers, which were shown with the intimation that they were "not for competition;" and, among amateurs, Mr. Evans, gardener to C. N. Newdegate, Esq., took precedence—doing honour to his county with excellent collections of roses; closely followed by Messrs. Laxton, Perry, and others. Mr. George Paul exhibited a charming collection of roses in pots, just such as amateurs may grow and ought to grow, with some half-dozen healthful beautiful roses on each. The

best of these were the Baroness Rothschild, La France, Beauty of Waltham, Monsieur Noman, Xavier Olivo, Caroline de Sansal, Centifolia Rosea, Louis Van Houtte, Edouard Morren, John Hopper, Mdle. Thérèse Levet. It is too early for new roses, but we admired "Annie Laxton," raised by Mr. Laxton, of Stamford, a compact, well formed and pleasing kind.

CONIFERS.

ONE of the most graceful features of the show was a great number of handsome young conifers and other evergreens. Some of these were shown for prizes by such famous growers as Mr. W. Barron, Mr. J. Standish, and a local grower, Mr. Vertegans, of Edgbaston, (who had many excellent specimens); amongst others (not shown for competition) was a beautiful collection shown under canvas by Mr. Smith, of Worcester. This was worthy of the famous nurseries whence it came. Specimens of *Hedera Rægeriana*, in the form of compact but not too low or formal bushes, were among the most distinguished (as Frenchman would say) evergreens we have ever seen. There was also a good specimen of the capital evergreen oak (*Quercus austriaca sempervirens*). Among variegated privets in Mr. Smith's collection, was the new and excellent variegated form of *Ligustrum ovalifolium*. Here also among many other objects of interest which want of space prevents us from enumerating, was a very interesting collection of rare and curious oaks in a small state. Messrs. F. & A. Dickson, of Chester, also contributed a good collection of evergreens, but not for competition; as did also Mr. Vertegans. In addition to those in the tents, various parts of the grounds were liberally embellished with handsome young conifers from the Royal Nurseries at Ascot.

Amongst the newer and more striking coniferous plants, we observed the following as being specially worthy of notice: in Mr. Standish's (of Ascot) collection, the *Abies obovata*, from the Altai Mountains, stood out prominently; it is quite hardy, and certainly one of the finest of the newer *Abies*. The *Rotinospora obtusa alba* and *R. pisifera plumosa variegata* seem useful and interesting varieties, as is also the *R. obtusa viridis*, which is a charming green variety. Messrs. Barron & Sons, of Borrowash Nurseries, Derby, exhibited some really important new kinds, amongst which the *Abies Engelmannii candidissima*, a beautiful compact-growing glaucous species from the Rocky Mountains, at once arrested attention; as did *Abies Tsuga nana*, from Japan, both seedlings raised by Messrs. Barron & Sons. The *Taxus baccata* Barronii was also a great acquisition amongst hardy variegated plants; this variety appeared to grow more vigorously than the old *Golden Yew*, which Messrs. Barron & Sons use extensively as a permanent bedding edging or line. The *Arthrotaxus taxifolia*, *A. selaginoides*, and *A. cupressoides*, all natives of Tasmania, were worthy of notice. Mr. Fowler, gardener to the Earl of Stair, at Castle Kennedy, exhibited young plants of a remarkably fine white seedling *Abies Douglasii*, which he has named *Abies Douglasii Stairii*. The foliage of this, as winter approaches, gradually changes to green. All the young growths burst forth nearly white the following spring, and about midsummer gradually change to a rich delicate cream colour. This tree is said to have a good constitution, growing nearly as fast as the common species. If so, it is destined to supply a much-felt want amongst coniferous trees, and lighten up many a landscape. In Mr. Barron's collection was a fine specimen of the elegant *Abies Alcoquiana*. It is likely to prove a finer grower than the hemlock spruce. A fine golden variegated *Pinus insignis* was also exhibited by the same firm; the variegation is not very strongly marked, but extends regularly through the plant.

SUCCULENTS.

UNTIL very recently it was rare to find at flower shows anything like a collection of these interesting plants. Now, however, through the influence of Mr. Peacock, of Hammersmith and others, such plants are often seen. The fine collection of them furnished by Mr. Peacock on this occasion was one of the most noticeable features of the exhibition, for in them thousands of Birmingham people witnessed a strange sight. Many would not even believe that they were in reality living plants, but considered them to be of artificial manufacture; and this supposition seemed to be strengthened by the very odd appearance which some of the grafted plants presented. The mystery connected with these plants was also heightened by the cuts severing the head, as it were, in some cases from the stock, making it appear to be next to impossible for one plant to live upon another when so circumstanced. In this famous collection, *Mammillaria nivea*, *lanifera*, *bicolor*, *cristata*, and *Parkinsonia* were particularly fine, as were also some nice plants of the "Old Man Cactus," *Pilocereus*. Of Agaves there are now several very beautiful small species, as might have been seen in this collection, or amongst the miscellaneous collector of plants shown by Messrs. Veitch and Williams. The fine

collection of succulents supplied by Mr. Ware, of Tottenham, and Messrs. Bell & Thorpe clearly illustrate what they are doing for us in the form of flower-garden decoration.

HERBACEOUS AND ALPINE PLANTS.

HERE for the first time herbaceous and alpine plants were shown in a manner worthy of their beauty and interest. Mr. Maw's collection alone would have made an exhibition of itself, so rare and valuable were many of the plants which it contained. We would particularly instance his superb *Saxifraga florulenta*, the greatest novelty among alpine and herbaceous plants at the exhibition. Most of the exhibitors in these classes deserve credit for the great improvement shown in their collections. The plants, however, were exhibited in the open air, and in consequence were very much disfigured by the heavy rains of Monday and Tuesday. Cut blooms of herbaceous plants were exhibited in beautiful order by Mr. Ware, of Tottenham; Mr. F. Perkins, of Leamington; and Messrs. E. J. Perkins, of Leamington; by Mr. John Jennings, Shipston-on-Stour; by Mr. George Maw, Bentham Hall, Broseley; and by Mr. Lakin, Chipping Norton. Messrs. Rollinson, of Tooting, showed the best grown collection of herbaceous plants. Mr. Ware's hardy variegated plants were also very fine, and those sent by the new exhibitors, Messrs. Bell & Thorpe, of Stratford-on-Avon, were excellent. One is glad to welcome any new exhibitors in these classes, and Messrs. E. J. Perkins, of Leamington, showed a remarkably well-grown group of alpine flowers, quite fresh and full of brilliancy. We were greatly surprised at the many fine collections of alpine flowers attracted here by the trifling prizes offered for such things, and have no doubt that ere long some of the most brilliant ornaments of our shows will be of this class. Mr. Peter Grieves had also his famous bronze ivy-leaved *Pelargonium* on the ground.

FRUIT.

THE fruit show was not first-rate. Pines and peaches were fine; grapes, with a few noble exceptions, were hardly up to the usual standard of excellence, either in size or colour. Only two collections of twelve dishes each were shown, the fruits in each collection being alike—two pines, twelve grapes, two peaches, two nectarines, two strawberries, and two melons. The Hamburgs in both collections were rather red, and neither the Foster's Seedling nor Muscats were ripe. In Mr. Mills' (gardener to Lord Carrington) collection, the melons (Royal Ascot and another), and the peaches, Violette Hative and Barrington, the Murray and Elrugo nectarines, and the pines, were noteworthy.

There was an excellent display in the class for three pines—eight or nine exhibitors contesting for the honour; Black Prince, and the Queen, being the most worthy of the same. The competition in single pines was not so keen, the same varieties again contending for the award. Mr. Smith and Mr. Cox had some of the best fruit in these classes, and Mr. Ward and others staged good fruit. For the best single dish of Black Grapes there was a spirited competition among twelve or more growers. Black Prince was the most perfect grape shown, in bunch, berry, and finish. There were some good Hamburgs, but those that were largest were rather deficient in colour, and the black ones were not distinguished by their size. In the best basket of twelve pounds there were several competitors, and two or three very fine lots exhibited, the most distinguished being a basket of Muscats shown by Mr. Smith (gardener to Mr. Blinkhorn, St. Helen's, Lancashire), who also showed a magnificent single dish of the same variety. There were over a dozen dishes of white grapes shown, but none of the Muscats were ripe, except the one dish noted, and perhaps next to these a dish of Muscadines, well ripened. Three bunches of Golden Champion were shown by Mr. Bannerman (gardener to Lord Bagot)—the berries were fine, but the fruits were hardly ripe, yet the spot which often ruins this promising grape was developing itself. A very fine basket of black grapes was shown by Mr. Broadbridge, of Warwick, and another, extremely well coloured, by Mr. Rawbone (gardener to the Earl of Shrewsbury, at Alton Towers). There was a fine display of peaches, by over two dozen competitors, and more than half the number seemed to deserve prizes. Nectarines were not shown in such numbers, neither were they quite equal in quality, though a few dishes were fine. Cherries were scarcely represented, and did not seem to have any special merit. The pouring rains we have had also seems to have left their stains on the strawberries, which were not distinguished by either colour or size. Melons were a large and uneven lot, and we never remember noticing such disparity in size, condition, and doubtless quality, among them; a great many of them very old. The best-looking fruit among them being the Ruddington Seedling, shown by Mr. Mitchell, a sort wonderfully like a medium-sized well-formed Queen Emma. It has been a rather trying season thus far for melons, and doubtless this fruit will

appear in finer flavour at the autumn shows. For pot vines Messrs. Lano, of Berkhamstead, seemed the only exhibitors, showing a Hamburg and a Foster's Seedling, laden with crops extraordinary for pot vines.

VEGETABLES.

THE show of vegetables was one of the most interesting features of the exhibition, and was on the whole very good. There were six competitors in the class for thirty pods of Mr. Paxton's new pea, Superlative. It is certainly a large pea, of a fine green colour—that is the pod—we cannot speak to its quality. The pods swell out very fast, so much so that the peas rattle within, failing to swell fast. It however, proved an interesting exhibition, and will, doubtless, develop into a valuable pea. For the collection of vegetables confined to gentlemen's gardeners of Warwickshire, Worcestershire, and Staffordshire—three prizes, amounting to £10, offered by the proprietors of the *Midland Counties Herald*—there was not much competition. The most interesting feature of the show, was the class of fifteen dishes of vegetables; this called forth a spirited competition, and a noble exhibition; eight entered the lists, and three or four lots ran a neck-and-neck race for first place. The competition in the class for the best six peas, inclusive of McLean's Best of All, was interesting and good, Mr. Cox holding a pre-eminent position in this class. Mr. Sutton's prizes for the best three cucumbers, to include the Marquis of Lorne, brought forth a fine display, no less than eleven or twelve showing three brace each, some of these remarkably fine. Blue Gown, Hamilton's Invincible, and the Marquis of Lorne being among the finest specimens. In the single brace class the Marquis also came well to the front, and some remarkably clean specimens labelled 'as grown in France,' appeared as if the climate agreed with them. The Messrs. Carter's challenge cup of the value of £52. 10s. seemed to have frightened gardeners, for only two competitors put in an appearance for it, viz., Mr. Gross, gardener to G. B. Lonsdale, Esq., Peak House, Devon; and Mr. Lumsden, Bloxham Hall, Lincoln. The peas in the latter exhibitor's collection were especially fine. Potatoes we were glad to see looking clean and free from disease, though they were somewhat smaller than usual, especially the round ones. Some very fine tomatoes were exhibited, and this quite added a brightness to this department of the show.

HOTHOUSES.

OR these there was a most interesting exhibition, though not so varied nor extensive as one could have wished. Many of the largest builders were not represented at all, but those who were there seem to have done their best. Three facts strike one at a glance: the first is the desire to rid of putty—there seems quite a rage for dry glazing; the second is the growing popularity of iron, either alone or combined with wood, for hothouse construction; and the third, the rage for small houses and portable glass contrivances of all kinds. Imperishability and portability seem to be the order of the day in our horticultural buildings. The permanent houses will stand for a life-time, and longer, with as little outlay for repairs as possible; and our tiny glass contrivances are whipped over crops as they grow, and off them again, with as much or more dispatch. Mr. Ayres showed capital examples of his houses. The walls and stages are formed by enduring cements, and the roof of iron and glass; the iron being nearly wholly covered with the glass, thus reducing the painting surface to a minimum. The glass also overlaps sideways, so that drip is thus disposed of, dirt under the laps is impossible. The glazier and the bricklayer are dispensed with; the ventilation is most perfect; and when the houses are perfected, they seem to merit the name of imperishable applied to them. Several examples were given, and they were also shown as frames, but for the latter they are too heavy; unless the frames are deep enough, or a sunk path is formed (as in Mr. Smeed's "poor man's house") to allow the workmen to walk under the glass, rather than lift it for watering, &c. Messrs. Howitt & Co., of London and Ilford, showed a good example of their light and elegant houses, heated and ventilated with Taylor's combined ventilating and vapourising pipe. The roof ribs of these houses are formed of hollow tubes, that fit into each other with a sort of socket, so that all screws, &c., are dispensed with; they are light and elegant in the extreme. The vapourising and ventilating are managed very simply; the nine first lengths of piping are furnished with a vapouring trough a little wider than the ordinary sort, these are then covered over with zinc, all but a small space of a few inches at one end; at the opposite end of each vapour trough a pipe is fixed, and led down through the walls into the open air. The cold air rushes in, and is carried the whole length of the vapour trough before it is liberated, and thus discharged through a ventilator in the apex, or through one or more zinc chimneys placed at one or both ends of the house for the purpose.

Messrs. Boulton & Co., of Norwich, exhibited a large assortment of

houses, garden chairs, tables, and watering-pots with new distributing contrivances of numerous kinds. These manufacturers also exhibited good substantial wooden houses of various kinds. Their lantern conservatory is lofty, and conveys the idea of a waste of space above the roof proper; but the other houses are plain and business-like, and the system of roof ventilation by the raising of the ridge is excellent. The universal plant preserver is held together with iron ribs, the roof ends of which form an eye for the lights to be hooked on to other preservers; they are worked by lifting them to any required height from the front, or turning one side right over on the other—a handy and most convenient arrangement. The Messrs. Dennis & Co., of Chelmsford, showed two nice houses, a highly-ornamental conservatory, and their five-pound greenhouse; the light and elegant style of these buildings is well known, but the cheap house is made of the best yellow deal, painted once, and is 10 feet long, 5 feet wide, 7½ feet high at the back, and 5 feet in front, and is a neat, serviceable, roomy house for the money. Mr. Thomas Bickly, of Birmingham, had a nice exhibition of his light and pretty houses. The glass is held in by strips of zinc running across the houses; these are deeply serrated on each side like the teeth of a coarse saw; the glazing consists in turning up one half of the teeth on each side, to retain and hold the glass in position; the serrated bar above is patented and fitted to either an iron or wooden ribbed house of any description. These houses are marvellously improved since first shown.

HOTHOUSE BOILERS.

THE boiler trials have proved a test as well of boiler capacity as of the enthusiasm of exhibitors and judges, for a succession of thunderstorms and drenching rains rendered stopping and testing matters of no easy accomplishment, there being no less than thirteen boilers, each heating one thousand feet of piping.

Mr. Cannell showed three of his hot-water circulators, one of a capacity of eighteen gallons, one of thirty, and a third of forty-six. The chief merit of these boilers is that they are expansive; if too small, another crown, which also forms another fine, is simply laid, and that to any extent, thus exhausting the caloric before it is allowed to escape; the connections are also all outside beyond reach of the fire, and the outside of the whole is encased with non-conducting material. Mr. Cannell also showed a number of boilers not on trial.

Mr. Edwin Lumley showed one of his Excelsior boilers for trial; it seemed very powerful with a great volume of vertical flame playing round a very little water, conditions likely to be favourable to economical heating.

Messrs. Hartley & Sugden, of Halifax, showed two powerful-looking improved saddle boilers on the trial field, and a large assortment, on the opposite side of the grounds, of their tanks, independent saddle boilers, domed top boilers with sand rims, independent conical and improved saddle boilers, altogether a very extensive and most interesting collection.

The Messrs. Dennis & Co., of Chelmsford, tried two of their tubular boilers, which are merely a series of pipes placed horizontally and joined at the four corners by others running up vertically. These form a boiler of any height or size required, and are well spoken of on the trial field. The same may be said of Green's patent hot-water boiler, a most powerful-looking arrangement for giving the water in a series of narrow shelves an uneasy time of it. A great variety of these boilers, with mowing-machines, &c., will also be found in the implement shed. The Whitley Court boiler looked powerful, and likely to do any amount of work with certainty. Mr. Deards, of Harlow, in Essex, challenged all comers, and tested his boiler on the trial field.

A patent centrifugal heating apparatus is the only true circulating boiler in existence, reducing the consumption of fuel to a minimum; its chief feature seems to consist in the thrusting of a coil of pipe into the fire, which plays round it, to the forcing forth of the water in the basin to go about its proper business. There is one great subject of regret, that several of our largest makers have stood aloof from this trial, and some may think any trial of boilers comparatively worthless that does not include such boilers as those of Weeks, Ormsom, the Trentham, Gray, Jones, and others. Several of these were well-represented at the show sheds, and Mr. Weeks had an imposing display in another part of the grounds.

Mr. Ormsom showed a good example of the old convoluted boiler, and one with the addition of a water-way under the fire bars, as well as a new Premier Flued Cornish Boiler. Some good examples of Stevens' Trentham Boilers were exhibited by Mr. Fenton. The Messrs. Green also exhibited new saddle boilers cased with wood to retain the heat.

Mr. Mee, of Liverpool, exhibited a new patent heating apparatus, which aims to save fifty per cent. of fuel, and is well spoken of by

those who have used it. There is a plate at front, which seems well adapted to arrest and economise heat.

Mr. Thomas Nock, of Andover Street, Birmingham, showed several varieties of gas-stoves, admirably adapted for heating frames, small houses, and conservatories. The air to feed the fire is taken from the outside, and of course no gas is permitted to enter the house.

DISTRIBUTION OF MEDALS.

On Wednesday his Royal Highness Prince Arthur again visited the show for the purpose of distributing the medals. He walked to the large tent, and made a minute inspection of its principal contents, particularly of Mr. George Paul's roses; and from his observations, which were of a very discriminating character, it is evident he takes a deep interest in and possesses considerable knowledge of floriculture. After walking through several of the other tents, his Royal Highness proceeded to the covered dais, around which was a large assemblage of spectators, and distributed such of the medals as had been awarded. The names of the successful competitors were called out by General Scott, Mr. E. W. Badger handing the medals to the Prince, who delivered them to the recipients, accompanied with a few words of congratulation to each.

PRIZES FOR HOUSES, IMPLEMENTS, &c.

GOLD MEDALS—Messrs. W. Howitt & Co., Great George Street, Westminster, for the best horticultural building. Mr. Frederick Reynolds, Broad Street, Birmingham, for the best collection of garden furniture. Messrs. Maplebeck & Lowe, Birmingham, for the best collection of garden machinery, tools, &c. Messrs. George Baker & Co., Aston Road, Birmingham, for the best collection of garden wirework.

SILVER MEDALS—Messrs. Cranston & Luck, Highgate Street, Birmingham, for collection of horticultural buildings. Messrs. Dennis & Co., Chelmsford, for conservatory, 1,099. Messrs. Hill & Smith, Dudley, for wirework.

BRONZE MEDAL—Messrs. W. S. Boulton & Co., Norwich, for portable plant preservers.

In addition to the awards enumerated above, we may mention the following:—

Messrs. W. S. Boulton & Co., Rose Lane Works, Norwich, a silver medal for their collection of garden engines and machinery.

Messrs. Fellows & Bate, Manchester, a silver medal for the patent Anglo-American law-mower.

Messrs. Thomas Haynes & Sons, Edgware Road, London, a silver medal for their patent garden hose.

Messrs. Erwart & Son, Euston Road, London, a silver medal for their collection of flower boxes and plant cases.

Mr. W. F. Chapman, a silver medal for his collection of cases for cut flowers, fruit, &c.

Messrs. Maplebeck & Lowe, a bronze medal for garden ornaments and furniture.

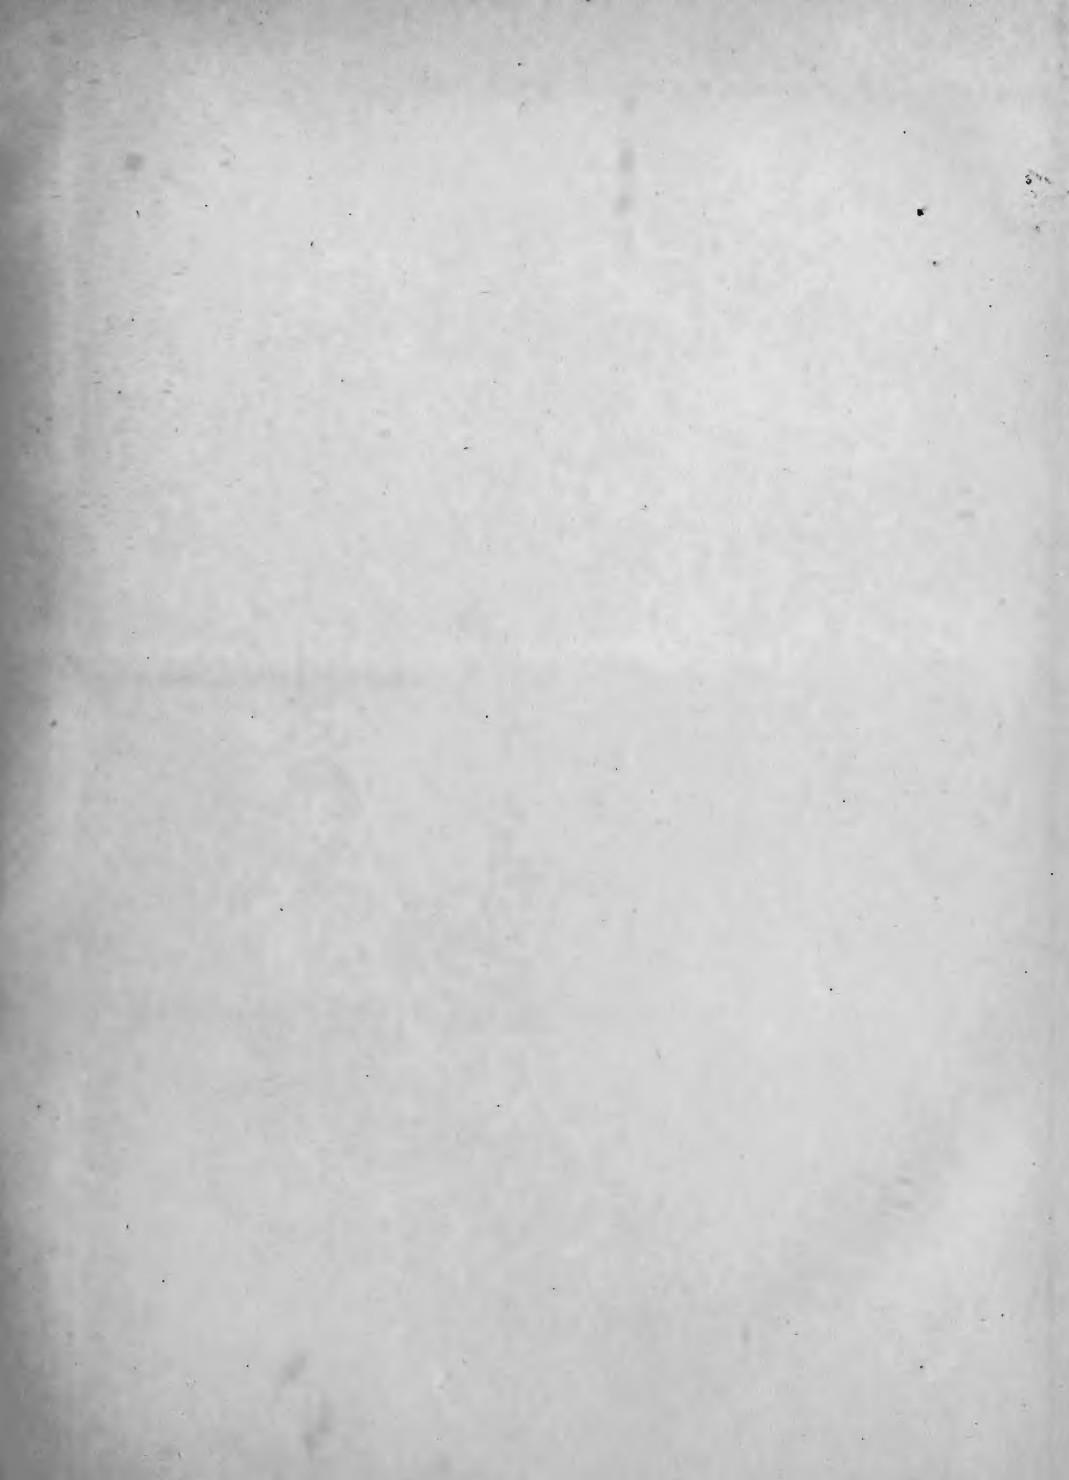

Messrs. Henry Bamford & Sons, Uttoxeter, a bronze medal for an improved water-barrow.

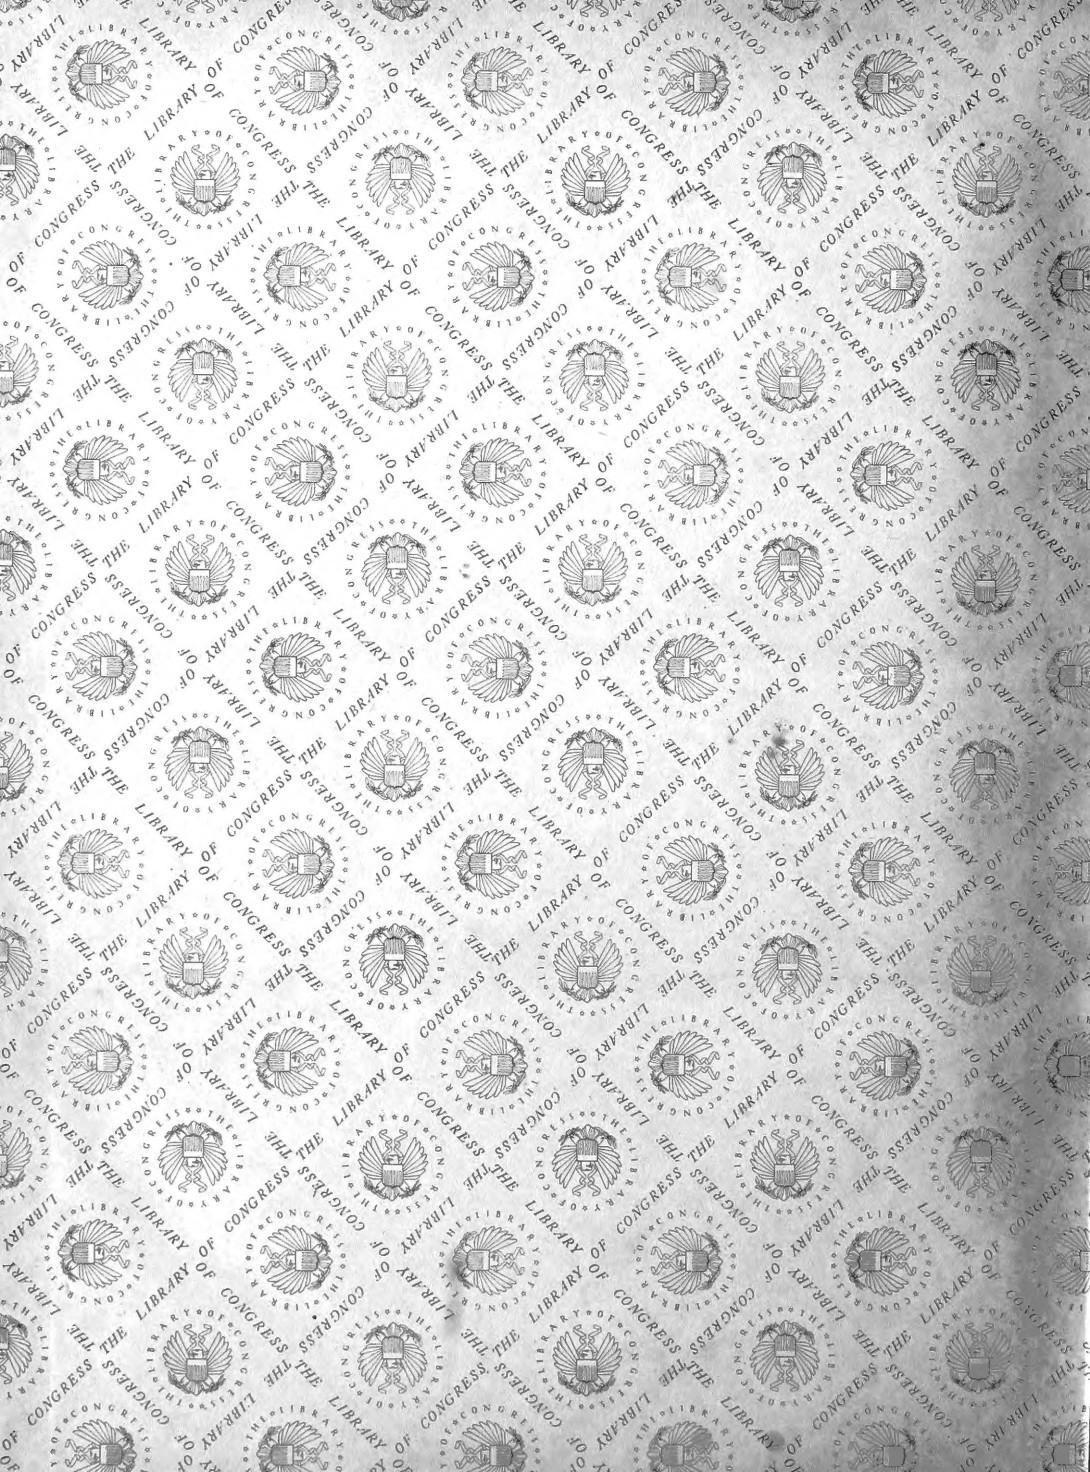

We may add that Messrs. Howitt's house, which obtained the gold medal, is thirty feet by seventeen feet, constructed and exhibited by the patentees. This is a simple, serviceable, light, elegant, well-ventilated, and cheap building. It appears to comprise all the requirements of such an edifice, and was considered by the judges to be worthy of a gold medal. The shape of the house in section is arched, the main supports or ribs being of 1½ inch wrought-iron straight tubes, in short lengths, joined together by wrought-iron sockets at such an angle as will give the necessary curve to the roof. There is no outward thrust, and hence there are no tie rods to offend the eye or interfere with the space. The ribs carry light horizontal bearers, which are stiffened by light wrought-iron stays, and support wood or iron sash bars; the glazing is effected without laps, each opening having one square, which is putted in, any condensed moisture being discharged outside. The ventilation can be effected in all weathers, the lower squares of glass being fixed in frames, which are opened by a lever with horizontal rods and jointed arms; the bearings are of gun-metal. The frames can be connected or disconnected at pleasure, so as to give whole or partial ventilation. The upper squares, also in frames, are hinged to ridge, and opened and closed by rods and arms worked by the very slow process of cog wheels and worm. This is the only unsatisfactory feature about the house, and one which should be remedied to render it perfect.

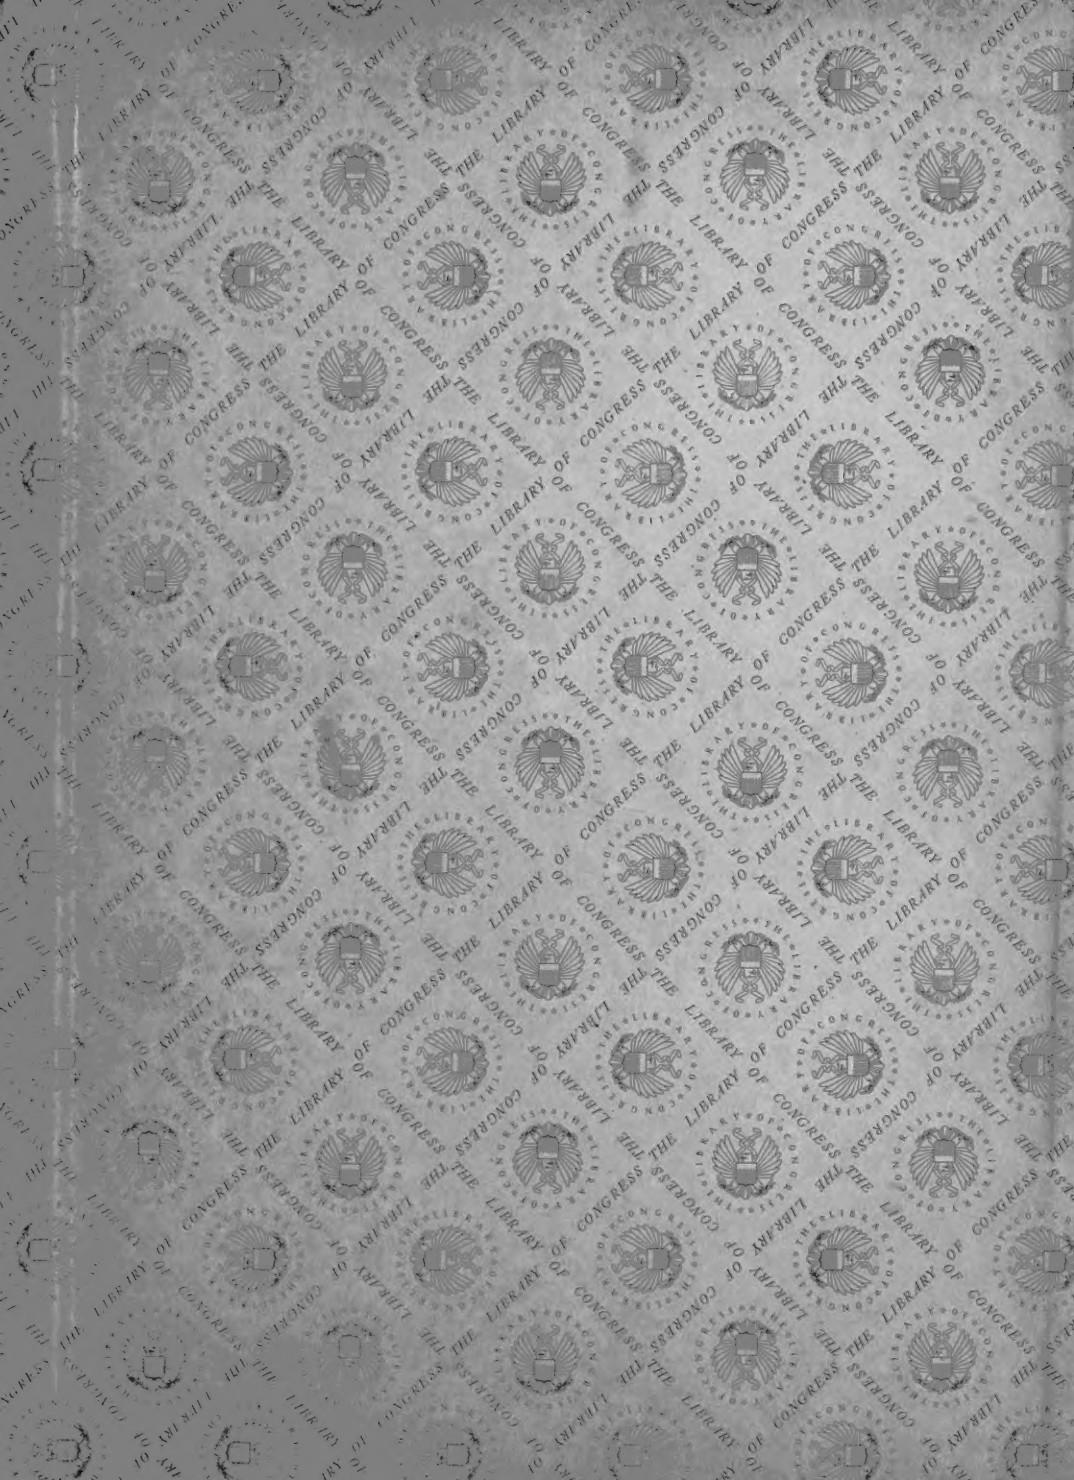

We cannot close our account of this great gardening exhibition without testifying to the courtesy and ability with which the honorary secretary, Mr. Badger, carried out and brought to a successful issue all the details of this great show. We, in common with all the horticultural community, are greatly indebted to him. Mr. Hallam, who so well carried out all the details of the garden structure and boiler department, also deserves our hearty thanks. Owing to the weather, and owing also, we think, to allowing the public to enter the grounds to the inconvenience of the judges, other matters will have to be postponed till next week.
